[2] *Poole, S. et al. (2012). WHO international standard for endotoxin: report of an international collaborative study to evaluate three preparations of endotoxin for their suitability to serve as the third international standard for bacterial endotoxin. World Health Organisation.*

Type of product	Route of administration	*K*	
		per person	per kg
All parenteral preparations	Intrathecal[1]	14	0.2
Radiopharmaceuticals	Intravenous	175	2.5
All parenteral preparations except intrathecal	All parenteral routes except radiopharmaceuticals	350	5.0

[1]Where a product can be administered both intrathecally and by another parenteral route, the more stringent value of *K* for the intrathecal route will be taken as the basis of establishing the ELC.

reactions. The appropriate value for *K* will be taken from the table below.

8.2 *M* is the maximum dose of the drug substance per person (or per kg) per hour. This is interpreted as the maximum amount that might be administered within one hour. For subcutaneous (SC), intramuscular (IM) or bolus intravenous (IV) injections this will be an entire single dose. For intravenous infusions given over a prolonged period it is the proportion of the dose that would be infused during one hour and depends upon the rate of infusion. The value used is the maximum dose recommended by the manufacturer and stated in the relevant product data sheet. It is accepted that in exceptional circumstances this dose may be exceeded at the discretion of the physician; such use is outside the scope of the Pharmacopoeia.

Implementation

9. The British Pharmacopoeia Commission is seeking to replace the test for pyrogens by that for bacterial endotoxins wherever possible in the Pharmacopoeia. The European Pharmacopoeia Commission has a similar policy and has indicated that, for monographs already published, the change will be carried out, where appropriate, whenever the monograph in question is revised.

9.1 The test for bacterial endotoxins is now specified in the European Pharmacopoeia monograph for Water for Injections and in many other monographs including a range of antibiotics (for example, Doxorubicin Hydrochloride and Oxytetracycline Hydrochloride), biological materials (for example, Somatropin and Heparin) and radiopharmaceutical preparations.

9.2 Revision of the European Pharmacopoeia monograph for Parenteral Preparations to permit the use of the test for bacterial endotoxins in defined circumstances opened the way for the test for pyrogens to be replaced by that for bacterial endotoxins in individual monographs for parenteral preparations in the British Pharmacopoeia. The necessary change has already been made in a wide range of monographs including those for certain biological formulations such as Protamine Sulfate Injection and in the monographs for a number of widely used intravenous infusions such as Sodium Chloride Intravenous Infusion. Appropriate data are being sought from manufacturers for the remaining monographs for which a test for pyrogens is specified.

Annex

Guidelines concerning the test for Bacterial endotoxins have been published as an Annex to the method text 2.6.14 in the European Pharmacopoeia and are reproduced here.

The following section is published for information.

Guidelines for using the Test for Bacterial Endotoxins

(Ph. Eur. general texts 5.1.10)

1. INTRODUCTION

Endotoxins from gram-negative bacteria are the most common cause of toxic reactions resulting from contamination of pharmaceutical products with pyrogens; their common pyrogenic activity is much higher than that of other known pyrogenic substances. These endotoxins are lipopolysaccharides. Although there are a small number of pyrogens that possess a different structure, the conclusion is generally justified that the absence of bacterial endotoxins in a substance or product implies the absence of pyrogenic components, provided the presence of non-endotoxin pyrogenic substances can be ruled out. The monocyte-activation test (*2.6.30*) is a suitable method to use to rule out the presence of non-endotoxin pyrogens in substances or products.

The presence of endotoxins in a substance or product may be masked by factors interfering with the reaction between the endotoxins, the test reagents and the amoebocyte lysate. Also, the ability to detect endotoxins may be affected by storage conditions or storage time. Hence, the analyst who wishes to implement a test for bacterial endotoxins or to replace the pyrogen test by a test for bacterial endotoxins has to demonstrate that a valid test can be carried out on the substance or product concerned; this may entail a procedure for removing interference.

As indicated in general chapter *2.6.14. Bacterial endotoxins*, information must be available on the following 2 aspects before a test on a sample can be regarded as valid.

— The suitability of the material to be used for the test has to be established. The absence of endotoxins in the water for BET (water for bacterial endotoxins test) and in the other reagents and consumables must be assured and the sensitivity of the amoebocyte lysate must be checked to confirm the sensitivity declared by the manufacturer.

— As the substance or product to be examined may interfere with the test, the sensitivity of the amoebocyte lysate is determined in the presence and in the absence of the substance or product to be examined. There must be no difference between the 2 sensitivity values.

General chapter *2.6.14. Bacterial endotoxins* indicates methods for removing interfering factors; in the case of interference, another test must be carried out after such a method has been applied to check whether the interference has indeed been neutralised or removed.

This general chapter explains the reasons for the requirements in the test for bacterial endotoxins, then deals with reading and interpretation of the results.

Replacement of the rabbit pyrogen test required in a pharmacopoeial monograph by an amoebocyte lysate test, or by other methods such as the monocyte-activation test or a test using recombinant factor C reagent as a replacement for the amoebocyte lysate, constitutes the use of an alternative method of analysis and hence requires demonstration that the method is appropriate for the given substance or product and gives a result consistent with that obtained with the prescribed method as described in the General Notices (see also section 13).

The prescribed method for bacterial endotoxins may be stated in the monograph on a given substance or product. The use of a method other than the method prescribed in the monograph is considered as the use of an alternative method. Where no method is stated, any of methods A to F of general chapter *2.6.14. Bacterial endotoxins* can be used.

2. METHOD AND ACCEPTANCE CRITERIA

2-1 METHODS AND PRECAUTIONS TO BE TAKEN

The addition of endotoxins to amoebocyte lysate may result in turbidity, precipitation or gelation (gel-clot); initially only the gel-clot method was used in the Pharmacopoeia as an evaluation criterion in the test for bacterial endotoxins. The advantage was the simplicity of basing the decision to pass or fail the substance or product to be examined on the absence or presence of a gel-clot, visible with the naked eye. The quantitative methods C, D, E and F were developed later: they require more instrumentation, but they are easier to automate for the regular testing of large numbers of samples of the same substance or product.

Endotoxins may be adsorbed onto the surface of tubes or pipettes made from certain plastics or types of glass. Interference may appear due to the release of substances from plastic materials. Hence, the materials used must be checked.

2-2 ENDOTOXIN LIMIT CONCENTRATION

The decision to use the test for bacterial endotoxins as a limit test implies firstly that an endotoxin limit concentration must be defined for the substance or product to be examined, and secondly that the objective of the test is to know whether the endotoxin concentration in the sample to be examined is below or above this limit. The quantitative methods C, D, E and F make it possible to determine the endotoxin concentration in the sample to be examined, but for compliance with the Pharmacopoeia and in routine quality control the final question is whether or not this concentration exceeds a defined limit.

The dose of the substance or product to be examined must be taken into account in setting the endotoxin limit concentration: the limit is set so as to ensure that, as long as the endotoxin concentration in the substance or product remains below this limit, even the maximal dose administered by the intended route per hour does not contain sufficient endotoxin to cause a toxic reaction.

When the endotoxin concentration in the substance or product exactly equals the endotoxin limit concentration, gelation will occur, as is the case when the endotoxin concentration is much higher, and the substance or product will fail the test, because the all-or-none character of the test makes it impossible to differentiate between a concentration exactly equal to the endotoxin limit concentration and one that is higher. It is only when no gelation occurs that the analyst may conclude that the endotoxin concentration is below the endotoxin limit.

For substances or products in the solid state, this endotoxin limit concentration per mass unit or per International Unit (IU) of substance or product has to be converted into a concentration of endotoxin per millilitre of solution to be examined, as the test can only be carried out on a solution. The case of substances or products that already exist in the liquid state (such as infusion fluids) is discussed below.

2-3 CALCULATION OF THE ENDOTOXIN LIMIT

The endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to:

$$\frac{K}{M}$$

K = threshold pyrogenic dose of endotoxin per kilogram of body mass;

M = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, M is the maximum total dose administered per hour.

The endotoxin limit depends on the product and its route of administration and may be stated in the monograph. Values for K are suggested in Table 5.1.10.-1.

For other routes, the acceptance criterion for bacterial endotoxins is generally determined on the basis of results obtained during the development of the preparation.

Table 5.1.10.-1

Route of administration	*K*
Intravenous	5.0 IU of endotoxin per kilogram of body mass
Intravenous for radiopharmaceuticals	2.5 IU of endotoxin per kilogram of body mass
Intrathecal	0.2 IU of endotoxin per kilogram of body mass
Parenteral formulations administered per square metre of body surface	100 IU of endotoxin/m^2

2-4 CONSIDERATIONS WHEN ESTABLISHING AN ENDOTOXIN LIMIT FOR A SPECIFIC SUBSTANCE OR PRODUCT

The endotoxin limit for a substance or product is established with consideration of the following aspects.

Calculated endotoxin limit

The endotoxin limit is calculated as described in section 2-3. This represents a safety limit not to be exceeded if the product is to be administered to humans.

Limit prescribed in an individual substance monograph

The limit stated in an individual substance monograph frequently reflects what is achievable in a controlled production environment. The limit prescribed in a monograph can therefore be lower than the calculated endotoxin limit. However a manufacturer may specify a limit that is more stringent than that stated in the monograph.

Process capability

The capability of the process to reduce or remove bacterial endotoxins during manufacture might result in lower endotoxin limits for specific processes.

Additional safety requirements

Precautions are taken in consideration of patient population (such as paediatric use, malnourished or cachectic patients, etc.), specific local requirements (e.g. countries might wish to operate with a lower average body weight of 60 kg instead of 70 kg frequently employed in Europe) or any additional safety margins requested by the competent authority.

Formulation of the product
The limit must take into consideration any theoretical bacterial endotoxin load introduced by any other components used for reconstitution and/or dilution of the product (e.g. water for injections) or introduced by starting materials and/or raw materials.

2-5 MAXIMUM VALID DILUTION
Which dilution of the substance or product is to be used in the test to obtain maximal assurance that a negative result means that the endotoxin concentration of the substance or product is less than the endotoxin limit and that a positive result means that the lysate detected an endotoxin concentration equal to or greater than the endotoxin limit? This dilution depends on the endotoxin limit and on the sensitivity of the lysate; it is called the maximum valid dilution (MVD) and its value may be calculated using the following expression:

$$\frac{\textit{endotoxin limit} \times \textit{concentration of test solution}}{\lambda}$$

Concentration of test solution:
— in mg/mL if the endotoxin limit is specified by mass (IU/mg);
— in Units/mL if the endotoxin limit is specified by unit of biological activity (IU/Unit);
— in mL/mL if the endotoxin limit is specified by volume (IU/mL).

λ = the labelled lysate sensitivity in the gel-clot technique (IU/mL) or the lowest concentration used in the standard curve of the turbidimetric or chromogenic techniques.

When the value of the MVD is not a whole number, a convenient whole number smaller than the MVD may be used for routine purposes (which means preparing a solution of the substance or product that is less diluted than the MVD indicates). In this case, a negative result indicates that the endotoxin concentration of the substance or product lies below the limit value. However, when the endotoxin concentration of the substance or product in such a test is less than the endotoxin limit but high enough to make the reaction with the lysate result in a clot, the test may be positive under these conditions. Hence, when a test with this 'convenient' dilution factor is positive, the substance or product is diluted to the MVD and the test is repeated. In any case of doubt or dispute, the MVD must be used.

This stresses the importance of the confirmation of the sensitivity of the lysate.

Example

A 50 mg/mL solution of phenytoin sodium (intended for intravenous injection) has to be tested. Determine the MVD, given the following variables:

M = maximum human dose = 15 mg per kilogram of body mass;
c = 50 mg/mL;
K = 5 IU of endotoxin per kilogram of body mass;
λ = 0.4 IU of endotoxin per millilitre.

$$MVD = \frac{5 \times 50}{15} \times \frac{1}{0.4} = 41.67$$

For routine tests on this product, it may be expedient to dilute 1 mL of the solution to be examined to 20 mL (MVD/2 rounded to the next lower whole number). However, if this test result is positive the analyst will have to dilute 1 mL to 41.67 mL and repeat the test. A dilution to 41.67 mL is also necessary when the test is performed to settle a dispute.

3. RISK ASSESSMENT

As stated in section 1 of this general chapter, the conclusion is generally justified that the absence of bacterial endotoxins in a substance or product implies the absence of pyrogenic components, provided the presence of non-endotoxin pyrogenic substances can be ruled out. To rule out the presence of non-endotoxin pyrogens in substances or products, the use of the monocyte-activation test (*2.6.30*) is recommended at release or during development of the production process; if any changes are made to the production process that could influence the quality of the product regarding pyrogenicity, the monocyte-activation test is repeated. Examples of such changes include the use of different raw materials, a different production site and different process parameters.

The decision to use the test for bacterial endotoxins as the sole pyrogenicity test is to be made after careful evaluation of the risk of the substance or product containing non-endotoxin pyrogens. The risk assessment is made with consideration given to any factor that could result in the inclusion of pyrogens not detected by the test for bacterial endotoxins. The items below constitute a non-exhaustive list of factors to be considered in the risk assessment.

Production process
(chemical synthesis, fermentation, biotechnological method). For products of fermentation, the expression system is to be considered (prokaryotic, eukaryotic) and, for a prokaryotic expression system, whether gram-positive or gram-negative bacteria are used. Also, the culture media components are examined with consideration given to their origin (synthetic, animal, plant).

Bioburden
The potential presence of gram-positive bacteria and fungi as contaminants of the active substance, excipients or starting materials and raw materials used in the production of the medicinal product, and the origin of the raw materials (synthetic, animal, plant) have to be taken into consideration. The quality of the water plays an important role on the overall evaluation.

Capability of the downstream process
It must be verified whether bacterial endotoxin removal steps are part of the downstream process.

Safety
The target population and the route of administration (e.g. intravenous, intrathecal) have to be taken into account in the risk assessment.

Stability of the detectable endotoxins
It has to be considered that the ability to detect endotoxins can be affected by interaction with certain components, storage conditions or storage time, temperature and handling of the test sample. Procedures that demonstrate stability of the detectable endotoxin content have to be established for storing, handling and mixing of samples.

4. REFERENCE MATERIAL

Endotoxin standard BRP is intended for use as the reference preparation. It has been assayed against the WHO International Standard for Endotoxin and its potency is expressed in International Units of endotoxin per vial. The International Unit of endotoxin is defined as the specific activity of a defined mass of the International Standard.

For routine purposes, another preparation of endotoxin may be used, provided it has been assayed against the

International Standard for Endotoxin or the BRP and its potency is expressed in International Units of endotoxin.

NOTE: 1 International Unit (IU) of endotoxin is equal to 1 Endotoxin Unit (EU).

5. WATER FOR BET

Water for BET is sterile water that is free of detectable levels of endotoxin. Usually it is commercially available and certified.

General chapter *2.6.14. Bacterial endotoxins* indicates that methods other than triple distillation may be used to prepare water for BET. Reverse osmosis has been used with good results; some analysts may prefer to distil the water more than 3 times. Whatever method is used, the resultant product must be free of detectable bacterial endotoxins.

6. PH OF THE MIXTURE

In the test for bacterial endotoxins, optimum gel-clot occurs for a mixture at pH 6.0-8.0. However, the addition of the lysate to the sample may result in a lowering of the pH.

7. VALIDATION OF THE LYSATE

It is important to follow the manufacturer's instructions for the preparation of the solutions of the lysate.

The positive end-point dilution factors in gel-clot methods A and B are converted to logarithms. The reason is that if the frequency distribution of these logarithmic values is plotted, it usually approaches a normal distribution curve much more closely than the frequency distribution of the dilution factors themselves; in fact it is so similar that it is acceptable to use the normal frequency distribution as a mathematical model and to calculate confidence limits with Student's *t*-test.

8. PRELIMINARY TEST FOR INTERFERING FACTORS

Some substances or products cannot be tested directly for the presence of bacterial endotoxins because they are not miscible with the reagents, they cannot be adjusted to pH 6.0-8.0 or they inhibit or activate enzymatic reaction (such as β-D-glucans).

Therefore a preliminary test is required to check for the presence of interfering factors; when these are found the analyst must demonstrate that the procedure to remove them has been effective and that by applying this procedure, any bacterial endotoxins present have not been removed.

The object of the preliminary test is to test the null hypothesis that the sensitivity of the lysate in the presence of the substance or product to be examined does not differ significantly from the sensitivity of the lysate in the absence of the product. A simple criterion is used in methods A and B: the null hypothesis is accepted when the sensitivity of the lysate in the presence of the product is at least 0.5 times and not more than twice the sensitivity of the lysate by itself.

The test for interfering factors in gel-clot methods A and B requires the use of a sample of the substance or product in which no endotoxins are detectable. This presents a theoretical problem when an entirely new product has to be tested. Hence, a different approach was designed for quantitative methods C, D, E and F.

Note that methods D and E, which use a chromogenic peptide, require reagents that are absent in methods A, B, C and F, and hence compliance of methods A, B, C or F with the requirements for interfering factors cannot be extrapolated to method D or method E without further testing.

9. REMOVAL OF INTERFERING FACTORS

The procedures to remove interfering factors must not increase or decrease (for example, by adsorption) the amount of endotoxin in the substance or product to be examined. The correct way of checking this is to apply the procedures to a spiked sample of the substance or product to be examined, that is, a sample to which a known amount of endotoxin has been added, and then to measure the recovery of the endotoxin after the removal process has been conducted.

Methods C and D

If the nature of the product to be examined results in an interference that cannot be removed by classical methods (e.g. dilution or centrifugation), it may be possible to determine the standard curve in the same type of substance or product freed from endotoxins by appropriate treatment or by dilution of the substance or product. The endotoxins test is then carried out by comparison with this standard curve.

Ultrafiltration with cellulose triacetate asymmetric membrane filters has been found to be suitable in most cases. The filters must be properly validated, because under some circumstances cellulose derivatives (β-D-glucans) can cause false positive results.

Another option to remove interfering factors is a 2-step procedure in which 1) endotoxin within the interfering sample is fixed on a solid phase, and 2) after removal of the interfering substance (e.g. by washing) the endotoxin is detected unimpaired under suitable testing conditions.

10. THE PURPOSE OF THE CONTROLS

The purpose of the control made up with water for BET and the reference preparation of endotoxin at twice the concentration of the labelled lysate sensitivity is to verify the activity of the lysate at the time and under the conditions of the test (for method A and B). The purpose of the negative control is to verify the absence of a detectable concentration of endotoxin in the water for BET.

The positive control, which contains the product to be examined at the concentration used in the test, is intended to show the absence of inhibiting factors at the time and under the conditions of the test.

11. READING AND INTERPRETATION OF RESULTS

Minute amounts of bacterial endotoxin in the water for BET, or in any other reagent or material to which the lysate is exposed during the test, may escape detection as long as they do not reach the sensitivity limit of the lysate. However, they may raise the amount of bacterial endotoxin in the solution containing the substance or product to be examined to just above the sensitivity limit and cause a positive reaction.

The risk of this happening may be reduced by testing the water for BET and the other reagents and materials with the most sensitive lysate available, or at least one that is more sensitive than the one used in the test on the product. Even then, the risk of such a 'false positive result' cannot be ruled out completely.

12. IMPLEMENTATION OF METHODS DESCRIBED IN THE PH. EUR.

As stated in the General Notices, the test methods given in monographs and general chapters have been validated in accordance with accepted scientific practice and current recommendations on analytical validation. The methods described in general chapters *2.6.14. Bacterial endotoxins*, *2.6.30. Monocyte-activation test* and *2.6.32. Test for bacterial*

endotoxins using recombinant factor C therefore do not have to be re-validated *per se*, other than in consideration of their use for a specific substance or product in a specific analytical environment.

The procedure and the materials and reagents used in the method must be validated as described for the test concerned.

The absence of interfering factors (and, if necessary, the procedure for removing them) is verified on samples of at least 3 production batches.

As stated in general chapter *2.6.30. Monocyte-activation test*, the monocyte-activation test is primarily intended as a replacement of the rabbit pyrogen test. Guidelines on which methods to use (A, B or C) and on how to validate the monocyte-activation test are described in general chapter *2.6.30. Monocyte-activation test*.

13. REPLACEMENT OF A METHOD PRESCRIBED IN A MONOGRAPH

13-1 REPLACEMENT BY ANOTHER METHOD DESCRIBED IN THE PH. EUR.

Replacement of a method prescribed in a monograph by another method described in the Ph. Eur. is to be regarded as the use of an alternative method in the replacement of a pharmacopoeial test, as described in the General Notices.

The analyst has to demonstrate that a valid test can be carried out on the substance or product concerned.

The alternative method does not have to be re-validated *per se*, other than in consideration of its use for a specific substance or product in a specific analytical environment and of its equivalence to the prescribed method.

13-2 REPLACEMENT BY A METHOD NOT DESCRIBED IN THE PH. EUR.

Replacement of a method prescribed in a monograph by a method not described in the Ph. Eur. is to be regarded as the use of an alternative method in the replacement of a pharmacopoeial test, as described in the General Notices.

D. Excipients

1. The General Notice on Excipients states that 'any substances added in preparing an official preparation shall... not interfere with the assays and tests of the Pharmacopoeia'.

2. The British Pharmacopoeia Commission wishes to stress that any preparation described by a name at the head of a monograph in the current edition of the Pharmacopoeia, *whether or not it is referred to as BP*, is not of pharmacopoeial quality unless it meets all of the requirements of the monograph when tested by the methods set down.

3. It is recognised that new formulations of existing preparations may from time to time be developed and that the excipients and other ingredients used might result in interference with the official assays and tests. In such cases the Commission is prepared to consider modification of methods to overcome the difficulties thus caused.

4. When seeking modification manufacturers are invited to submit details of the nature of the interference together with proposals for change that will allow the valid testing, by an independent analyst, not only of the proposed new formulation *but also of all similar preparations already on the market*. Practical evaluation in the Laboratory will usually be necessary before any amendments to a British Pharmacopoeia monograph can be considered. It is therefore in the interests of a manufacturer to submit any proposals at the earliest possible date.

E. Dissolution Testing of Solid Oral Dosage Forms

This section provides information on the pharmacopoeial dissolution test and guidance on its function and application in individual monographs of the British Pharmacopoeia for tablets and capsules.

1. Harmonisation

1.1 The dissolution test for solid oral dosage forms in Appendix XII B1 of the British Pharmacopoeia is that of the European Pharmacopoeia (*Ph. Eur. method 2.9.3*). It is a harmonised text prepared by the Pharmacopoeial Discussion Group (PDG). The PDG is comprised of representatives of the European Pharmacopoeia, Japanese Pharmacopoeia and the United States Pharmacopeia. Although the test is largely harmonised, some regional differences remain.

1.2 The British Pharmacopoeia has committed to modernising Monographs containing dissolution acceptance criteria that are not currently harmonised with the test in Appendix XII B1. Appendix XII B1 contains a section entitled *Monographs of the British Pharmacopoeia* which provides requirements for monographs for tablets and capsules of the BP that are yet to be updated. Taking account of permissible assay ranges and content uniformity, this pharmacopoeial (that is, shelf-life) dissolution requirement is considered to offer an acceptable degree of assurance of 'complete dissolution'. The choice of a time is, of necessity, somewhat arbitrary but 45 minutes is considered satisfactory for the majority of conventional-release (non-modified-release) products.

2. Apparatus

2.1 Four types of apparatuses are now described in the British and European Pharmacopoeias; the basket, the paddle, the reciprocating cylinder and the flow-through cell. The descriptions are concordant with those published in the United States Pharmacopeia (USP).

2.2 Of the two established apparatuses (basket and paddle) the paddle is now the apparatus of choice for many preparations. However, where a published test uses the basket, work to validate a change to the paddle method is not contemplated. The reciprocating cylinder is useful for pH profiling studies while the flow-through cell may be appropriate for preparations of poorly soluble active ingredients (see Appendix XII B Annex).

3. Test conditions and acceptance criteria

3.1 **Test conditions** The harmonised test conditions included in Appendix XII B1 will be applied to all monographs of the British Pharmacopoeia over time. Where an individual monograph prescribes the use of the requirements stated under *Monographs of the British Pharmacopoeia* in Appendix XII B1, the following conditions using the basket or paddle apparatus are preferred.

— rotation speed:100 rpm (basket), 50 rpm (paddle)
— dissolution medium volume: 900 mL
— dissolution medium composition: aqueous, commonly 0.1M *hydrochloric acid* or phosphate buffers of pH 6.8 to 7.6
— number of units tested: 6 (plus 6, if a retest is required).
— The number of units tested is specified in Appendix XII B1; other conditions are specified in the relevant individual monographs.

In situations where it has been demonstrated that the harmonised criteria are not applicable (e.g. low solubility preparations, 'coning' of material in the vessel, low concentration of analyte), modifications may be made to the test conditions, such as, adding a surfactant, increasing the paddle rotation speed or using a modified vessel and reducing the volume of dissolution medium used.

3.2 **Acceptance criteria** For monographs for conventional-release preparations, unless otherwise stated, the harmonised acceptance criteria ("Q" values) in Appendix XII B1 should be applied.
For monographs that are yet to be updated to "Q" values, the established BP criteria using either the basket or the paddle apparatus are specified under 'Monographs of the British Pharmacopoeia' in Appendix XII B1.

3.3 Standardised conditions and limits are considered appropriate for a pharmacopoeial test that is intended to apply to monographs covering products from different manufacturers. It might be argued that non-standardised conditions and limits would be more discriminatory but 'tailor-made' test conditions and limits may introduce product bias and may discriminate unnecessarily between products that are equally acceptable from a clinical view-point. Similarly with sufficient manipulation of the test conditions, dissolution of almost any product can be achieved. Ideally the test should reflect clinically significant differences in bioavailability arising from differences in dissolution in such a way that clinically acceptable formulations will pass whereas clinically unacceptable formulations will fail.

3.4 Another issue that has been considered in relation to test conditions and criteria is that of multiple-point dissolution profiles as opposed to single-point dissolution tests. It has been concluded that for conventional-release preparations such an extension of testing is not generally necessary or appropriate for pharmacopoeial purposes.

4. Function

4.1 The ultimate objective of dissolution testing may be described as ensuring adequate and reproducible bioavailability without recourse to routine *in-vivo* testing. On some occasions, this may be achieved by dissolution testing of a particular product for which *in vitro/in vivo* correlation has been demonstrated.

4.2 A more common objective of dissolution testing is to obtain information about the drug release characteristics of a particular formulation or batch of product under standardised *in vitro* testing conditions.

4.3 Dissolution testing may also be carried out during product development studies and is a useful tool in optimising formulation and manufacturing parameters. It is usually required by the Competent Authority as part of a marketing authorisation application.

4.4 Once a product is licensed, dissolution testing may be required routinely as part of quality control to demonstrate consistency of manufacture before the release of each batch of the finished product or, when necessary, to provide evidence to support changes in manufacture such as minor changes in formulation or process, changes in site or changes in immediate packaging materials.

5. Application

5.1 The British Pharmacopoeia Commission has not adopted a policy of universal application of the dissolution test and, therefore, a dissolution requirement will not be included automatically in every capsule and tablet monograph. The International Conference on Harmonisation (ICH) guideline on Test Procedures and Acceptance Criteria for New Drug Substances and New Drug Products (ICH Q6A) contains guidance on the application of dissolution testing to drug products and this will be used as a basis for deciding whether to include a dissolution test in an individual monograph.

5.2 As a *general guideline*, it is expected that all new monographs for conventional-release capsules and tablets will contain a dissolution requirement except (i) where the solubility of the active ingredient at 37 ± 0.5° is high throughout the physiological pH range (dose/solubility volume <250 mL at pH 1.2 to 6.8); (ii) where the dissolution of the dosage form is greater than 80% in 15 minutes at pH 1.2, 4.0 and 6.8; (iii) where a relationship has been determined between disintegration and dissolution, or when disintegration has been observed to be more discriminatory than dissolution.
In circumstances where conditions (i) to (iii) have been satisfied, the dissolution test may be replaced by the *disintegration test for tablets and capsules*, Appendix XII A1.

5.3 If challenged, a product would be expected to comply with the test for dissolution specified in the individual monograph, or if none is specified, with the Test conditions and acceptance criteria outlined in section 3.

5.4 Dissolution tests have been added to a considerable number of monographs in the British Pharmacopoeia. While the objective is to include a 'standard' pharmacopoeial test wherever appropriate, the circumstances for each preparation are considered individually in consultation with the manufacturers. It should be appreciated, however, that the retrospective addition of dissolution tests is not without its difficulties. The problems are most acute for those well-established preparations that are manufactured by a wide range of companies, each with its own dissolution specification. A pragmatic approach is being taken to developing compromise test procedures in these circumstances.

6. Bioavailability and Bioequivalence

6.1 Compliance with the standard British Pharmacopoeia requirement for dissolution provides an assurance that most of the active ingredient will be dissolved in a reasonable amount of time when the preparation is subjected to mild agitation.

6.2 It should be noted that compliance with the pharmacopoeial dissolution test does not by itself guarantee bioavailability and is not necessarily an adequate basis for judging bioequivalence between preparations. Preparations having similar dissolution characteristics may not be bioequivalent and *vice versa*.

7. Application of harmonised dissolution limits ("Q" values)

7.1 Since the harmonisation of the dissolution test through the Pharmacopoeial Discussion Group and the adoption of harmonised dissolution criteria ("Q values") between the European, United States and Japanese Pharmacopoeias, the BP Commission has received

many queries regarding the application of limits to dissolution tests.

7.2 As an aid to analysts several worked examples are provided as an illustrative guide below.

7.3 An immediate-release tablet formulation has a limit of Q = 75%. Six units are tested.

Unit	Result (% of stated amount)

3	80
4	88
5	90
6	82

In order to pass S1, all units must be greater than or equal to (Q + 5)% (i.e. 80%). Hence, the above batch passes at S1.

7.4 An immediate-release tablet formulation has a limit of Q = 75%. Six units are tested.

Unit	Result (% of stated amount)
1	77
2	87
3	70
4	88
5	90
6	82

Since units 1 and 3 are less than (Q+5)% (i.e. 80%), the batch fails at S1. A further six units must then be tested.

Unit	Result (% of stated amount)
7	78
8	85
9	79
10	84
11	87
12	85

In order to pass S2, the mean of twelve units must be greater than or equal to Q and no unit can be less than (Q – 15)% (i.e. 60%). The mean of the twelve units is 83% so this passes at S2 and, units 1 and 3, whilst failing at S1, are not less than (Q – 15)%, so this batch passes at S2.

7.4 An immediate-release tablet formulation has a limit of Q = 75%. Six units are tested.

Unit	Result (% of stated amount)
1	77
2	87
3	70
4	88
5	76
6	79

Since units 1, 3, 5 and 6 are less than (Q+5)% (i.e. 80%), the batch fails at S1. A further six units must then be tested

Unit	Result (% of stated amount)
7	73
8	85
9	79
10	84
11	87
12	58

Because unit 12 is less than (Q – 15)% (i.e. 60%) the batch fails at S2. A further twelve units must then be tested.

Unit	Result (% of stated amount)
13	79
14	83
15	67
16	84
17	80
18	82
19	78
20	85
21	84
22	81
23	83
24	88

In order to pass S3, the mean of 24 units must be greater than or equal to Q , not more than two units can be less than (Q – 15)% (i.e. 60%) and no unit can be less than (Q – 25)% (i.e. 50%). The mean of the 24 units is 80% so this passes at S3. Only unit 12 is less than (Q – 15)% and none are less than (Q – 25)% so this batch passes at S3.

7.6 An immediate-release capsule formulation has a limit of Q = 75%. Six units are tested.

Unit	Result (% of stated amount)
1	83
2	82
3	80
4	79
5	49
6	77

Since unit 5 is less than (Q – 25)% (i.e. 50%), the batch would fail at S3. Testing further units will not enable this batch to pass the test.

7.7 An immediate-release capsule formulation has a limit of Q = 75%. 24 units have been tested.

Unit	Result (% of stated amount)
1	76
2	82
3	80
4	79
5	70
6	77
7	65
8	69
9	77
10	73
11	68
12	71
13	79
14	65
15	70
16	72
17	67
18	83
19	63
20	68
21	74
22	71
23	75
24	70

All the units are greater than (Q – 15)% (i.e. 60%), however; because the mean (73%) is less than Q, this batch fails at S3.

F. Declaration of Content

This section describes the way in which the content of active substance in a preparation is declared and the method adopted to express the content of the medicinal substances themselves. A proper understanding of such statements is essential to their correct interpretation.

Medicinal substances

1. The purpose of the assay in monographs for medicinal substances, taken in conjunction with the tests for impurities, is to determine the purity of the medicinal substance and the limits are therefore usually stated in terms of the molecular entity (salt, ester, etc.) and calculated with reference to the anhydrous or dried substance as appropriate (depending on whether the monograph includes a test for water or for loss on drying).

2. One advantage of this form of expression in 'parent' monographs is that it gives an indication 'at a glance' of the purity of the substance. For example (albeit an extreme example) the purity of Amitriptyline Embonate is stated as not less than 98.5% of $(C_{20}H_{23}N)_2,C_{23}H_{16}O_6$ calculated with reference to the anhydrous substance rather than as not less than 57.9% of $C_{20}H_{23}N$ calculated with reference to the anhydrous substance.

3. The mode of expression chosen for the 'parent' monograph in no way circumscribes that which may be used in the monograph for a preparation. There is no reason why the two should be the same and there is frequently good reason why they should be different. In the example of Amitriptyline Embonate, the assay limits for the preparation Amitriptyline Oral Suspension are stated in terms of amitriptyline, $C_{20}H_{23}N$ in the BP 2000.

Formulated preparations

4. The purpose of the assay in monographs for formulated preparations is to determine whether the content of the active ingredient is within acceptable limits of the labelled claim and the limits are therefore of necessity stated in terms of the moiety declared on the label as established by the manufacturer.

5. Every effort is made in the British Pharmacopoeia to achieve internal consistency within monographs, that is, to use the same terms for content statement, assay and label. The British Pharmacopoeia Commission, however, has no means of achieving external (inter-monograph) consistency since, unless it perceives there to be a potentially serious risk, it would not seek to obtain a change in a manufacturer's established practice. Problems arise when a manufacturer is not consistent or does not state clearly to what the strength refers and, in particular, when different manufacturers of the same preparation express the content in different terms.

6. Ideally in many cases where several salts or hydrated forms of the same drug substance are available, the label and dose (and therefore all monograph statements) should be in terms of the anhydrous free base or acid, that is, the active moiety, in order to facilitate comparison and equivalent dosage.

7. Implementation of such a policy would clearly require that each case should be judged on its merits since there would be instances when, for example, a different salt is considered as a different active moiety or where it would be misleading to suggest that two different forms are therapeutically equivalent. Nevertheless it is strongly recommended that as a general rule *for new drug substances*, doses and strengths of preparations should be expressed in terms of the active moiety.

8. Meanwhile, for established materials the Pharmacopoeia will continue to reflect current practice. In this respect it should be noted that the labelling requirements of the Pharmacopoeia are not comprehensive. Thus a monograph requirement to state the content of active ingredient in terms of the entire drug substance molecule does not preclude an additional indication of the content expressed in terms of the active moiety where such an indication is considered desirable.

G. Labelling

This section provides guidance on the status and interpretation of pharmacopoeial labelling sections.

1. The General Notice on Labelling distinguishes between the mandatory status of those Pharmacopoeial labelling statements that are necessary to demonstrate compliance with the monograph and the advisory status of other labelling statements included in the Pharmacopoeia.

2. This distinction, which is consistent with the approach adopted in the European Pharmacopoeia, is made in recognition of the complexity of the statutory and advisory framework within which the labelling of medicines is determined. It is hoped that by thus restricting mandatory pharmacopoeial labelling statements to those that are essential for pharmacopoeial purposes, the potential for conflict between pharmacopoeial and other statutory provisions will be minimised.

3. Within the context of any particular monograph, it should be apparent which of the labelling statements are necessary to demonstrate compliance with the monograph and are thus mandatory. As guidance, a labelling statement is considered essential for a medicinal substance

(i) where a test or assay requirement is expressed in relation to a declared value, the 'labelled claim' (for example, the apparent viscosity of Carmellose Sodium or the potency of Calcitonin (Salmon));

(ii) where different test requirements or limits apply to materials derived from different sources (for example, the requirements for matter insoluble in 5M ammonia depend on the botanical source of Podophyllum Resin), or intended for different purposes (for example, the sterility of Benzylpenicillin Sodium when intended for use in the manufacture of a parenteral dosage form without a further sterilisation process);

(iii) in other special circumstances.

4. Likewise a labelling statement is considered essential for a formulated preparation

(i) where a test requirement is expressed in relation to a declared value, the 'labelled claim';

(ii) where the content of active ingredient is required to be expressed in terms other than the weight of the official medicinal substance used in making the formulation (for example, Primaquine Tablets contain Primaquine Phosphate but the content is expressed in terms of the equivalent amount of primaquine base);

(iii) where different test requirements or limits apply to the formulated preparation manufactured from different bulk drug substances (for example, Heparin Injection manufactured from Heparin Calcium or Heparin Sodium) or intended for different purposes (for example, Isosorbide Dinitrate Tablets intended to be

chewed before swallowing or allowed to dissolve in the mouth);

(iv) in other special circumstances.

5. Advisory labelling statements for formulated preparations may be included either in the general monograph or in the monograph for the individual preparation, as appropriate. Such statements commonly relate to features such as the expiry date, the storage conditions, the name and amount of any excipients and the directions for making the final preparations. Additional advisory labelling statements may relate to the directions for using the preparation or the precautions relating to the handling and use of the preparation.

H. Biological Assays and Tests

This section provides information and guidance concerning the biological assays and tests of the Pharmacopoeia and the standard preparations required for them.

1. Biological, including biochemical or immunochemical, methods are described for the determination of potency or other specific properties of certain substances and preparations where these properties cannot be adequately determined by chemical or physical means. The principle applied wherever possible throughout these methods is that of comparison with a standard preparation so as to determine how much of a sample being examined produces the same effect as a given quantity, the Unit, defined by the standard preparation. It is an essential condition of such methods that the tests on the standard preparation and on the sample, the potency or other property of which is being determined, shall be carried out at the same time and, in all other respects, under strictly comparable conditions.

2. Standard Preparations, as defined in the biological assays and tests of the Pharmacopoeia, are of two kinds: primary standards which are established, held and distributed by the appropriate international or national organisation and secondary (working) standards which are preparations the potencies of which have been determined by an adequate number of comparative tests in relation to the relevant primary standard.

3. A primary standard is a selected representative sample of the substance for which it is to serve as a basis of measurement. It is essential that primary standards shall be of uniform quality and as stable as possible. These conditions are usually ensured by providing the preparations in the dry state, dispensing them in sealed containers free from moisture and oxygen and storing them continuously at a low temperature and in the absence of light.

For the majority of biological assays of the Pharmacopoeia, the primary standards are the International Standards and Reference Preparations, established by the World Health Organization.

Laboratories in the United Kingdom may obtain these for the purposes of the biological assays described in the Pharmacopoeia from the National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QG, England.

In October 2005 the European Directorate for the Quality of Medicines & HealthCare (EDQM) was designated as the International Collaborative Centre for the establishment and distribution of WHO International Standards for Antibiotics (ISA) , replacing the National Institute for Biological Standards and Control (NIBSC) in this role. These standards may be obtained from the Sales Section, EDQM - Council of Europe, 7 allée Kastner, CS 30026, 67081 Strasbourg, France. Further information can be found on the EDQM website (www.edqm.eu).

For the assay of certain enzymes in the Pharmacopoeia the Standard Preparations, as defined in the appropriate method, are the primary standards established by the International Commission on Pharmaceutical Enzymes of the International Pharmaceutical Federation (FIP). These standards may be obtained from the Centre for Standards, Wolterslaan 12, B–9000, Ghent, Belgium or, where these standards have been established in co-operation with, and adopted as official preparations by, the European Pharmacopoeia Commission, they may be obtained from the EDQM address shown above.

4. As a measure of economy in the use of the primary standards it is recommended that working standards should be prepared and used in those biological methods of the Pharmacopoeia where the definition of the Standard Preparation is so worded as to permit this. However, in some instances the complexity or lack of precision of the method or difficulties associated with the preparation of a secondary standard render such a practice inadvisable and in any country in which a particular assay is controlled by law it may be necessary to obtain the approval of the appropriate authority for the use of working standards. The biological properties of the samples selected as working standards should conform as closely as possible to those of the primary standard and an assurance that these conditions have been fulfilled is usually obtained by comparing the behaviour of the two samples under varying conditions of comparative testing. In such tests a detailed study of the dose-response curves may indicate whether the sample selected to serve as a working standard is a suitable preparation. For the assay of certain biological materials in the Pharmacopoeia, for example oxytocin, European Pharmacopoeia Biological Reference Preparations have been established and are recommended for use as the working standards. Such preparations may be obtained from the European Pharmacopoeia Commission (address as above).

5. Wherever possible the primary standard is the International Standard, and the biological activity is expressed in International Units (IU). In other cases, where Units are referred to in the official assays and tests, the Unit for a particular substance is, for the United Kingdom, the specific biological activity contained in such an amount of the respective primary standard as the appropriate international or national organisation indicates. The necessary information is provided with the samples of the primary standard.

6. For enzymes in the Pharmacopoeia, where the assay is such that the stoichiometry of the reaction is known, for example, where the substrate is a synthetic ester, the activity is measured in microkatals or nanokatals. A microkatal is defined as the enzyme activity that under defined conditions, produces one micromole of the reaction product per second or alternatively consumes one micromole of the reaction substrate per second. For other enzymes in the Pharmacopoeia, where the reaction involved in the assay is more complex, for example, where the substrate is a naturally occurring macromolecule such as a protein, the activity is measured in Units as previously defined.

7. The methods of biological assay described in the Pharmacopoeia have been found satisfactory but will not necessarily be the best methods for use in all circumstances. In most instances they may be replaced by other methods if

it can be shown that such methods are at least equally accurate and precise and provide a measurement of the same active principles.

8. Any estimate of potency derived from a biological assay is subject to random error due to the inherent variability of biological responses and calculations of error should be made, if possible, from the results of each assay and recorded with the potency estimate even when the official method of assay is used. Guidance on the design of assays, the statistical analysis of results and the calculation of potency is provided in general text 5.3 of the European Pharmacopoeia (Supplementary Chapter IV G). The methods described therein take account of the inherent random error but assume that systematic errors, for example, errors in weighing or dilution, will not represent a major source of variation in the potency estimates. Alternative assay designs and methods of calculation may be used provided that they are not less reliable.

9. Where an immunoassay, that is an assay procedure based on the reversible and non-covalent binding of an antigen by antibody, is described in the Pharmacopoeia for detecting or quantifying either an antigen or an antibody, the considerations described in Appendix XIV B apply in addition to the general points referred to above.

J. Efficacy of Antimicrobial Preservation

This section provides background information on the purpose and scope of the test for efficacy of antimicrobial preservation. The Annex to this section provides guidance on some practical aspects of testing.

1. The test for efficacy of antimicrobial preservation, included in Appendix XVI C, has been accorded non-mandatory status in the Pharmacopoeia. This status is reflected in the test's inclusion as a general text in section 5 of the European Pharmacopoeia and in the form of reference to the test within Production sections of relevant general monographs of the European Pharmacopoeia. Non-mandatory status provides a degree of flexibility consistent with the intended purpose of the pharmacopoeial test.

2. The pharmacopoeial test is intended to serve as a model offering a manufacturer guidance concerning this aspect of quality and a foundation on which he can build to meet his own particular needs. The testing procedure is intended to serve as a means whereby, during product development, a manufacturer can assess the efficacy of any antimicrobial preservative included in the product. Within the context of the British Pharmacopoeia, Appendix XVI C serves to define what is meant by the term 'suitable antimicrobial preservative' in accordance with the relevant Notice in Part 2 of the General Notices.

3. If during development a fully quantitative, comparative evaluation of different preservative systems would be useful, the procedure described in the Appendix could be extended. For example, the incorporation of additional sample times would allow an estimation of microbial death rates.

4. The test is intended for application to those products that may support the growth or viability of microbial contaminants. It is based on the premise that preservatives are used primarily to protect products from in-use microbial contamination but also recognises their role in reducing the bioburden of 'non-sterile' products. In-use contamination is of relevance to multidose products, both sterile and non-sterile. Bioburden is of relevance to non-sterile products, both multidose and single dose.

5. The present European Pharmacopoeia text provides criteria for parenteral, ophthalmic, topical and oral preparations. The criteria for ear preparations are equivalent to those specified for topical preparations thus maintaining parity between these two types of product.

6. An unusual feature of the European Pharmacopoeia text is the inclusion of two sets of criteria (A and B) for parenteral and ophthalmic preparations and for topical preparations. The A criteria express the recommended efficacy to be achieved, that is, they represent generally applicable 'target' criteria.

7. It is recognised that for certain products, for example, some antacids and certain biological products, these target criteria are unlikely to be achieved except at the expense of some other property of equal or greater importance. The alternative criteria to be met in these circumstances are a matter for agreement between the manufacturer and the competent authority and should take account of any special considerations relevant to the specific product. The B criteria for parenteral and ophthalmic products and for topical products were adopted by the European Pharmacopoeia Commission in deference to those member states that wanted published guidance on the minimum values below which any alternative criteria should not fall.

8. As noted in paragraph 2 above, the pharmacopoeial test is intended to provide a framework within which to develop a test suitable for the particular product being examined. Detailed descriptions of all aspects of testing are therefore inappropriate within the pharmacopoeial test itself. The following Annex draws attention to some key features of the test and offers additional guidance on certain practical aspects of testing.

Annex

9. Several features have been identified as sources of procedural variation in the test that may contribute to variation in the outcome of the test. A clearly written and sufficiently detailed test protocol is therefore essential. Some of these features are discussed in this Annex.

10. **Test organisms; culture maintenance** Potential sources of variation to which attention should be given include the source, age and storage of the microbial culture and the number of passages between the freeze-dried strain collection culture (repository culture) and the suspension of organisms used to inoculate the product (the test suspension). It is recommended that the repository culture is cultured and aliquots freeze-dried or stored under liquid nitrogen. It is also recommended that the sub-culture used as the test suspension should be no more than 5 passages from the repository culture.

11. **Product inoculation** Potential sources of variation to which attention should be given include the culture media and method used to prepare the inoculum, the inoculum: product ratio and the homogeneity of the inoculum–product mixture. Appendix XVI C states that the test suspension shall be used immediately. It is recommended that this is interpreted to mean that, once prepared, the test suspension should not be stored but may be used over a period of 8 hours provided that it is kept at a temperature of 2° to 8°.

12. **Test container** It is emphasised that, as indicated in the Appendix, wherever possible, the product should be inoculated and incubated in its original container (market pack). Where, however, it is necessary to transfer the product to some other container, for example, in order to achieve

homogeneous distribution of the inoculum, careful consideration needs to be given to the choice of test container. Features of such a container that will influence its suitability as a test container include the material from which it is made, its shape and size (volume) and the type of closure. The material from which the container is made should not affect the product, for example, by leaching or by sorption of ingredients. Particular attention should be paid to possible changes in product pH since these can markedly affect preservative activity. A container with smooth surfaces and a wide neck that will allow ease of access and mixing is recommended for creams and other viscous preparations.

13. **Test procedure** Test conditions such as storage temperatures and sample times are given in Appendix XVI C. Working at a temperature within the stated range of 20° to 25°, it is advisable, wherever possible, to minimise the temperature difference from test to test.

14. **Counting survivors** The Appendix specifies that the count obtained for the inoculum is used as the baseline for calculating the reduction in viable micro-organisms.

15. **Preservative inactivation** When residual antimicrobial activity is removed either by the use of an inactivating agent or by dilution, it is necessary to confirm the ability of the system to support the growth of the test organisms by the use of appropriate controls. These controls should simulate test conditions and allow validation of the counts. In designing such controls an appropriate target recovery efficiency, for example 70% recovery, should be set.

16. **Interpretation of results** Where a test criterion is given as 'no increase' this is intended to be interpreted as no increase above the counts obtained at the previous specified sample time. It is expected that, having achieved the required reduction in counts at the shorter time interval specified, the preservative will maintain the microbial population at or below this lower level.

K. Stereochemistry

This section describes the way in which the stereochemistry of a substance is indicated in the chemical definitions and graphic formulae of the British Pharmacopoeia and the way it may be identified and/or controlled within the tests in a monograph.

1. Many medicinal substances that contain one or more chiral centres and that are already on the market have been made available for pharmaceutical use as racemic mixtures with little known about the biological activities of the separate isomers. This has been reflected in the monograph in the Pharmacopoeia and a test to show that the substance is the racemic mixture has not usually been included unless it was known that at least one of the separate enantiomers was also available commercially. Nevertheless, with increasing concern by regulatory authorities for substances to be made available as single isomers, tests for enantiomeric composition will become more common (see section on tests below).

Chemical definition

(monographs other than those of the European Pharmacopoeia)

2. In the case of substances containing a single chiral centre, the descriptor '(*RS*)-' is included at the appropriate position in the chemical definition of the substance to indicate a racemic mixture.

3. For substances containing multiple chiral centres and comprising a mixture of all possible stereoisomers the term '*all-rac*-' has been used, for example Isoaminile. In those few substances existing as diastereoisomeric mixtures, that is where in one or more centres the stereochemistry is explicit but in other centres it is not, each centre is defined either as the specific (*R*)- or (*S*)- configuration, or as racemic (*RS*)-, respectively.

Graphic formulae

4. When a medicinal substance is a racemate, an indication is given by means of the graphic formula.

5. Because in graphic formulae there is no generally accepted convention for depicting a racemate, each racemic substance with one chiral centre is shown in the (*R*)- form with the appended text 'and enantiomer' for example, Carteolol Hydrochloride. For the *all-rac*- mixtures, such as Docusate Sodium and Alpha Tocopheryl Acetate, non-stereospecific graphic formulae are drawn and the legend 'mixture of *n* stereoisomers' added beneath (where *n* is the number of possible stereoisomers); the stereogenic carbon atoms concerned are identified by means of asterisks.

6. In diastereoisomeric mixtures, the unique configuration centres are drawn as such, while each racemic centre (with equal amounts of the (*R*) and (*S*) configuration) are indictated by an asterisk and the legend 'racemic at C*' appended. For example, Carbenicillin Sodium is drawn in this way; the chiral atoms in the penicillanic acid ring each in their single specific configuration and the phenylmalonyl side-chain chiral atom marked with an asterisk.

Tests

7. In future, when a monograph describes an enantiomer, it will include both a test for specific optical rotation under Identification and a test, using methods such as chiral chromatography, to control enantiomeric purity.

8. When both the racemic mixture and the enantiomer are available, the monograph for the racemic mixture will, where appropriate, specify a test for angle of rotation together with a cross reference under Identification. The test for angle of rotation will normally specify low, symmetrical limits about zero where this has been shown to limit the presence of optically active impurities and demonstrate approximately equal proportions of the enantiomers.

9. When only the racemic mixture is available, the monograph for the racemic mixture may, where appropriate, specify a test for angle of rotation.

L. Microbiological Assay of Antibiotics

This section provides guidance on interpretation of statements in the Pharmacopoeia concerning content limits for those antibiotics and their preparations for which the monograph specifies a microbiological assay.

1. The statements in the Pharmacopoeia concerning the potency of antibiotics are framed to provide a control analyst with the means whereby he can ascertain whether or not the material or preparation in question is satisfactory, that is, they provide criteria appropriate to a 'check assay'.

2. In order to be confident that, when assayed by a control analyst, a material or preparation would meet the pharmacopoeial criteria a manufacturer would himself need to work to criteria appropriate to a 'release assay'.

3. The need for different criteria for check and release assay purposes arises from the inherent variability of biological systems which precludes assigning an exact value to the true potency. It is possible only to give a range of values within which the true potency can be expected to lie with a defined

degree of confidence (95%; $P = 0.95$ for pharmacopoeial purposes). In such circumstances the fiducial limits of error computed for the assay in question define the lower and upper limits within which the true potency of the sample lies, with a probability of 95%.

4. The required minimum precision for an acceptable assay of any particular antibiotic or preparation is defined in the appropriate monograph in the paragraph entitled Assay. This degree of precision is the minimum acceptable for determining that the final product complies with the official requirements. It may be inadequate for a decision about the potency that should be stated on the label or used as the basis for calculating the quantity of an antibiotic to be incorporated in a preparation. In such circumstances, assays of greater precision may be desirable with, for instance, fiducial limits of error of the order of 98 to 102%. With this degree of precision, the lower fiducial limit lies close to the estimated potency. By using this limit, instead of the estimated potency, to assign a potency to the antibiotic either for labelling or for calculating the quantity to be included in a preparation, there is less likelihood of the final preparation subsequently failing to comply with the official requirements for potency. Greater precision can be achieved by statistically combining the results of two or more independent assays.

Bulk antibiotic

5. In a monograph for a bulk antibiotic a minimum potency in IU is given under the heading Definition and this is to be interpreted in accordance with the second paragraph of the General Notice on Biological Assays and Tests. This states that 'The material is not of pharmacopoeial quality if the upper fiducial limit of error is less than the stated potency. For such antibiotics the required precision of the assay is stated in terms of the fiducial limits about the estimated potency.'

6. Taking Amphotericin, the monograph for which has a defined minimum potency of not less than 750 IU per mg, as an example of a bulk antibiotic: a control analyst would judge the material *unsatisfactory* with respect to potency only if the *upper* fiducial limit of error [UFLE] obtained in his assay was *less* than 750 IU per mg, calculated with reference to the dried substance. A manufacturer, on the other hand, would consider suitable for release only those batches for which the *lower* fiducial limit of error [LFLE] obtained in his assay was *greater* than 750 IU per mg, calculated with reference to the dried substance.

Bulk antibiotic (Fig. SC1L-1)

Probability = 0.95,

Precision = 95–105%

Let X be the monograph value for the minimum potency of the bulk antibiotic [750 IU per mg, for example, for Amphotericin].

Let R_1, R_2, R_3 be the estimated potency found by the manufacturer in the release assay.

To ensure (with 95% confidence) that the true potency of his bulk substance is not less than the desired minimum [*ie* that R not <X], the manufacturer releases only a batch such as R_1 for which the lower fiducial limit of error of the estimated potency is ≥X; he rejects batches such as R_2 and R_3 for which the lower fiducial limit of error is <X.

Let C_1, C_2, C_3, C_4 be the estimated potency found by the control analyst in the check assay.

Only when the upper fiducial limit of error of the estimated potency is <X can the control analyst conclude (with 95% confidence) that the true potency of the sample being examined is less than the desired minimum value. He would fail a batch with estimated potency C_4.

Formulated preparation

7. In a monograph for a formulated preparation the lower and upper limits of content are given under the heading Assay and are given as the values (stated in terms of percentage of labelled claim) within which the fiducial limits of error of the estimated potency obtained in the Assay must lie.

8. For a formulated preparation the results of the Assay and the content, or strength, stated on the label are given in terms of IU unless specific instruction to calculate a 'weight equivalent' is given as, for example, in the monograph for Streptomycin Injection. Such a 'weight equivalent' cannot be given for certain antibiotics, in particular those like Neomycin Sulfate which consist of a variable mixture of components.

9. Taking Neomycin Eye Ointment, the monograph for which requires the upper fiducial limit of error to be not less than 90% and the lower fiducial limit of error to be not more than 115% of the stated amount, as an example of a formulated preparation: a control analyst would judge a product *unsatisfactory* with respect to content only if the *upper* fiducial limit of error obtained in the check assay was *less* than 90% or if the *lower* fiducial limit of error was *greater* than 115% of the amount expected in accordance with the strength stated on the label. A manufacturer, on the other hand, would consider suitable for release only those batches of the product for which the *lower* fiducial limit of error obtained in his assay was *greater* than 90% and for which the *upper* fiducial limit of error was *less* than 115% of the amount expected in accordance with the strength stated on the label.

Formulated preparation (Fig. SC1L-2)

Probability = 0.95,

Precision = 95 – 105%

Let Y be the stated content/strength [labelled claim] of the preparation [3500 IU per g of ointment, for example, for Neomycin Eye Ointment].

Let R_1, R_2, R_3, R_4, R_5 be the estimated content/strength found by the manufacturer in the release assay.

To ensure (with 95% confidence) that the true content/strength is not less than the specified minimum [*ie* that R not <90% Y], the manufacturer releases only batches such as R_1 and R_2 for which the lower fiducial limit of error of the estimated potency is ≥90% Y; he rejects batches such as R_3 and R_4 for which the lower fiducial limit of error is <90% Y. To ensure (with 95% confidence) that the true content/strength is not greater than the specified maximum [*ie* that R not > 115% Y], the manufacturer also rejects batches such as R_5 for which the upper fiducial limit of error is > 115% Y. In order to avoid possible problems of compliance with monograph assay limits at the end of shelf-life for those antibiotics where stability is an issue, manufacturers are advised to exercise caution in releasing batches such as R_2 for which the lower fiducial limit of error is less than the value stated on the label. The advice given in paragraph 4 may be of assistance in these circumstances.

Let C_1, C_2, C_3, C_4, C_5, C_6 be the estimated content/strength found by the control analyst in the check assay.

Only when the lower fiducial limit of error of the estimated content/strength is > 115% Y or when the upper fiducial limit of error of the estimated content/strength is <90% Y can the control analyst conclude (with 95% confidence) that the true content/strength is outside the specified range; he would fail batches with estimated content/strength C_4 and C_6.

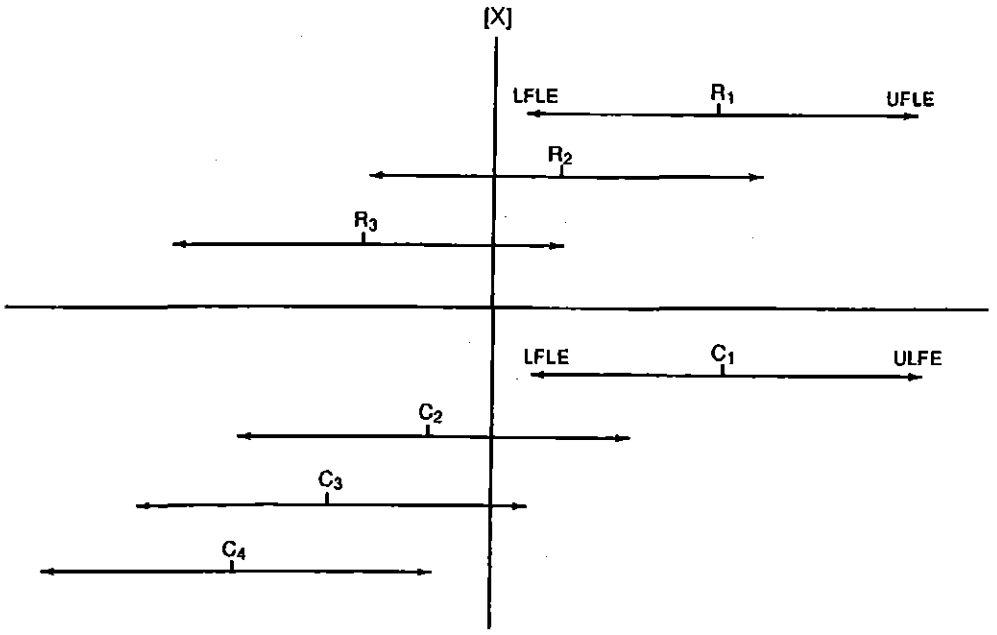

Fig. SC1L-1

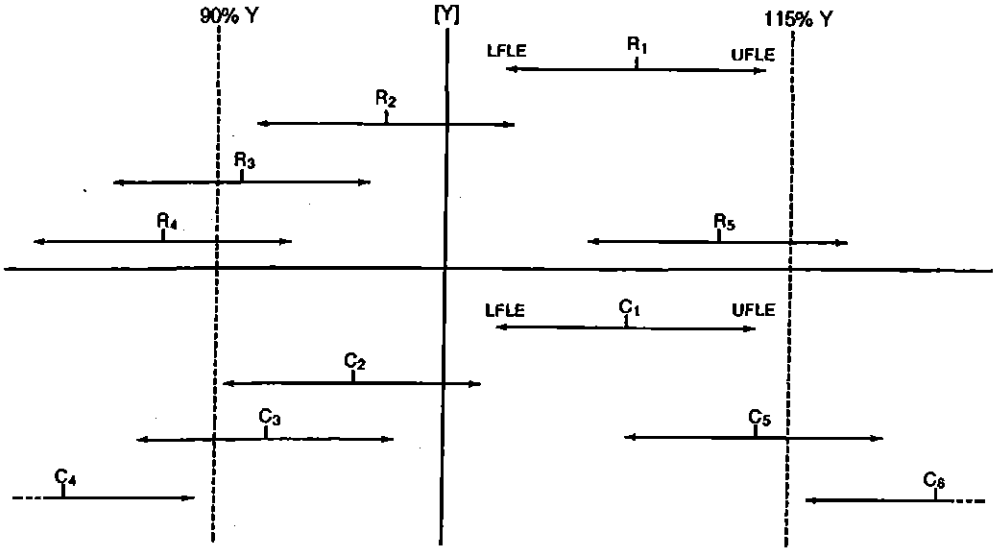

Fig. SC1L-2

It is important to recognise that, for the reasons explained in paragraph 3, a batch giving the estimate R_1 in a release assay may give the estimate C_4 in a check assay *without any change in the true potency*.

Definitions

Assay A single test carried out for the purpose of estimating the potency of a material/preparation or the pooled results of two or more such tests.

True potency The actual potency of the material/preparation at the time of assay. In practice this value can never be exactly evaluated.

Stated or labelled potency This is often a nominal value assigned to a formulated preparation from knowledge of the potency of the bulk material. In the case of bulk materials, it may be calculated from assay data.

Estimated potency The potency calculated from assay data. It is misleading to refer to a 'best estimate' [see under fiducial limits below].

Fiducial limits [confidence interval] These are limits to the true potency of the material/preparation and are calculated on the assumption that there is no bias in the assay system. They may be calculated for any desired level of probability; for pharmacopoeial purposes a level of 0.95 is applied. The concept is that, if the assay could be repeated many times, the true potency would lie within the fiducial limits in 95% of assays. Thus, in any particular assay, the true potency could be anywhere within the fiducial range (and occasionally outside it) and the estimated potency is no better measure of the true potency than any other value in the range.

Release and check assays A release assay is an assay carried out by those responsible for assigning a potency to a material or declaring a content or strength for a preparation [manufacturers]. A check assay is an assay carried out by those responsible for checking the potency of a material or the content or strength of a preparation [control authorities,

independent analysts and purchasers of bulk materials]. The use of these two terms does not imply a fundamental difference in the design or execution of an assay but rather in the interpretation of the results obtained. A check assay only enables a control analyst to say unequivocally when a material/preparation is unsatisfactory [see illustration above].

M. Microbial Contamination

This section of Supplementary Chapter I provides information on the status and application of the texts on microbial contamination included in Appendix XVI. These texts, which are taken from the European Pharmacopoeia (Ph Eur), are used both to satisfy mandatory requirements of the Pharmacopoeia and as guidelines for the purposes of microbiological monitoring. This chapter provides clarification on the application and interpretation of the test methods and criteria in the different situations.

1. Appendix XVI B and Appendix XVI F comprise several sub-sections describing tests for detecting different types of microbial contamination and Appendix XVI D and Appendix XVI G provide guidance on the microbial quality of pharmaceutical preparations and herbal medicinal products.

2. The tests for *specified micro-organisms*, included as Appendix XVI B1, are those included as method 2.6.13 of the Ph Eur. These tests describe the methods used to set mandatory requirements in monographs for certain bulk materials of natural origin. For example, the monograph for Dried Aluminium Hydroxide specifies the absence of *Escherichia coli* and from bile-tolerant gram-negative bacteria and that for Pancreatin specifies 1 g is free from *Escherichia coli* and 10 g is free from Salmonella. These methods are also used to support the relevant non-mandatory recommendations made within the guidelines on the microbiological quality of pharmaceutical preparations and herbal medicinal products (see paragraph 9 below).

3. The tests for *total viable aerobic count*, included as Appendix XVI B2, are those included as method 2.6.12 of the Ph Eur. These quantitative tests are used in two contexts within the Ph Eur. In addition to being invoked to set mandatory limits for a range of bulk materials of natural origin, the methods are also used to support the non-mandatory guidelines on the quality of pharmaceutical preparations and herbal medicinal products (see paragraph 9 below).

4. In Appendix XVI B2 of the British Pharmacopoeia (BP), an introductory paragraph states that the tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. For example, the monographs for Agar and for Dried Aluminium Hydroxide specify total aerobic microbial counts of not more than 10^3 micro-organisms per gram and total combined yeast/mould counts of not more than 10^2 micro-organisms per gram. The method indicates that, when used for such purposes, it is to be carried out in accordance with the instructions in the general text, including the number of samples to be taken, and the results are to be interpreted as stated.

5. When the tests are used by a manufacturer for monitoring raw materials and/or finished products or for process validation, the sampling plans for microbiological examination and the method of interpretation of the results are matters for agreement between the manufacturer and the competent authority. (See also Basis of Pharmacopoeial Requirements in the Introduction to Supplementary Chapter I.)

6. The *test for absence of mycoplasmas*, included as Appendix XVI B3, is method 2.6.7 of the Ph Eur as applied to vaccines for human use. This test is invoked as a mandatory requirement in the relevant parts of the Production section of certain monographs for viral vaccines produced in cell cultures or in eggs, for example, Inactivated Influenza Vaccine (Surface Antigen). (The test as applied to veterinary vaccines is reproduced in the BP (Veterinary).)

7. The *test for mycobacteria*, included as Appendix XVI B4, is method 2.6.2 of the Ph Eur. Reference to this method is made under the tests for extraneous agents in viral vaccines (see paragraph 8 below).

8. The *tests for extraneous agents in viral vaccines*, included as Appendix XVI B5, are those included as method 2.6.16 of the Ph Eur. These tests are invoked as mandatory requirements in the relevant parts of the Production section of certain monographs for viral vaccines.

9. As indicated in the general monograph for Pharmaceutical preparations, recommendations on the microbiological quality of non-sterile pharmaceutical preparations are provided in Appendix XVI D and Appendix XVI G of the BP.

The text on *Microbiological Quality of Non-sterile Pharmaceutical Preparations*, included as Appendix XVI D, is general text 5.1.4 of the Ph Eur. As described in the General Notices: 'General chapters become mandatory when referred to in a monograph, unless such reference is made in a way that indicates that it is not the intention to make the text referred to mandatory but rather to cite it for information'. Where general text 5.1.4 is referred to in a general monograph as giving recommendations on microbiological quality, different acceptance criteria may be justified.

The general monograph for Oral Liquids, for example, has a mandatory Production requirement that 'In the manufacture, packaging, storage and distribution of liquid preparations for oral use, suitable measures are taken to ensure their microbial quality' the following statement 'recommendations on this aspect are provided in the text on *Microbial Quality of Pharmaceutical Preparations (5.1.4)*' clearly constitutes a non-mandatory recommendation.

The text on *Microbiological Quality of Herbal Medicinal Products for Oral Use*, included as Appendix XVI G, is general text 5.1.8 of the Ph Eur. This text is described as 'recommended acceptance criteria for microbiological quality of herbal medicinal products'.

10. The texts of Appendix XVI D and Appendix XVI G are intended to provide guidance to those concerned with this important aspect of quality assurance of final dosage forms and herbal medicinal products for oral use. The advisory limits for products in both texts should be used by manufacturers for process validation and may be used as part of a general microbial monitoring programme to identify needs for corrective action. The availability of authoritative guidelines provides a useful yardstick for official control laboratories when conducting surveys of products on the market. It is emphasised that the inclusion of advisory limits in the Pharmacopoeia is not intended to imply the need for end-product microbiological testing on a batch-to-batch basis. Such testing would be inconsistent with the principles of good manufacturing practice and the analytical burden imposed by such testing could not be justified for the majority of products.

N. Particulate Contamination

This section of Supplementary Chapter I provides information on the status and application of the texts on particulate contamination included in Appendix XIII. Guidance is also offered on limits for visible particles in small-volume injections.

1. Appendix XIII comprises two methods for determining particulate contamination:- Sub-visible particles and Visible particles. Of these two methods, only that for sub-visible particles is currently invoked as a mandatory requirement within the monographs of the Pharmacopoeia.

2. The test for **sub-visible particles** included as Appendix XIII A is method text 2.9.19 of the European Pharmacopoeia. The criteria are invoked by means of the revised Ph Eur general monograph for Parenteral Preparations. The statements previously included in certain individual monographs of the British Pharmacopoeia such as Sodium Chloride Intravenous Infusion have therefore been deleted and reliance placed on the general monograph.

3. The test for **visible particles** included as Appendix XIII B is method text 2.9.20 of the European Pharmacopoeia. This text describes standardised viewing conditions but sets no criteria of acceptance. Contamination by visible particles is governed instead by the requirement of the Ph Eur general monograph for Parenteral Preparations that injections and intravenous infusions that are solutions are required to be 'clear and practically free from particles'. It is recognised that this latter requirement can give rise to problems of interpretation. These problems could, perhaps, be overcome by providing simple criteria for the test for visible particles suitable for application as a pharmacopoeial 'check-test', that is, for application by an independent analyst, for example, a hospital quality control pharmacist, as a means of judging the quality of a particular parenteral preparation.

4. The need to set limits is based on the premise that an expectation of total absence of visible particles from all containers from a batch of an injectable preparation is unreasonable and unrealistic. An attributes-based test using a small sample together with simple pass/fail criteria would be consistent with the needs and constraints of a check test. The criteria chosen would need to be capable of detecting a batch that was grossly contaminated while representing an acceptably low chance of condemning batches of satisfactory quality through a small sample being unrepresentative. It would, of course, be unlikely that, if a sample failed such a test, consequent action would be initiated by the competent authority on the result of a single test. In such circumstances the competent authority would investigate the occurrence further with the manufacturer.

5. The following criteria are offered as generally suitable for a check test for small volume injections that are solutions. For guidance, it is suggested that in total 20 containers are examined as described in Appendix XIII B and any particles recorded. It is suggested that the preparation being examined should be considered to have failed the test if one or more particles are found in more than one container.

6. It is emphasised that these criteria are not intended for use by a manufacturer for batch release purposes. It is expected that a manufacturer would obtain assurance of the quality of his product with respect to visible particulate matter by 100% inspection or by other appropriate means in accordance with good pharmaceutical manufacturing practice (GMP).

5.17.2. Recommendations on Testing of Particulate Contamination: Visible Particles

(Ph. Eur. general text 5.17.2)

This general chapter is non-mandatory; it provides information on visible particle testing of liquid preparations that refer to general chapter 2.9.20. Particulate contamination: visible particles in their monographs. This information represents considerations used in the field of visual inspection and in the control of visible particles in medicinal products. This chapter is not intended to elaborate on good manufacturing practice requirements, but should be read in conjunction with such requirements.

INTRODUCTION

Particulate contamination in liquid preparations consists of mobile, undissolved particles, other than gas bubbles, that are unintentionally present. Particulate contamination may originate from various sources and is to be minimised independent of its type. The level of particulate contamination in preparations must be controlled. Depending on the size of the particles, particulate contamination may be in the visible or the sub-visible size range. In products such as parenteral preparations, although there is little supporting evidence generated by clinical studies, visible particles are considered to be a potential safety concern, and their presence should therefore be minimised as far as possible in any product intended for parenteral administration to humans or animals. As visible particles can be assumed to be heterogeneous and non-uniformly distributed across a given product batch, it is important to use sufficiently large sample sizes. Whilst the presence of such particles in general is random, it can nonetheless be a sign of a systematic issue; the occurrence of particles must therefore be assessed and appropriate measures taken to eliminate any source of particulate contamination and/or improve the formulation, primary packaging or manufacturing process, as required.

Particles may be extrinsic (deriving from the environment, equipment, primary packaging or personnel) or intrinsic (related to the formulation, including active substances and excipients, process residuals or contaminants, or resulting from interactions between the formulation and primary packaging). Examples of extrinsic particles include cellulose fibres, glass, paint flakes, hair and insect parts. Examples of intrinsic particles include proteinaceous particles, silicone droplets, inorganic precipitates such as barium sulfate or aluminium sulfate, fatty acid particles from the degradation of polysorbates, and glass lamellae. It is sometimes only possible to detect particles during storage, i.e. during stability studies on the product, hence the importance of particulate contamination monitoring using appropriate test methods, such as that described in general chapter *2.9.20* for visible particles or those described in general chapter *2.9.19* for sub-visible particles. The assessment of particles should be based on the safety considerations related to the product and the route of administration.

In some cases, for example in cell therapy medicinal products or dispersions, particles may be the active substance itself and be intentionally present. However, with the exception of these cases, visible particles of any kind are unwanted in medicinal products, including biotechnology-derived products, and effort must be made to avoid or at least minimise their presence.

Additionally, it is recommended that end-users check for visible particles before administering the medicinal product.

VISUAL INSPECTION: GENERAL CONSIDERATIONS

The intrinsic characteristics of some medicinal products may render visual inspection for particles difficult. This is the case, for example, for opalescent (turbid) solutions or dispersions, coloured solutions or lyophilisates, opaque or coloured containers, and parenteral preparations such as suspensions and cell therapy products in which particles are naturally present. Measures must be taken to ensure that visual inspection operators are able to detect particulate matter during a 100 per cent inspection of a batch followed by an acceptable quality level (AQL) or equivalent sampling plan method and subsequent visual inspection within quality control testing. One such measure is the use of defect sets that are representative of the product and contain a variety of potential visible particle defects together with negative and positive controls. Operators must also receive in-depth training using performance limits for defect detection and unjustified rejects. Non-destructive measures to improve inspection techniques may also be required, for example the use of a light intensity higher than 3750 lux, inspection of each container for more than 5 s and against both black and white backgrounds. Destructive measures are used only for quality control purposes, for example dilution of the product with visible-particle-free water or another suitable diluent. In addition, when the container hampers inspection, it may be necessary to transfer the contents to a suitable clear container.

VISUAL INSPECTION DURING PRODUCTION

INSPECTION SCHEMES

Each container of a liquid preparation (e.g. vial, syringe, ampoule) is visually inspected after filling and closure. During this 100 per cent inspection, containers in which any particulates are observed are removed (culled) from the batch and rejected. An additional spot check is also often performed according to a sampling plan based on a pre-defined AQL; the sample size and the acceptance number can be deduced using the tables included in ISO 2859-1 or by other statistical means. The AQL confirms the suitability of the inspection to ensure an acceptable quality level.

Suitable AQL limits for defect categories (e.g. minor, major or critical defect) must be defined. The presence of visible particles in a container is classified as at least a 'major defect'. An investigation is usually triggered if the AQL limit is exceeded or if atypical particles are detected.

ASPECTS TO CONSIDER

During the 100 per cent inspection, visual inspection for particles is performed according to the method provided in general chapter *2.9.20.* This process can be manual or, if adequately validated against the manual inspection method, semi-automated or fully automated. Validation of automated or semi-automated methods against manual visual inspection typically comprises evaluation of rejected units against predefined acceptance criteria, including the false reject rate, using representative samples and defect sets. The defect set used for qualification of inspection operators should contain a range of defects, including units presenting typical particulate contamination, as mentioned above. The defect set itself should be appropriately stable over the intended period of use.

Typically, operators are unable, by visual inspection alone, to classify particulates into different categories and materials, and thus allow root-cause analysis.

The detection of visible particles is probabilistic by nature and depends on various factors such as: light intensity; inspection conditions; use and type of magnification; observation time; inspection background; distance from samples; type and speed of rotation; fill volume; primary packaging material, size and type; operator and equipment capability; and the size, number, type and refractive index of particles. Consequently, whilst the goal of a 100 per cent inspection followed by AQL testing is to eliminate all containers containing any visible particles, some of these may escape detection due to poor detectability and visibility. Every visual inspection system is therefore characterised by an accepted statistical probability to detect units with visible particles and an accepted statistical probability to miss units with visible particles. All containers found to contain visible particles or presenting any defects considered as unacceptable are excluded from the acceptable part of the batch, unless otherwise authorised or justified. In the case of freeze-dried products undergoing 100 per cent inspection followed by AQL testing, only the visible part of the cake and the primary packaging components can be examined. Particles originally present in the solution may become embedded in the cake during manufacture and remain undetected.

VISUAL INSPECTION FOR QUALITY CONTROL

Visible particle inspection for quality control is also conducted as described in general chapter *2.9.20.* This inspection is typically performed manually.

ASPECTS TO CONSIDER

Visual inspection for quality control is performed on either liquid products or reconstituted solutions of dried products such as lyophilisates. Inspection of visible particles in freeze-dried products is performed as part of quality control testing for batch release using destructive methods. Whereas the 100 per cent visual inspection and AQL testing are carried out on sample units without further preparation (e.g. reconstitution), samples of freeze-dried product for quality control testing are reconstituted under conditions simulating those of actual use by the patient or healthcare professional. In order to avoid potential contamination with particles, sample preparation for quality control testing should be conducted under appropriate conditions. Sample sizes should be determined based on statistical considerations, for example special sampling plans for destructive testing in ISO 2859-1.

Testing single units only is not recommended. However, the sample size available for quality control may be limited due to the size of the batches and other considerations, for instance in the case of biological products. In general practice, a sample size of 10-20 units is common.

Visible particle requirements are applicable until the product reaches the end of its shelf-life. Thus, quality control testing for visible particles should be performed regularly during long-term stability studies and preferably also during accelerated degradation studies. The emphasis is on stability-indicating attributes such as precipitation, agglomeration, discouloration and glass from delamination, and not on potential extrinsic particle contaminants. Any particles observed during stability testing that are considered indicative of a systematic issue, rather than single particles found in stability studies, should be identified to assess their possible root-cause and define suitable corrective actions.
If investigation confirms a systematic issue, such as protein particles due to the formulation or glass from delamination, the formulation, primary packaging or manufacturing process of the medicinal product should be addressed to mitigate the occurrence of particles, unless otherwise authorised or justified.

ACCEPTANCE CRITERIA

An additional quality control test for visible particles (e.g. for batch release testing) may be omitted for liquid preparations subjected to 100 per cent visual inspection followed by AQL testing. A successful AQL inspection indicates that the batch complies with the requirement 'practically free from visible particles'. However, destructive quality control testing cannot be avoided for lyophilisates, since it is performed on the reconstituted product, whereas both the 100 per cent visual examination and AQL testing are carried out on the dried material.

Quality control acceptance criteria often refer to the occurrence of visible particles per unit, across the number of samples analysed. For example, a few small particles in 1 unit out of a set of 10-20 samples analysed may not be of any significant concern. Significant amounts of particles in a single unit would, however, be a concern.

Establishing acceptance criteria for visible particles in single units is a difficult task and it is unreasonable to expect numerical values to be set. Whilst 'zero particles' remains the goal, it is not considered to be a realistic quality control acceptance criterion since the probabilistic nature and random occurrence of visible particles often leads to the discovery of single particles in single units. Appropriate approaches must be defined for each product. A universal recommendation is not suggested.

'Practically free from visible particles' reflects the capability of the manufacturing and testing process. The term is applicable at the batch level of a medicinal product, not for single units examined individually. However unrealistic, a 'zero particles' product is nonetheless a worthy goal.

Products administered using a filter

With some parenteral products, for example products for which there is insufficient product knowledge, filters may be used to reduce the risks related to particles that may form during storage. However, the use of such filters does not constitute acceptance of particles after manufacture or allow particulate contamination *per se*. If justified and authorised, products administered using a filter can be exempt from the 'practically free from particles' requirement, providing it has been demonstrated that the filter delivers a filtrate that complies.

O. Inhaled Products

Formulated Preparations: Specific Monographs

The following policy applies to BP monographs for inhaled products. BP monographs contribute to the safety and efficacy of inhaled products through the provision of quality specifications in line with current best practices and test methodology.

1. Alignment of BP terminology and test methodology with those used in the European Pharmacopoeia (Ph. Eur.)

a. Titles for BP monographs for inhaled products should use the relevant European Directorate for the Quality of Medicines and Healthcare (EDQM) full Standard Term for the dosage form, with the BP legacy title included as a subsidiary title for revised monographs.

b. The requirements should be consistent with those specified in the Ph. Eur.

2. Alignment of BP monographs for inhaled products with the Ph. Eur. general monographs for Preparations for Inhalation and Pharmaceutical Preparations.

a. Fine Particle Dose No tests for Fine Particle Dose tests will be included for specific BP finished inhaled product monographs under this revised policy, but a Production statement indicating that a test and limits should be agreed with the competent authority will be included in line with the Preparations for Inhalation General Monograph (with the exception of nebuliser preparations).

b. Uniformity of delivered dose The Uniformity of delivered dose test should be aligned with the Ph. Eur. General Monograph for Preparations for Inhalation and should be included in BP monographs for inhaled products with the exception of preparations intended for nebulisation.

c. Uniformity requirements for nebuliser preparations Appropriate Uniformity of content tests should be included in BP finished product monographs for preparations intended for nebulisation, to harmonise with the specifications of available products.

d. Assay An appropriate Assay (content of active requirement) for all BP monographs for inhaled product monographs is required. The type of Assay included in the monograph should follow the approach taken by the innovator product and the other established products in order to ensure a consistent approach. This is particularly important for preparations that are not intended for nebulisation. Where the average of the results of the Uniformity of delivered dose are used as an Assay, the content limits should be aligned with the Preparations for Inhalation general monograph, to harmonise with the specifications of licensed products.

3. Preparations for Inhalation of the British Pharmacopoeia This general monograph will be omitted for a future BP publication and suitable validated alternative methodology for the Content of active ingredient on actuation of the valve test will be established for existing product monographs when available. The Content of active ingredient on actuation of the valve test methodology from this general monograph will be moved to an Appendix and a cross-reference to this Appendix will be included in finished product monographs until alternative Assay methodology becomes available.

4. Water If control of water content has been shown to be important during product development, a requirement to determine water content should be included in a Production statement in BP monographs for inhaled products, which are not intended for nebulisation, to harmonise with the methodology and specifications used for established products.

5. Labelling With the exception of nebuliser preparations, where appropriate, Labelling statements should be added to BP monographs for finished inhaled products to reflect the label claim of the licensed products in terms of either the pre-metered dose, the metered dose or the delivered dose, as appropriate.

6. Inhalation Powder, Pre-Metered Where the expression *"the pre-metered unit is loaded into a dry-powder inhaler to generate an aerosol"* appears in individual BP monographs for Inhalation Powders, Pre-Metered, the term *"pre-metered unit"* refers to the single-dose pre-metered dosage unit, consisting of one or more powders of (a) solid active substance(s), presented in a suitable pharmaceutical form other than a hard capsule. The pre-metered unit is loaded into a dry powder inhaler to generate an aerosol.

Supplementary Chapter II

Names of Medicinal Substances and Preparations

This Supplementary Chapter provides information on Pharmacopoeial monograph titles, on the construction of titles for formulated preparations and on the structures and nomenclature of substances of natural or semi-synthetic origin.

Introduction

British Approved Names are devised or selected by the British Pharmacopoeia Commission and published by the Health Ministers on the recommendation of the Commission on Human Medicines. British Approved Names [BANs] are nonproprietary names established *inter alia* to provide suitable titles for monographs for medicinal substances in the Pharmacopoeia. The issue of a British Approved Name, however, does not imply that the substance will necessarily be included in the Pharmacopoeia. The guiding principles that are used in devising or selecting new British Approved Names are stated in the current edition of the British Approved Names book.

Where a Recommended International Nonproprietary Name [rINN] has been established by the World Health Organization, this name is now invariably adopted as the BAN and used as the title of the monograph, if any, in the Pharmacopoeia. In the past there were occasional differences between the rINN and the corresponding BAN. Many, but not all, of these differences were minor changes in spelling to accommodate normal English pronunciation and usage. Implementation of Directive 92/27/EEC, however, requires the use of rINN in the labelling of medicinal products throughout the member states of the European Community. In consequence, the relevant BANs have been modified to accord with the English version of the rINN. These changes were made by means of Supplement No. 4 to *British Approved Names 1997* and were reflected, where relevant, in the titles of the monographs in the 1998 edition and subsequent editions of the Pharmacopoeia as described in section A of this chapter.

The titles of monographs for medicinal preparations combine the British Approved Name with an appropriate term for the dosage form in question as described in section B of this chapter.

A. Changes in Monograph Titles

1. Certain changes in monograph titles were made in the British Pharmacopoeia 1998 in order to bring the titles in the British Pharmacopoeia in line with the names (recommended International Nonproprietary Names [rINNs]) that manufacturers were required to use on product labels and leaflets in accordance with EC Directive 92/27/EEC. The changed monograph titles remain in line with the rINNs manufacturers are required to use on product labels and leaflets in accordance with the Human Medicines Regulations 2012, as amended.

2. Normal practice within the British Pharmacopoeia when changing the title of a monograph is to retain the former title as a subsidiary title for a period of at least five years. This was not possible for these changes since use of the former name would no longer be permitted on product labels, *etc.* In order to provide continuity, a statement was therefore included in all affected monographs in the British Pharmacopoeia 1998 in the form 'When [former title] is prescribed or demanded, [current title] shall be dispensed or supplied.'. These statements were deleted from the British Pharmacopoeia 2003.

3. For substances for which there was a rINN, it was necessary to omit any subsidiary titles from the British Pharmacopoeia 1998. For example, the 'Vitamin C' subsidiary titles were omitted from the monographs for Ascorbic Acid, Ascorbic Acid Injection and Ascorbic Acid Tablets. Statements of the type described above (incorporating the name used in the former subsidiary title) were included and have been retained in subsequent editions, where appropriate, to provide continuity.

4. With the exception of Adrenaline and Noradrenaline, the practice of 'dual-labelling' (two names presented on separate lines) was discontinued in the British Pharmacopoeia 2003. In order to comply with EC Directive 92/27/EEC, the titles of all such affected monographs were replaced by the rINNs. A statement in the form '*The name [former title] was formerly used in the United Kingdom*' was included in all affected monographs in the British Pharmacopoeia 2003 and subsequent publications. These statements were deleted from the British Pharmacopoeia 2009.

5. Adrenaline and Noradrenaline are the terms used in the titles of monographs in the European Pharmacopoeia and are thus the official names in use in the Member States party to the Convention on the Elaboration of a European Pharmacopoeia.

B. Monograph Titles for Formulated Preparations

1. The titles of monographs for formulated preparations combine the appropriate drug substance name and pharmaceutical form.

2. The drug substance name is a British Approved Name [BAN] which in general is also the recommended International Nonproprietary Name [rINN]. In cases where the drug substance name is a British Approved Name (Modified), the modifying term is omitted from the title for the formulated preparation except where there exist two or more formulations containing different forms (salts, hydrates etc.) of the drug substance. In such cases the modifying term is retained in the monograph title. Thus, for example, the title of the monograph for tablets containing Clonidine Hydrochloride is Clonidine Tablets since tablets containing clonidine are formulated only with the hydrochloride. The title of the monograph for tablets containing Isosorbide Dinitrate, on the other hand, is Isosorbide Dinitrate Tablets, since tablets formulated with the mononitrate are also available.

3. The terms for the pharmaceutical form are either (i) derived from the relevant General Monograph; or (ii) terms in established use in the UK.

4. When the pharmaceutical form is described as the term in established use in the UK, reference to the pharmaceutical form from the relevant General Monograph will be provided as a Subsidiary Title and incorporated into the Definition

section of the monograph. For Codeine Linctus, for example, the title of the monograph and therefore the nonproprietary name of the preparation remains as Codeine Linctus, but the monograph contains the subsidiary title 'Codeine Oral Solution' and the Definition states that 'Codeine Linctus is an *oral solution* containing ...'.

5. Standard Terms, as published by the Council of Europe, are to be used for describing the pharmaceutical form in the Summary of Product Characteristics (SmPC), Patient Information Leaflet (PIL) and labelling of medicinal products receiving a European Community authorisation. Member States may use different product names for national authorisations.

C. Structures and Nomenclature of Substances of Natural or Semi-synthetic Origin

These notes provide a guide to the semi-systematic chemical nomenclature of certain groups of natural and semi-synthetic products. The following literature should be consulted for further information.

1. The definitive rules of the International Union of Pure and Applied Chemistry (IUPAC) for organic substances are contained in *Nomenclature of Organic Chemistry*, Section A to F and H, Pergamon Press, Oxford, 1979.

2. The IUPAC rules for inorganic substances are given in *Nomenclature of Inorganic Chemistry*, Blackwells, Oxford, 1990.

3. *Biochemical Nomenclature and Related Documents*, The Biochemical Society for the International Union of Biochemistry (IUB), 2nd edn. London, 1992. The following topics are included.

Stereochemistry (Nomenclature of Organic Chemistry, Section E)

Natural products and related compounds (Nomenclature of Organic Chemistry, Section F)

Abbreviations and Symbols

Amino acids, peptides, peptide hormones and immunoglobulins

Steroids

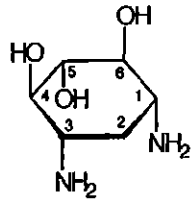
Carotenoids and tocopherols

Carbohydrates and cyclitols

Vitamins

A. Aminoglycoside Antibiotics

A.1 The aminoglycoside antibiotics are conveniently named by reference to 2-D-deoxystreptamine, **1**, in which name the configuration and numbering shown are implicit.



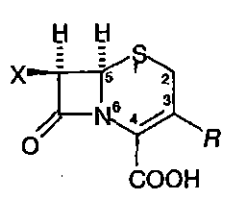
1

A.2 The aminoglycoside antibiotics commonly carry glycosyl radicals on the oxygen atoms attached to C-4 and C-6. The configuration and numbering shown in **1** should be strictly observed if confusion is to be avoided.

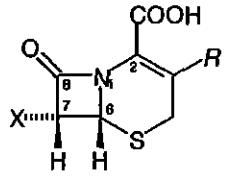
A.3 When one glycosyl radical is linked to another the names are separated by two locants which indicate the respective positions involved in this glycosidic union; these locants are enclosed in parentheses and separated by an arrow (pointing from the locant corresponding to the glycosyl carbon atom to the locant corresponding to the hydroxylic carbon atom involved).

B. Cephalosporin Antibiotics

B.1 The cephalosporin antibiotics are conveniently named by reference to either cephalosporanic acid (**2**, $R = CH_2OAc$, X = H) or cephem-4-carboxylic acid (**2**, R = X = H).



2



3

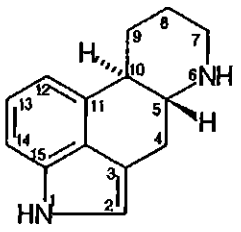
B.2 When names are based on cephalosporanic acid or cephem-carboxylic acid the traditional numbering shown in **2** is used.

B.3 Cephalosporanic acid is systematically named as (6*R*)-3-acetoxymethyl-8-oxo-5-thia-1-azabicyclo[4.2.0]oct-2-ene-2-carboxylic acid. Compounds that are named systematically use the numbering and orientation shown in **3**.

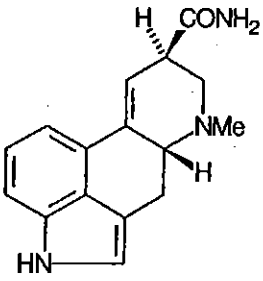
B.4 The cephalosporin antibiotics bear an acylamino group (X) at position 7 (under both numbering systems).

C. Ergot Alkaloids

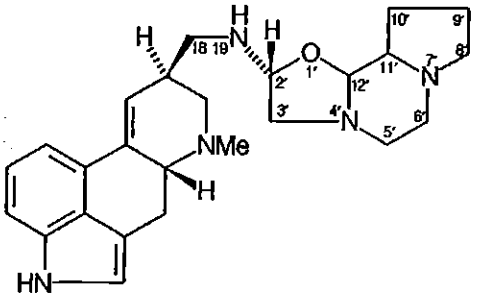
C.1 Members of the ergoline group of substances are conveniently named by reference to either ergoline itself, **4**, or to D-lysergamide, **5**. When names are so based the traditional numbering shown in **4** is used. In 9,10-dihydro compounds the configuration at position-10 needs to be specified.



4



5

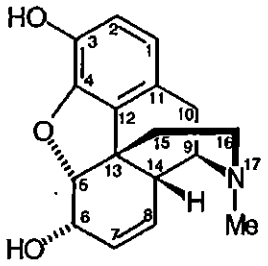


6

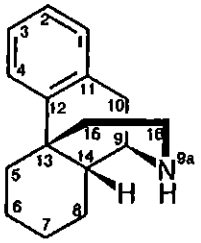
C.2 Members of the ergotamine group of substances are conveniently named by reference to ergotaman, **6**. Ergotamine itself is (5′*R*)-5′-benzyl-12′-hydroxy-2′-methyl-18-oxoergotaman-3′,6′-dione.

D. Morphines

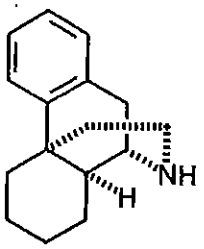
D.1 Members of the morphine and codeine group of substances have traditionally been named with reference to morphine itself, **7**, using the numbering shown. However, names may be based more conveniently on either morphinan, **8**, or *ent*-morphinan, **9**.



7



8



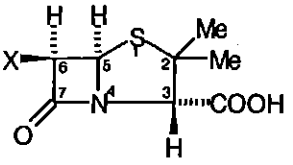
9

D.2 Morphine, **7**, is (5*R*, 6*S*)-4,5-epoxy-9a-methyl-7,8-didehydromorphinan-3,6-diol.

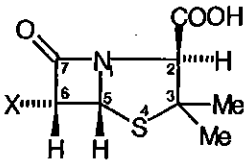
D.3 In certain morphine derivatives, an etheno or ethano bridge is present joining positions 6 and 14 and a hydroxyalkyl side chain is present at position 7.

E. Penicillin Antibiotics

E.1 The penicillin antibiotics are conveniently named by reference to penicillanic acid (**10**, X = H) when the classical numbering shown is used.



10



11

E.2 Penicillanic acid is systematically named as (2*S*, 5*R*)-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid. Compounds that are named systematically use the orientation and numbering shown in **11**.

E.3 The penicillin antibiotics are usually 6-acylamino penicillanic acid derivatives in which the configuration at position 6 is *R*.

F. Polypeptides

F.1 The following 3-letter and 1-letter symbols for amino acids, authorised by the IUPAC-IUB Joint Commission on Biochemical Nomenclature, are used for representing the sequences of polypeptides:

Alanine	Ala	A	*Leucine*	Leu	L
Arginine	Arg	R	*Lysine*	Lys	K
Asparagine	Asn	N	*Methionine*	Met	M
Aspartic Acid	Asp	D	*Phenylalanine*	Phe	F
Cysteine	Cys	C	*Proline*	Pro	P
Glutamine	Gln	Q	*Serine*	Ser	S
Glutamic acid	Glu	E	*Threonine*	Thr	T
Glycine	Gly	G	*Tryptophan*	Trp	W
Histidine	His	H	*Tyrosine*	Try	Y
Isoleucine	Ile	I	*Valine*	Val	V

F.2 The following symbols recommended by the Joint Commission are also used:

2-Aminohexanoic acid	Ahx
Sarcosine	Sar
Pyroglutamic acid	<Glu
tert-*Butoxycarbonyl*	Boc

F.3 When interpreting sequences of amino-acid residues, the hyphen should be considered as part of the symbol. Its use to separate the individual residues or radicals may be illustrated by the following example:

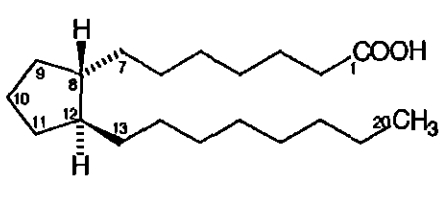
Gly	=	NH_2CH_2COOH
Gly-	=	$NH_2CH_2CO–$
-Gly	=	$–NHCH_2COOH$
-Gly-	=	$–NHCH_2CO–$
and thus,		
Gly-Gly-Gly	=	$NH_2CH_2CONHCH_2CONHCH_2COOH$

The residues are conventionally written with the amino group to the left and the carboxyl group to the right. This is implicit in the symbolism.

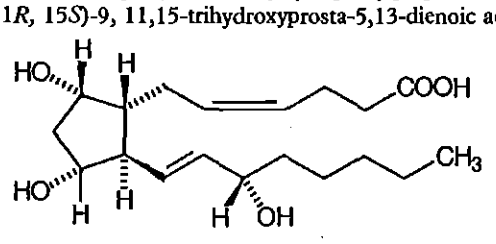
F.4 Where peptide sequences are shown using 3-letter symbols all amino acids except glycine have the 'L-' configuration unless otherwise indicated.

G. Prostaglandins

G.1 Members of the prostaglandin group of substances are conveniently named by reference to prostanoic acid, 12, using the numbering shown. Prostanoic acid may be systematically named as 7-[(1*S*, 2*S*)-2-octylcyclopentyl]heptanoic acid. *Dinoprost*, 13, may therefore be named as (5*Z*,12*E*)-(9*S*, 11*R*, 15*S*)-9, 11,15-trihydroxyprosta-5,13-dienoic acid.

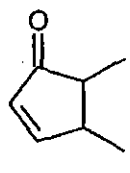


12

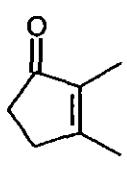


13

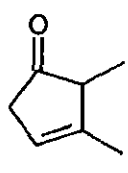
G.2 A convenient trivial nomenclature exists by which prostaglandins (PG) are classified into groups A to F according to the substitution pattern in the cyclopentane ring (shown below). The subscript numerals 1, 2 and 3 refer to the number of double bonds found in the side-chains and subscript a refers to the configuration of the C-9 hydroxy group. Thus, 13 is referred to as PGF_{2a}.



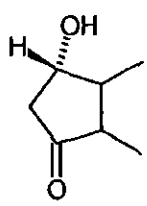
A



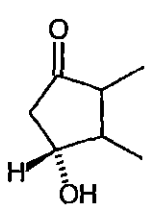
B



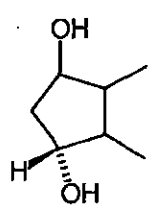
C



D



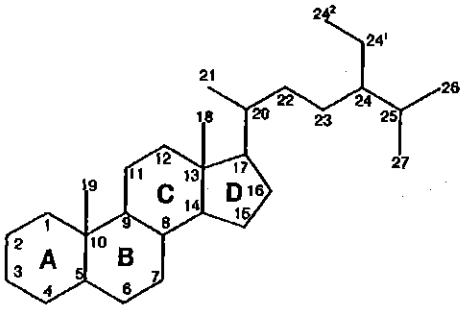
E



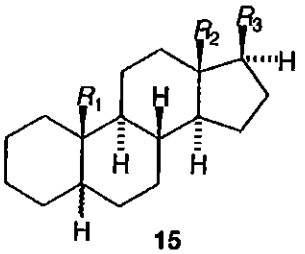
F

H. Steroids

H.1 Steroids are drawn and numbered, and the rings lettered, as shown in 14.



14

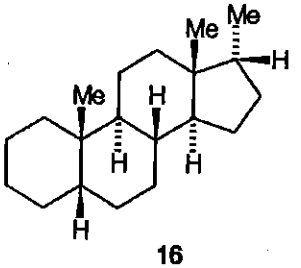


15

H.2 Steroids are named with reference to certain basic carbocycles some of which are defined in Table I. When so drawn, dotted bonds are regarded as lying below the plane of the paper and are designated a, thickened bonds are regarded as lying above the plane of the paper and are designated b and bonds of unknown configuration are shown by a wavy line and are designated x.

Table I

	R_1	R_2	R_3
Gonane	H	H	H
Estrane	H	Me	H
Androstane	Me	Me	H
Pregnane	Me	Me	Et



16

H.3 When the hydrogen atom at C-5 is present, its configuration is always specified, eg 5a-pregnane, 5b-androstane. The configuration at centres, 8,9,10,13,14 and 17 is assumed to be as shown in 15 unless otherwise specified.

H.4 When inversion of the normal configuration occurs, the positions concerned are specified; and thus 16 is named 5b,17a-pregnane.

H.5 When inversion occurs at all of the defined asymmetric centres, the original name is preceded by the italicised prefix *ent-*. Racemates are indicated by use of the italicised prefix *rac-*.

H.6 Further fundamental carbocycles are defined thus:

Table II

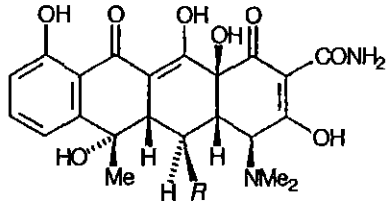
Side-chain	carbon positions present
Cholane	20 - 24
Cholestane	20 - 27
Ergostane	20 - 27, 24^1

In addition to retaining the configuration shown in 15, C-20 has an *R*-configuration in each carbocycle and C-24 in ergostane has an *S*-configuration. However, additional substituents at positions C-17, C-20, C-21 may alter the *R* and *S* propriety descriptions without any change at C-20.

H.7 A large number of therapeutically active steroids bear a carbonyl group at position 3 and unsaturation across positions 4 and 5. Ring A is often aromatic in estrogens.

J. Tetracyclines

J.1 The tetracycline antibiotics are conveniently named by reference to tetracycline itself, 17, (R = H), which may be defined as (4*S*,4a*S*,5a*S*,6*S*,12a*S*)-4-dimethylamino-1,4,4a,5a,6,11,12a-octahydro-3,6,10,12,12a-pentahydroxy-6-methyl-1,11-dioxonaphthacene-2-carboxamide.



17

J.2 When analogues of tetracycline are named the stereodescriptors R and S may be subject to change even though the steric configuration usually remains unchanged. For example, in oxytetracycline, the hydroxyl group at position 5 imposes assignment inversions at positions 4a and 5a from S to R although the steric configuration at these positions remains unchanged.

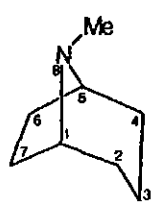
Table III

	Position					
	4	**4a**	**5**	**5a**	**6**	**12a**
Chlortetracycline	*S*	*S*	–	*S*	*S*	*S*
Clomocycline	*S*	*S*	–	*S*	*S*	*S*
Demeclocycline	*S*	*S*	–	*S*	*S*	*S*
Doxycycline	*S*	*R*	*S*	*R*	*R*	*S*
Meclocycline	*S*	*R*	*S*	*R*	–	*S*
Methacycline	*S*	*R*	*S*	*R*	–	*S*
Minocycline	*S*	*S*	–	*R*	–	*S*
Oxytetracycline	*S*	*R*	*S*	*R*	*S*	*S*
Tetracycline	*S*	*S*	–	*S*	*S*	*S*

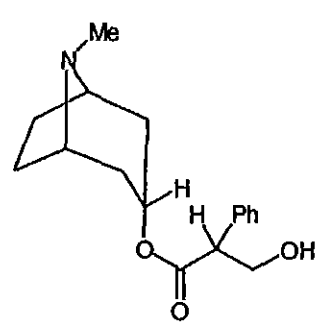
J.3 When fully systematic names based on naphthacene-2-carboxamide are used, the stereodescriptors given in Table III should be used.

K. Tropanes

K.1 Members of the tropane group of substances are conveniently named by references to tropane itself, 18, when the numbering and orientation shown are used. Tropane is defined as (8*r*)-*N*-methyl-8-azabicyclo[3.2.1]octane.



18



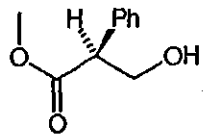
19

K.2 Atropine, **19**, is (1*R*,3*r*,5*S*,8*r*) tropan-3-yl (*RS*)-tropate where the term *tropate* represents 3-hydroxy-2-phenylpropionate.

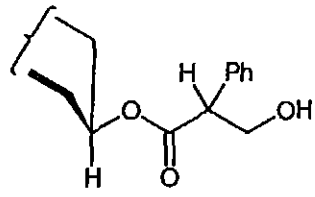
K.3 In the (–)-series the tropoyl side-chain has the (*S*) configuration, **20**.

K.4 In y-tropane compounds, **21**, the configuration at position-3 is designated as '3s'.

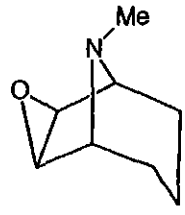
K.5 In hyoscine and other atropine derivatives bearing a 6,7-epoxy bridge, the configuration is as shown in **22**.



20



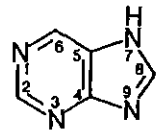
21



22

L. Xanthines

Members of the xanthine group of substances are conveniently named by reference to purine, **23**, when the non-systematic numbering shown is used.



23

Supplementary Chapter III

Pharmacopoeial Organisation

This Supplementary Chapter provides information that may be helpful to those wishing to communicate with the British Pharmacopoeia Commission.

A1. Contact Points

The following table gives an indication of the member of the British Pharmacopoeia Secretariat responsible for particular areas of the Commission's work. The contact number is +44 (0)20 3080 followed by the extension listed in the table below.

B. Monograph Development: Mechanism

The following Supplementary Chapter provides an outline of the mechanism by which monographs are selected and developed for inclusion in the British Pharmacopoeia.

The British Pharmacopoeia Commission will not usually develop monographs for drug substances or excipients. These will usually be elaborated by the European Pharmacopoeia Commission.

The British Pharmacopoeia Commission will consider a monograph for inclusion in the British Pharmacopoeia in the following circumstances:

1. The formulation is widely used (for example: products in the top 500 list of prescribed items; products in the top 100 list of items used in hospitals; Pharmacy (P) and General Sale List (GSL) products that are widely used, taking into account seasonal fluctuations; veterinary products that are widely used or where a need is identified).

2. The innovator product is approaching or past its patent expiry date (monographs will usually only be prepared in the two years preceding patent expiry. However there may be circumstances where it is justified to prepare a monograph at an earlier stage. These will be considered by the British Pharmacopoeia Commission individually).

3. There is a particular need based on the therapeutic category and/or the importance of the material concerned; the latter being particularly relevant to small patient populations.

4. Unlicensed products that are produced to meet particular patient needs (generally "specials" manufacture or extemporaneous preparation) (see also Supplementary Chapter V A).

5. The product/preparation is a widely used traditional herbal medicine.

6. The legal classification of the product has been changed from POM (prescription only medicine) to P or from P to GSL.

7. The product falls within a "family" of product presentations, of which there are already published monographs and/or monographs on the work programme.

8. Drug substances or excipients which are not on the European Pharmacopoeia work programme, but for which there is a specific UK need.

9. A request is received from the Competent Authority [Medicines and Healthcare Products Regulatory Agency (MHRA)].

10. A request is received from a manufacturer for one of their own products.

11. Support for relevant EC directives.

12. A request is received from official bodies [such as the World Health Organization (WHO)].

13. Other circumstances considered on a case-by-case basis.

It should be noted that compliance with any of the above criteria will not necessarily mean that a monograph will be included in the British Pharmacopoeia. The British Pharmacopoeia Commission may decide not to elaborate a monograph for a number of reasons, including a lack of interest from stakeholders, resource limitations or other circumstances, decided on a case-by-case basis.

The diagram provides a simplified, schematic representation of the development of a monograph for a medicinal substance or an associated formulated preparation.

C. Monograph Development: Guidance to Manufacturers

Bulk drug substances

Each monograph, taken as a whole, should provide a reliable basis for making an independent judgement as to the quality of the substance in the interests of the protection of the public. General guidance as to the types of test required and the level of control considered appropriate can be obtained by reference to current BP monographs for similar chemical entities where such are available. In general any monograph for a bulk drug substance should include the features listed below.

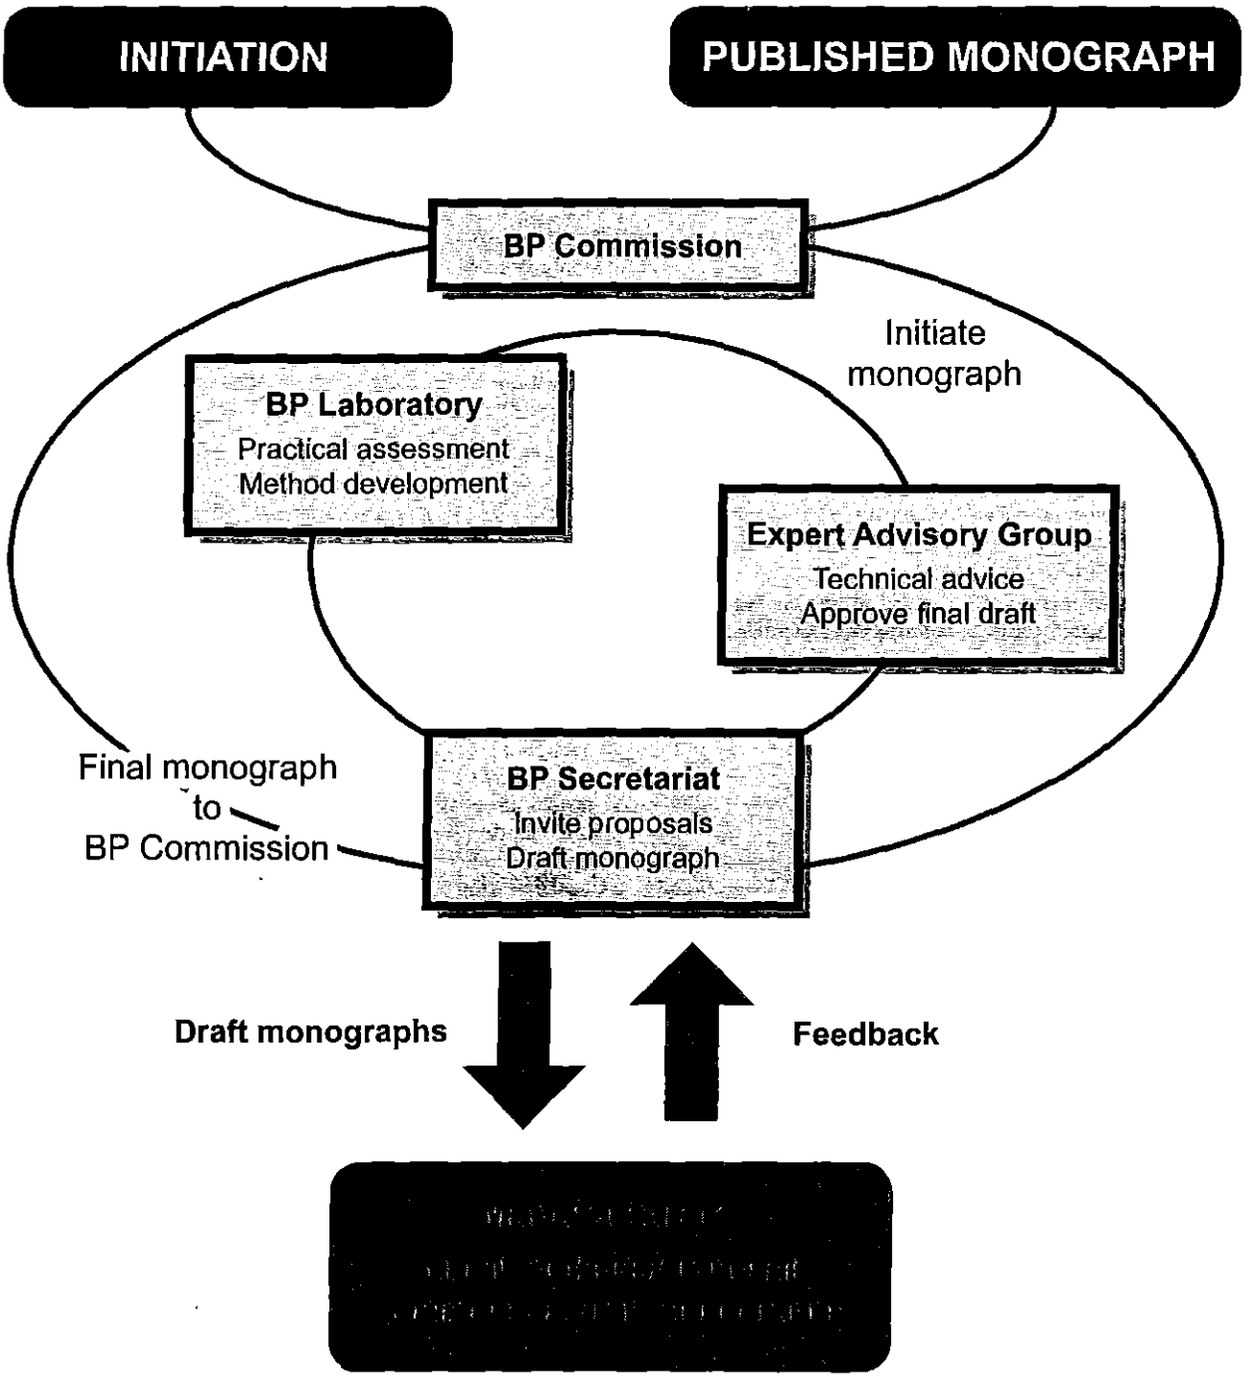
Attention is drawn to the General Notices of the Pharmacopoeia, to the general methods described in the Appendices, to the basis of pharmacopoeial requirements as described in Supplementary Chapter I and to other information provided in the Supplementary Chapters of the Pharmacopoeia.

1. **Definition/Characteristics** Brief description of physical form of material; whether hygroscopic. It would be helpful if information concerning polymorphism could be provided (see Supplementary Chapter I B).

2. **Solubility** Solubility in water, alcohol and at least one common organic solvent, expressed quantitatively or using defined BP terms.

3. **Identification** Qualitative tests capable of unequivocally establishing the identity of the substance. Infrared spectrometry is preferred, or if this is not possible, 2 or 3 identification tests to identify different characteristics of the substance may be used. A test for the counter ion should be included where appropriate.

4. **Impurities** (see also Supplementary Chapter I A) Both related substances and any other impurities that may be present in the substance as a result of the method of manufacture or from degradation on storage. It would be helpful to know the nature of such impurities, the reason for their presence (for example, by-product of synthesis, hydrolysis product, etc.), the amounts that may be encountered in material prepared under conditions of Good Manufacturing Practice and the manner in which the proportions may vary on storage. An indication of the toxicity of any impurities in relation to that of the substance itself and methods for their detection and control would enable the Committee preparing the monograph to decide whether control tests are necessary and, if so, the methods and limits to be applied. In many cases, it is possible to limit impurities



in chromatographic tests using a dilute solution of the substance being examined, and this is the preferred approach, wherever possible. In other cases, for example, where the response factor of an impurity is significantly different from that of the substance (outside the range 0.8 to 1.2), or where a stringent limit is necessary for toxicity reasons, a reference material is required (see paragraph 11 below and Supplementary Chapter III E).

Impurities other than related substances that might require control include inorganic impurities and residues of solvents and reagents used during synthesis and purification. Non-specific purity tests such as light absorption, specific optical rotation and sulfated ash should also be considered.

5. **Transparency** In keeping with BP policy on monograph transparency a suitable statement will be added to appropriate new monographs for medicinal substances giving the identities of impurities known to be limited by the specifications. It is to be emphasised that such statements are not intended to be exclusive and other, unnamed impurities may also be limited. Manufacturers are requested to provide information for such statements (see paragraph 4 above).

6. **Assay** Method and proposed limits calculated with reference to the anhydrous, dried or solvent-free material as appropriate. For bulk drug substances, it has been BP policy *generally* to use a robust and precise method of assay (such as titration) rather than a specific, but sometimes less precise, stability-indicating method (such as liquid chromatography). Wherever possible, control of potential impurities is provided separately by means of specific impurity tests (see paragraph 4 above). It is appreciated, however, that a manufacturer may use, and therefore propose, a chromatographic method for both related substances and assay. In such circumstances,

each case is judged on its merits on the basis of the data provided, which must relate to validated methods. Such methods normally require the establishment of a reference material of the substance with a declared content (see paragraph 11 below and Supplementary Chapter III E). Adequate means of demonstrating system suitability will need to be included in the monograph so that the analyst has an assurance that the results are accurate. As stated above, each monograph, taken as a whole, should provide a reliable basis for making an independent judgement as to the quality of the substance.

7. **Other tests** A test for water or for loss on drying is usually required.

8. **Storage** Any special storage conditions such as protection from light.

9. **Labelling** Any special labelling statements (see Supplementary Chapter I G).

10. **Preparations** Pharmaceutical dosage forms normally available and information on dose.

11. **Samples** A quantity of the material sufficient to carry out in duplicate all the tests and the assay in the proposed specification should be supplied (10 g is usually suitable). This sample should be taken from a typical production batch, that is, it should not be specially purified. In addition appropriate amounts of possible impurities should be supplied (0.1 to 0.5 g is usually suitable).

Many monographs require the use of one or more reference substances (BPCRS); these are established by the Laboratory before publication of the monograph (see Supplementary Chapter III E). If a reference substance for assay purposes is required (see paragraph 6 above) or for impurity control (see paragraph 4 above), please indicate if adequate supplies will be available. About 50 g of material is required to establish a reference material for an assay standard and about 10 g of a named impurity (see also Supplementary Chapter III E). If it is perceived that an ongoing supply of sufficient quantities of material(s) will not be possible, this should be drawn to the attention of the BP Secretariat so that an alternative approach may be considered.

When sending samples, Material Safety Data Sheets that comply with COSHH Regulations should be supplied for all materials including impurities, so that Pharmacopoeia staff are aware of possible hazards when handling these materials.

12. **Supporting data** Appropriate and relevant validation data relating to the proposed analytical procedures and methodology should be provided (see Supplementary Chapter III F). In particular, data to demonstrate the stability indicating nature of methods (i.e. forced degradation studies) and information identifying both synthetic impurities and degradation products should be provided. Additionally, appropriate and relevant batch and stability data to support the proposed specifications should be provided. This information will be kept confidential to the BP Secretariat and Laboratory and to the relevant Expert Advisory Group(s) of the British Pharmacopoeia Commission.

13. **Advice** The BP Secretariat is pleased to provide advice to manufacturers on the nature and extent of data required. It is appreciated that for some older products information on the identity of impurities and/or validation data for methods is not as substantial as that which is required for new chemical entities and advice in these cases is available. A list of contact points in the Secretariat is to be found in Supplementary Chapter III A.

Formulated preparations

Each monograph, taken as a whole, should provide a reliable basis for making an independent judgement as to the quality of the preparation in the interests of the protection of the public. General guidance as to the types of test required and the level of control considered appropriate can be obtained by reference to current BP monographs for the same dosage form of similar chemical entities where such are available. Reference should also be made to any general monograph for the dosage form in question for general requirements and any exceptions to, or modifications of, those requirements noted. In general any monograph for a formulated preparation should include the features listed below.

Attention is drawn to the General Notices of the Pharmacopoeia, to the general methods described in the Appendices, to the basis of pharmacopoeial requirements as described in the Introduction and Supplementary Chapter I and to other information provided in the Supplementary Chapters of the Pharmacopoeia.

1. **Definition/Description** A definition of the preparation in terms of the active ingredient(s) together with information on its presentation.

For sterile preparations (parenteral, ophthalmic and others) this should include information on the nature of the vehicle; the nature of any additives (eg antimicrobial preservatives, buffers) present; the method of sterilisation. In addition, for parenteral preparations information should be provided on whether it is a solution, a suspension, a dry powder or a concentrate for dilution.

For topical semi-solid preparations this should include information on the type of basis (water-in-oil, oil-in-water, etc) and the particle size of the active ingredient, if significant.

For tablets this should include whether or not they are coated. Where tablets are coated, the reason for coating should be provided.

Information concerning polymorphism should be included where relevant (see Supplementary Chapter I B).

2. **Content statement** Proposed limits as a percentage of the stated content of the active ingredient in the terms declared on the label (see Supplementary Chapter I F).

The purpose of the assay in preparation monographs is to determine whether the content of the active ingredient is within acceptable limits of the labelled claim and the limits are therefore of necessity stated in terms of *the moiety declared on the label*. That is, the same method of expression is used in the content statement as under the headings Assay and Labelling. The preferred means of expression is in terms of the therapeutically active part of the molecule. It should be noted that the mode of expressions chosen for the assay limits in the monograph for the bulk drug substance in no way circumscribes that which may be used in the monograph for the formulation.

3. **Identification** Identification tests should be based on those for the parent drug substance where applicable, with details of any necessary preliminary treatment such as extraction. Infrared spectrometry is preferred. A single liquid-chromatographic method for Identification, control of impurities, and Assay should be supplemented by an additional test for identification.

4. **Impurities** [As under Bulk drug substances] Additional information on any impurities arising on manufacture or storage of the dosage form.

The tests applied to the bulk drug substance, including those for impurities arising in manufacture of the bulk drug substance, should be applied, wherever possible - with any necessary modification - in order to demonstrate that material of pharmacopoeial quality has been used in making the formulation.

5. **Transparency** In keeping with BP policy on monograph transparency a suitable statement will be added to appropriate new monographs for formulated preparations giving the identities of impurities known to be limited by the specifications. It is to be emphasised that such statements are not intended to be exclusive and other, unnamed impurities may also be limited. Manufacturers are requested to provide information for such statements (see paragraph 4 above).

6. **Assay** The method of assay will not necessarily be that used for the bulk drug substance. For formulated preparations a specific, stability-indicating method is preferred. Such methods normally require the establishment of a reference material of the substance with a declared content (see paragraph 11 below and Supplementary Chapter III E).

7. **Other tests** Tests such as pH and clarity and colour of solution may be necessary depending on the type of dosage form. In addition, for single-dose preparations a test for uniformity of content and, in the case of solid dosage forms, a dissolution test may be required (see Supplementary Chapter I E).

8. **Storage** Any special storage conditions/containers.

9. **Labelling** Any special labelling statements (see Supplementary Chapter I G).

Please provide sample labels, outer packages, leaflets and a copy of the relevant Summary of Product Characteristics (SmPC) or data sheet.

10. **Strengths available/Dose** While no longer included in the published monograph, this information is of assistance during monograph development.

11. **Samples** A quantity of the formulation sufficient to carry out in duplicate all the tests (including those under paragraph 7) and the assay in the proposed specification should be supplied. Samples should be taken from a typical production batch.

The following suggested quantities are provided as a rough guide of the order of sample size for each strength of different dosage forms:

Solid single dose formulations (Tablets, Capsules, etc)	100 units

Liquid formulations

i)	Topical and Oral formulations	100 mL
ii)	Parenteral formulations	50 mL
	Semi-solid topical formulations	50 to 100 g

In addition appropriate amounts of possible impurities (arising from synthesis or degradation) should be supplied (approximately 200 to 500 mg, unless the impurity is required for use as a reference standard, see below)

Many monographs require the use of one or more reference substances (BPCRS); these are established by the Laboratory before publication of the monograph (see Supplementary Chapter III E). If a reference substance is required for assay purposes (see paragraph 6 above), or for impurity control (see paragraph 4 under bulk drug substances), please indicate if adequate supplies will be available. About 50 g of material is required to establish a reference material for an assay standard and about 10 g of a named impurity (see also Supplementary Chapter III E).

When sending samples, Material Safety Data Sheets that comply with COSHH Regulations should be supplied for all materials including impurities, so that Pharmacopoeia staff are aware of possible hazards when handling these materials.

12. **Supporting data** Appropriate and relevant validation data relating to the proposed analytical procedures and methodology should be provided (see Supplementary Chapter III F). In particular, data to demonstrate the stability indicating nature of methods (i.e. forced degradation studies) and information identifying both synthetic impurities and degradation products should be provided. Additionally, appropriate and relevant batch and stability data to support the proposed specifications should be provided. This information will be kept confidential to the BP Secretariat and Laboratory and to the relevant Expert Advisory Group(s) of the British Pharmacopoeia Commission.

13. **Advice** The BP Secretariat is pleased to provide advice to manufacturers on the nature and extent of data required. It is appreciated that for some older products information on the identity of impurities and/or validation data for methods is not as substantial as that which is required for new chemical entities and advice in these cases is available. A list of contact points in the Secretariat is to be found in Supplementary Chapter III A.

D. Monograph Development: Methods of Analysis

1. This Supplementary Chapter concerns the methods described in the Pharmacopoeia for the analysis of medicinal and pharmaceutical substances, pharmaceutical dosage forms and other articles. It provides information on the development, validation and use of pharmacopoeial methods so that users of the Pharmacopoeia may understand the purpose and limitations of a monograph and to guide manufacturers and other users when participating in the development of new monographs and the revision of existing monographs.

2. For further information regarding the elaboration of European Pharmacopoeia monographs, users may also consult the "Technical guide for the elaboration of monographs", which is published by the European Pharmacopoeia.

3. The Chapter does not set out the nature and extent of validation required in particular instances. Guidelines on such matters with respect to product registration are available from other sources such as the International Conference on Harmonisation (ICH) and are published as guideline Q2 (R1), "Validation of Analytical Procedures: Text and Methodology". The terms used, and illustrations of the data requirements to demonstrate that a method satisfies the definitions, are provided in Supplementary Chapter III F.

Method origin

3. Proposals for new or revised methods for inclusion are often provided by manufacturers and other users of the Pharmacopoeia either in response to a request from the Secretariat or Laboratory or, for revised methods, when a published method has been found to be unsuitable for any reason. A method may become unsuitable when, for example, a reagent or piece of apparatus is no longer readily available, knowledge of the material has increased, regulatory

requirements have altered or a more specific or sensitive test has been developed.

4. Any method that is to be considered for inclusion in a monograph has to be suitable for pharmacopoeial purposes and, wherever possible, be accompanied by appropriate supporting data.

4.1 Guidance on the suitability of any method for inclusion in the Pharmacopoeia may be obtained by reference to the General Notices (in particular, those dealing with official standards, excipients, identification and assays and tests) and Supplementary Chapter I concerning the basis of pharmacopoeial requirements. Each monograph, taken as a whole, should provide a reliable basis for making an independent judgement as to the quality of an article in the interests of the protection of the public.

4.2 A pharmacopoeial monograph applies throughout the shelf-life of a formulated preparation or throughout the period of use of a medicinal or pharmaceutical substance and the monograph when taken as a whole must be stability indicating and must be able to assure the quality of the substance throughout its claimed shelf life. Methods for inclusion in the Pharmacopoeia should therefore have been shown to be stability indicating where appropriate by means of forced degradation studies.

4.3 Other than in exceptional circumstances, methods should not specify the use of apparatus that is not widely available in reasonably equipped laboratories nor should they require extensive additional training of laboratory staff. Reagents and reference materials required for a proposed pharmacopoeial method should be generally available from the common sources of supply in the United Kingdom or a manufacturer should be able to supply sufficient quantity for use as a British Pharmacopoeia Chemical Reference Substance (BPCRS). The method should be described in sufficient detail that a competent analyst is able to repeat it.

4.4 Methods proposed by manufacturers should have been adequately validated in accordance with appropriate guidelines (paragraph 2 refers). Exceptionally, full validation data may not be available in some circumstances. For example, not all contributors to the Pharmacopoeia are able to demonstrate the *specificity* of a test method for application to a monograph for a formulated preparation since the nature of the excipients may be unknown; in this case a note of the extent of any validation carried out, with its limitations, is helpful.

4.5 It is of particular importance that method proposals include a robust and reliable identity test(s) for the active component in a substance or formulated preparation. Infrared spectrophotometry is preferred.

4.6 It is also of particular importance that any pharmacopoeial method is *robust* and *reproducible*. Data that demonstrate the transferability of a method are, therefore, especially helpful.

Method elaboration

5. All proposals for new and revised methods for publication are carefully examined. The nature and extent of the evaluation is determined by a number of factors including the following:

— whether the proposal is for a new monograph or for revision of an existing monograph,
— extent of validation and batch data available,
— how many specifications and/or samples are available for examination,
— complexity of the proposed method.

6. The evaluation of methods is carried out by the Commission's Expert Advisory Groups and Panels of Experts, the Secretariat and the Laboratory; practical evaluation is included in many cases. If necessary, more extensive practical work is carried out in consultation with the proposer of the method. Such practical work may be necessary, for example, where a proposed method is not directly applicable to other sources of the material or preparation or is shown to be insufficiently *robust* for pharmacopoeial use.

7. After initial evaluation, the method is drafted in the style of the Pharmacopoeia and those known to have an interest in the material or preparation are invited to comment. If necessary, further modifications may be made to the method and the consultation process repeated before the method is published. A diagrammatic representation of the process of monograph elaboration is provided as Supplementary Chapter III B.

Published methods

8. The user can expect that published methods:

are suitable for the purpose for which they are described in the Pharmacopoeia, have been evaluated and, where necessary, modified as described in the preceding section,

have been shown to be adequately validated, as appropriate to the type of test, and include tests to demonstrate the continuing suitability of the method, where necessary,

are described in sufficient detail that a competent analyst can perform the test using readily available apparatus and reagents and that any necessary reference materials are available, will be reviewed and revised when experience shows this to be necessary.

9. The user cannot, however, assume that a method forming part of a pharmacopoeial monograph will have been applied to all sources of a raw material or to all formulations of a dosage form currently available. The user is responsible for confirming that the method is applicable to the particular material being examined. It is essential that a manufacturer carries out sufficient checks to demonstrate that, for example, impurities arising from a new route of synthesis are controlled by the methods described in the monograph or that the excipients in a formulated preparation do not interfere with any of the tests in a monograph. It should be noted that an article cannot claim to be of pharmacopoeial quality unless it can be shown to comply with all of the tests specified in a monograph (see General Notice on Official Standards).

Feedback

The British Pharmacopoeia Commission welcomes constructive comments from users on the tests of the Pharmacopoeia and it is through such feedback that revision of the tests is initiated. A list of contact points in the Secretariat is to be found in Supplementary Chapter III A.

E. British Pharmacopoeia Chemical Reference Substances (BPCRS)

1. The current list of BPCRS may be found on the BP's website at *www.pharmacopoeia.com*. The quantity of material supplied is sufficient to carry out in duplicate each of the tests in which it is used in any one monograph.

Requirement

2. The establishment of a new BPCRS is based on scientific necessity following advice from the British Pharmacopoeia Commission's Expert Advisory Groups. A reference substance for the medicinal substance is usually required for specific, stability-indicating assays and may also be required for identification purposes. A reference substance for an impurity is required when control using a dilute solution of the substance being examined is not possible or is undesirable. Such cases include those where the response factor of the impurity is significantly different from that of the substance, or where it is necessary to limit a named impurity (see Supplementary Chapter I A).

The following criteria are taken into account when determining whether a new BPCRS is required.

Availability of the material A commercially available reagent is specified wherever it is found to be suitable and justified.

Analytical convenience Wherever possible, either the same EPCRS or the same BPCRS is specified throughout any one monograph.

Establishment

3. Manufacturers who have contributed to the development of the monograph(s) are asked to supply material for use as reference substances. Normally, about 50 g is required for an Assay standard and about 10 g for an impurity. In some cases it is possible to use a quantity of the medicinal substance admixed with smaller quantities of the impurities as an impurity reference standard. It would be helpful if manufacturers could indicate the likely availability of reference materials at an early stage during monograph development.

4. The materials are tested by the Laboratory to confirm their suitability for the intended purpose and are made available not later than the effective date of the monograph in which they are used.

Monitoring and replacement

5. All substances used for quantitative analyses are re-tested every three years and materials used for qualitative analysis every five years unless experience has shown that more frequent testing is necessary.

6. When a BPCRS is due for replacement (because of a fall in quality or exhaustion), a review of the use of the material and the number of units supplied is carried out.

Continued availability

7. When a monograph is omitted from the Pharmacopoeia the last published monograph remains the legal standard. As the usual reason for omission is low and declining use or withdrawal of the material from the market, demand for any associated reference substances from within the United Kingdom is normally low.

8. It is not possible to maintain reference substances for omitted materials indefinitely and, for materials no longer marketed in the United Kingdom, it is difficult to obtain replacement stocks. As a service to analysts, reference substances for monographs omitted from the current edition of the Pharmacopoeia are normally retained for about five years from the date of publication of the current edition unless the material becomes unsatisfactory or the supply is exhausted before that date.

9. Demand is monitored and any significant increase in demand for a reference substance for an omitted monograph is noted. If such increased demand appears to stem from a renewed interest in the medicinal or pharmaceutical product, consideration may be given to reinstating the monograph in the Pharmacopoeia.

F. Validation of Analytical Procedures

Introduction

Validation of an analytical procedure is performed in order to demonstrate that the procedure is suitable for its intended use. Validation is performed in order to show that the result(s) generated by a particular analytical procedure are reliable and accurate.

The principles and practices of validation of analytical procedures are covered by the International Conference on Harmonisation (ICH), are published as guideline Q2(R1), "Validation of Analytical Procedures: Text and Methodology" and are available from www.ich.org. A full discussion of the terms and methodology applicable to validation of analytical procedures is provided in the ICH documents.

Types of procedures to be validated

The objective of validation of an analytical procedure is to demonstrate that it is suitable for its intended purpose. A tabular summation of the characteristics applicable to identification, control of impurities and assay procedures is included.

Specificity

Specificity is the ability to assess unequivocally the analyte in the presence of components that may be expected to be present. Typically these might include impurities, degradants, matrix, etc.

Specificity may often be expressed as the degree of bias of test results obtained by analysis of samples containing added impurities, degradation products, related chemical compounds, or placebo ingredients when compared to test results without added substances.

Specificity is usually demonstrated by measuring the response of the sample matrix and any expected or known species (for example excipients, impurities or degradation products). It would normally be expected that no significant response would be obtained that interferes with the measurement of the analyte(s). However it is not always possible that an analytical procedure is specific for a particular analyte. In this instance a combination of two or more analytical procedures may be necessary to achieve the required discrimination.

Linearity

The linearity of an analytical procedure is its ability (within a given range) to obtain test results that are directly proportional to the concentration (amount) of analyte in the sample.

Linearity is usually demonstrated by visual inspection of a plot of signals as a function of analyte concentration or content. If there is a linear relationship, test results should be evaluated by appropriate statistical methods, for example, by calculation of a regression line by the method of least squares. In some cases, to obtain linearity between assays and sample concentrations, the test data may need to be

Type of analytical procedure characteristics	IDENTIFICATION	TESTING FOR IMPURITIES quantitat.	 limit	ASSAY - dissolution (measurement only) - content/potency
Accuracy	-	+	-	+
Precision				
Repeatability	-	+	-	+
Interm. Precision	-	+ (1)	-	+ (1)
Specificity (2)	+	+	+	+
Detection Limit	-	- (3)	+	-
Quantitation Limit	-	+	-	-
Linearity	-	+	-	+
Range	-	+	-	+

- signifies that this characteristic is not normally evaluated
+ signifies that this characteristic is normally evaluated
(1) in cases where reproducibility has been performed, intermediate precision is not needed
(2) lack of specificity of one analytical procedure could be compensated by other supporting analytical procedure(s)
(3) may be needed in some cases

subjected to a mathematical transformation prior to the regression analysis. Data from the regression line itself may be helpful to provide mathematical estimates of the degree of linearity.

The correlation coefficient, y-intercept, slope of the regression line and residual sum of squares should be calculated. A plot of the data should be included.
In addition, an analysis of the deviation of the actual data points from the regression line may also be helpful for evaluating linearity.

A minimum of five concentrations is recommended. Other approaches should be justified.

Accuracy
The accuracy of an analytical procedure expresses the closeness of agreement between the value which is accepted either as a conventional true value or an accepted reference value and the value found. This is sometimes termed trueness.

Accuracy should be established across the specified range of the analytical procedure.

Accuracy is usually demonstrated by adding known amounts of analyte(s) to the sample matrix and determining the measured result using the analytical procedure. The recovery of measured against actual amounts is then calculated.
Usually a minimum of three determinations at each of three concentrations across the intended range is recommended.

Accuracy may also be demonstrated by the method of standard additions, or by cross-correlation of results with a second, independent, procedure. Accuracy may be inferred once precision, linearity and specificity have been established.

Precision
The precision of an analytical procedure expresses the closeness of agreement (degree of scatter) between a series of measurements obtained from multiple sampling of the same homogeneous sample under the prescribed conditions. Precision may be considered at three levels: repeatability, intermediate precision and reproducibility.

Precision should be investigated using homogeneous, authentic samples. However, if it is not possible to obtain a homogeneous sample it may be investigated using artificially prepared samples or a sample solution.

The precision of an analytical procedure is usually expressed as the variance, standard deviation or coefficient of variation of a series of measurements.

Repeatability (intra-assay precision)
Repeatability expresses the precision under the same operating conditions over a short interval of time. Repeatability is also termed intra-assay precision.

Repeatability is usually demonstrated by repeated measurements of a single sample (e.g. use of the analytical procedure within a laboratory over a short period of time using the same analyst with the same equipment).
A minimum of three determinations at each of three concentrations across the intended range, or a minimum of six determinations at the test concentration is recommended.

Intermediate Precision
Intermediate precision expresses within-laboratory variations: different days, different analysts or equipment, etc.

Intermediate precision is usually demonstrated by repeated measurements of the sample used in the repeatability

experiment within the same laboratory. Usually the repeatability experiment is repeated on the same sample by a different analyst, on a different day, using different equipment if possible.

Reproducibility

Reproducibility expresses the precision between laboratories (collaborative studies, usually applied to standardisation of methodology).

Reproducibility is usually demonstrated by means of an inter-laboratory trial.

Detection Limit

The detection limit of an analytical procedure is the lowest concentration of analyte in a sample that can be detected but not necessarily quantitated as an exact value.

The detection limit is usually expressed as the concentration of analyte (e.g., percentage, parts per billion) in the sample.

The detection limit is usually demonstrated by measuring low concentrations of the analyte and showing that a response is obtained.

Quantitation Limit

The quantitation limit of an individual analytical procedure is the lowest amount of analyte in a sample which can be quantitatively determined with suitable precision and accuracy. The quantitation limit is a parameter of quantitative assays for low levels of compounds in sample matrices, and is used particularly for the determination of impurities and/or degradation products.

It is usually expressed as the concentration of analyte (e.g. percentage, parts per billion) in the sample.

The quantitation limit is usually demonstrated by measuring low concentrations of the analyte and showing that a repeatable response is obtained.

Robustness

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage.

Robustness is usually demonstrated by making small deliberate changes to one of the operating parameters of the method, analysing samples and comparing the results to those obtained using the prescribed method.

Range

The range of an analytical method is the interval between the upper and lower concentration (amounts) of analyte (including these concentrations) for which it has been demonstrated that the analytical procedure has a suitable level of precision, accuracy and linearity.

The specified range is normally derived from linearity studies and depends on the intended application of the procedure. It is established by confirming that the analytical procedure provides an acceptable degree of linearity, accuracy and precision when applied to samples containing amounts of analyte within or at the extremes of the specified range of the analytical procedure.

For assays the range is usually not less than 80 to 120% of the test concentration.

For determination of content uniformity the range is usually not less than 70 to 130% of the test concentration.

For determination of impurities the range is usually not less than the reporting limit of the impurity to 120% of the specification.

For dissolution testing the range is usually +/- 20% over the expected concentrations.

Range is usually demonstrated by confirming that the analytical procedure provides an acceptable degree of linearity, accuracy and precision when applied to samples containing amounts of analyte within or at the extremes of the specified range.

System Suitability Testing

System suitability testing is an integral part of many analytical procedures. The tests are based on the concept that the equipment, electronics, analytical operations and samples to be analyzed constitute an integral system that can be evaluated as such. System suitability test parameters to be established for a particular procedure depend on the type of procedure being validated.

Criteria for assessing the suitability of chromatographic systems are described in the chapter on Chromatographic separation techniques (Appendix III (*Ph. Eur. method 2.2.46*)). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

Supplementary Chapter IV

European Pharmacopoeia

This Supplementary Chapter provides information concerning the European Pharmacopoeia.

A. Membership of the European Pharmacopoeia Commission

In addition to the United Kingdom, the Member States party to the Convention on the Elaboration of a European Pharmacopoeia are as follows: Albania, Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, The Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Montenegro, The Netherlands, Norway, Poland, Portugal, Republic of Moldova, Romania, Serbia, Slovak Republic, Slovenia, Spain, Sweden, Switzerland, The Former Yugoslav Republic of Macedonia, Turkey and Ukraine. The European Union is also party to the Convention.

Observers to the European Pharmacopoeia Commission at the time of publication are: Algeria, Argentina, Armenia, Australia, Azerbaijan, Belarus, Brazil, Canada, China, Georgia, Guinea, India, Israel, Japan, Kazakhstan, Republic of Korea, Madagascar, Malaysia, Mexico, Morocco, The Russian Federation, Senegal, Singapore, South Africa, Syria, Tunisia, the United States of America, Uzbekistan, the Taiwan Food and Drug Administration (TFDA) and the World Health Organization (WHO).

The United Kingdom delegation to the European Pharmacopoeia Commission up to 31 December 2021 was as follows:

Professor A Davidson

Mr J Pound

Professor K Taylor

Alternate members of the United Kingdom delegation up to 31 December 2021 were as follows:

Mr A Gibb

Dr R Horder

Mr S Young

UK Membership of Groups of Experts of the European Pharmacopoeia Commission

The United Kingdom is represented in all of the major Groups of Experts of the European Pharmacopoeia Commission. The UK membership of the Groups on 1 January 2021 is as listed in the table below.

1	Microbiology	Mr M Whaley
6	Biological Substances	Dr B Cowper
6B	Human Blood and Blood Products	Dr C Thelwell
7	Antibiotics	Mr J Sumal
9G	Medicinal Gases	Mr P Henrys *(Chairman)*
10A	Organic Chemistry (Synthetic Products)	Mr D Malpas *(Specialist)*
10B	Organic Chemistry (Synthetic Products)	Dr E Bush
10C	Organic Chemistry (Synthetic Products)	Dr J Mckendrick
10D	Organic Chemistry (Synthetic Products)	Mr C T Goddard
11	Organic Chemistry (Natural Products)	Ms H Corns
12	Dosage Forms and Methods	Dr R Horder *(Chairman)* Dr E Gray
13B	Phytochemistry B	Mr P Anderson
14	Radioactive Compounds	Dr R D Pickett
15	Sera and Vaccines	Dr P Stickings Dr S Schepelmann *(Specialist)*
15V	Veterinary Sera and Vaccines	Dr A-M Brady *(Specialist)* Dr R Cooney
17	Medicinal Products containing Chemically Defined Active Substances	Mr S Young
P4	Procedure 4	Mr A Evans

UK Membership of Working Parties of the European Pharmacopoeia Commission

The UK membership of the Working Parties on 1 January 2021 is as follows.

Alkyl Mesilates	*Vacant*
Bacterial Endotoxins Test	Dr Karin Nordgren
Cell Therapy Products	Ms K Cornish
Chromatographic Separation Techniques	Mr S Young
Excipient Performance	*Vacant*
Extracts	Dr M Pires
General Methods	Dr E Gray
Gene Therapy	Dr Y Zhao
Host-cell Proteins	Dr A Kippen
Inhalanda	Professor K Taylor
Monoclonal Antibodies	Dr S Prior
	Dr P Varley
	Dr M Wadhwa
Mycoplasma	Mr R Hawkins
Paediatric Formulary	Dr K Boon
Pyrrolizidine Alkaloids	Ms S Macdonald
P4 Procedure 4 for Biologicals	Dr L Both
	Dr M Wadhwa
Raw Materials for the Production of Cellular and Gene Therapy Products	Dr L Bisset
Rules of Procedure	Mr A Gibb
Special Revision Programme	Mr A Evans
Standard Terms	Dr M Ahmed
Statistics	Dr R Gaines Das

B. Dates of Implementation

Under the 1964 Convention[1] on the Elaboration of a European Pharmacopoeia the standards of the European Pharmacopoeia are required to take precedence over the standards of the national pharmacopoeias of the contracting parties, thus ensuring a common standard.

In addition to the United Kingdom the countries party to the Convention are: Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, The Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Montenegro, The Netherlands, Norway, Poland, Portugal, Romania, Serbia, Slovakia, Slovenia, Spain, Sweden, Switzerland, The Former Yugoslav Republic of Macedonia, Turkey and Ukraine. The European Union is also party to the Convention.

The 10th Edition, published in July 2019, came into force on 1 January 2020 and will be amended by Supplements 10.1 to 10.8. The publication remains in force until 31 December 2022 and the supplements are non-cumulative.

The date of entry into force of each publication is agreed by the members of the Convention. For new texts and monographs the agreed date is the latest date by which all member states must have implemented the standard but for replacement texts and monographs the standard enters into force on the same day in all states party to the Convention.

The dates of entry into force of the monographs in the 10th Edition and Supplements are given in the Table below.

Publication	Implementation Date
10th Edition	1 January 2020
Supplement 10.1	1 April 2020
Supplement 10.2	1 July 2020
Supplement 10.3	1 January 2021
Supplement 10.4	1 April 2021
Supplement 10.5	1 July 2021
Supplement 10.6	1 January 2022
Supplement 10.7	1 April 2022
Supplement 10.8	1 July 2022

To provide the user of the British Pharmacopoeia with a comprehensive reference to pharmacopoeial standards applicable in the United Kingdom, monographs of the European Pharmacopoeia, as amended by the Supplements, are included in the British Pharmacopoeia or the British Pharmacopoeia (Veterinary), as appropriate (see the General Notice on the European Pharmacopoeia).

Where the title of the monograph entry included in the British Pharmacopoeia is different from the English title of the European Pharmacopoeia monograph, an approved synonym has been created by the British Pharmacopoeia Commission (see Appendix XXI B).

[1] *The Convention on the Elaboration of a European Pharmacopoeia (European Treaty Series No. 50; UK Treaty Series No.32 (1974) CMND 5763) as amended by the Protocol (European Treaty Series No. 134; UK Treaty Series No. MISC16 (1990) CMND 1133).*

C. Certification Scheme

1. The scheme is operated in accordance with the procedures described in Council of Europe Resolution AP-CSP(07) 1. Additional information, including a list of certificates granted, is published regularly in Pharmeuropa.

2. The scheme has been extended by means of Resolution AP-CSP(07)1 and the Human Medicines Regulations 2012, as amended, to cover active substances or excipients (organic or inorganic, obtained by synthesis, extraction or fermentation), any product with transmissible spongiform encephalopathy (TSE) risk, or herbal products used in the production or preparation of pharmaceutical products.

3. For the established process, the certificate is a '*Certificate of Suitability of a Monograph of the European Pharmacopoeia*'. It certifies that the relevant Ph. Eur. monograph adequately controls the substance as manufactured by the company concerned at the time that the certificate is granted (mainly that the impurity tests are adequate to control the impurity profile associated with the particular source/route of synthesis). It is *not* a *certificate of compliance*. It does not certify that the substance, as manufactured by the company concerned at the time that the certificate is granted, complies with the requirements of the relevant Ph. Eur. monograph.

4. The Certification Scheme is recognised by all signatory states of the European Pharmacopoeia Convention. Canada, Australia, New Zealand, Tunisia and Morocco also recognise the scheme.

5. The certificate is intended to facilitate the licensing process. It can be used to simplify the data required within the Control of starting materials section of an application as stated in the Human Medicines Regulations 2012, as amended. The Certification Scheme is intended to operate in an analogous fashion to that for European Drug Master Files (EDMFs) for which it is the preferred alternative. Its general purpose is to avoid duplication of work by marketing authorisation applicants in preparing dossiers and by the authorities in the assessment process. The scheme also assists in eliminating differences in the interpretation of Ph. Eur. monographs by various competent authorities. The operation of the scheme provides the European Pharmacopoeia Commission with a mechanism for updating monographs, for example, to cover substances made by different manufacturing methods.

6. The scope of the procedure was extended by means of Resolution AP-CSP(07)1. It now covers substances produced by fermentation as indirect gene products, which are metabolites of microorganisms, irrespective of whether or not the microorganisms have been modified by traditional procedures or r-DNA technology and products with risk of transmitting agents of animal spongiform encephalopathies (TSE).

Substances which are direct gene products, such as proteins, and substances obtained from human tissues, vaccines and blood products and preparations remain excluded from the Certification procedure.

The final decision on eligibility of an application for a certificate of suitability for a material of animal origin is taken by the relevant board of the procedure if necessary.

D. Residual Solvents

(Ph. Eur. general texts 5.4)

LIMITING RESIDUAL SOLVENT LEVELS IN ACTIVE SUBSTANCES, EXCIPIENTS AND MEDICINAL PRODUCTS

The International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) has adopted Impurities Guidelines for Residual Solvents which prescribes limits for the content of solvents which may remain in active substances, excipients and medicinal products after processing. This guideline, the text of which is reproduced below, excludes existing marketed products. The European Pharmacopoeia is, however, applying the same principles enshrined in the guideline to existing active substances, excipients and medicinal products whether or not they are the subject of a monograph of the Pharmacopoeia. All substances and products are to be tested for the content of solvents likely to be present in a substance or product.

Where the limits to be applied comply with those given below, tests for residual solvents are not generally mentioned in specific monographs since the solvents employed may vary from one manufacturer to another and the requirements of this general chapter are applied via the general monograph on *Substances for Pharmaceutical Use (2034)*. The competent authority is to be informed of the solvents employed during the production process. This information is also given in the dossier submitted for a certificate of suitability of the monographs of the European Pharmacopoeia and is mentioned on the certificate.

Where only Class 3 solvents are used, a test for loss on drying may be applied or a specific determination of the solvent may be made. If for a Class 3 solvent a justified and authorised limit higher than 0.5 per cent is applied, a specific determination of the solvent is required.

When Class 1 residual solvents or Class 2 residual solvents (or Class 3 residual solvents which exceed the 0.5 per cent) are used, the methodology described in the general method *(2.4.24)* is to be applied wherever possible. Otherwise an appropriate validated method is to be employed.

When a quantitative determination of a residual solvent is carried out, the result is taken into account for the calculation of the content of the substance except where a test for drying is carried out.

IMPURITIES: GUIDELINES FOR RESIDUAL SOLVENTS (CHMP/ICH/82260/2006)

APPENDIX 2. ADDITIONAL BACKGROUND
A2.1 ENVIRONMENTAL REGULATION OF ORGANIC VOLATILE SOLVENTS
A2.2 RESIDUAL SOLVENTS IN PHARMACEUTICALS
APPENDIX 3. METHODS FOR ESTABLISHING EXPOSURE LIMITS

1 INTRODUCTION

The objective of this guideline is to recommend acceptable amounts of residual solvents in pharmaceuticals for the safety of the patient. The guideline recommends the use of less toxic solvents and describes levels considered to be toxicologically acceptable for some residual solvents.

Residual solvents in pharmaceuticals are defined here as organic volatile chemicals that are used or produced in the manufacture of active substances or excipients, or in the preparation of medicinal products. The solvents are not completely removed by practical manufacturing techniques. Appropriate selection of the solvent for the synthesis of active substance may enhance the yield, or determine characteristics such as crystal form, purity, and solubility. Therefore, the solvent may sometimes be a critical parameter in the synthetic process. This guideline does not address solvents deliberately used as excipients nor does it address solvates. However, the content of solvents in such products should be evaluated and justified.

Since there is no therapeutic benefit from residual solvents, all residual solvents should be removed to the extent possible to meet product specifications, good manufacturing practices, or other quality-based requirements. Medicinal products should contain no higher levels of residual solvents than can be supported by safety data. Some solvents that are known to cause unacceptable toxicities (Class 1, Table 1) should be avoided in the production of active substances, excipients, or medicinal products unless their use can be strongly justified in a risk-benefit assessment. Some solvents associated with less severe toxicity (Class 2, Table 2) should be limited in order to protect patients from potential adverse effects. Ideally, less toxic solvents (Class 3, Table 3) should be used where practical. The complete list of solvents included in this guideline is given in Appendix 1.

The lists are not exhaustive and other solvents can be used and later added to the lists. Recommended limits of Class 1 and 2 solvents or classification of solvents may change as new safety data becomes available. Supporting safety data in a marketing application for a new medicinal product containing a new solvent may be based on concepts in this guideline or the concept of qualification of impurities as expressed in the guideline for active substances (*Q3A*, Impurities in New Active Substances) or medicinal products (*Q3B*, Impurities in New Medicinal Products), or all three guidelines.

2 SCOPE OF THE GUIDELINE

Residual solvents in active substances, excipients, and in medicinal products are within the scope of this guideline. Therefore, testing should be performed for residual solvents when production or purification processes are known to result in the presence of such solvents. It is only necessary to test for solvents that are used or produced in the manufacture or purification of active substances, excipients, or medicinal product. Although manufacturers may choose to test the medicinal product, a cumulative method may be used to calculate the residual solvent levels in the medicinal product from the levels in the ingredients used to produce the medicinal product. If the calculation results in a level equal to or below that recommended in this guideline, no testing of the medicinal product for residual solvents need be considered. If however, the calculated level is above the recommended level, the medicinal product should be tested to ascertain whether the formulation process has reduced the relevant solvent level to within the acceptable amount. Medicinal product should also be tested if a solvent is used during its manufacture.

This guideline does not apply to potential new active substances, excipients, or medicinal products used during the clinical research stages of development, nor does it apply to existing marketed medicinal products.

The guideline applies to all dosage forms and routes of administration. Higher levels of residual solvents may be acceptable in certain cases such as short term (30 days or less) or topical application. Justification for these levels should be made on a case by case basis.

See Appendix 2 for additional background information related to residual solvents.

3 GENERAL PRINCIPLES

3.1 CLASSIFICATION OF RESIDUAL SOLVENTS BY RISK ASSESSMENT

The term "tolerable daily intake" (TDI) is used by the International Program on Chemical Safety (IPCS) to describe exposure limits of toxic chemicals and "acceptable daily intake" (ADI) is used by the World Health Organization (WHO) and other national and international health authorities and institutes. The new term "permitted daily exposure" (PDE) is defined in the present guideline as a pharmaceutically acceptable intake of residual solvents to avoid confusion of differing values for ADI's of the same substance.

Residual solvents assessed in this guideline are listed in Appendix 1 by common names and structures. They were evaluated for their possible risk to human health and placed into one of three classes as follows:

Class 1 solvents: solvents to be avoided
Known human carcinogens, strongly suspected human carcinogens, and environmental hazards.

Class 2 solvents: solvents to be limited
Non-genotoxic animal carcinogens or possible causative agents of other irreversible toxicity such as neurotoxicity or teratogenicity.

Solvents suspected of other significant but reversible toxicities.

Class 3 solvents: solvents with low toxic potential
Solvents with low toxic potential to man; no health-based exposure limit is needed. Class 3 solvents have PDEs of 50 mg or more per day.

3.2 METHODS FOR ESTABLISHING EXPOSURE LIMITS

The method used to establish permitted daily exposures for residual solvents is presented in Appendix 3. Summaries of the toxicity data that were used to establish limits are published in *Pharmeuropa*, Vol. 9, No. 1, Supplement April 1997.

3.3 OPTIONS FOR DESCRIBING LIMITS OF CLASS 2 SOLVENTS

Two options are available when setting limits for Class 2 solvents.

Option 1

The concentration limits in parts per million stated in Table 2 can be used. They were calculated using equation (1) below by assuming a product mass of 10 g administered daily.

$$\text{Concentration (ppm)} = \frac{1000 \times \text{PDE}}{\text{dose}} \quad (1)$$

Here, PDE is given in terms of mg/day and dose is given in g/day.

These limits are considered acceptable for all substances, excipients, or products. Therefore this option may be applied if the daily dose is not known or fixed. If all excipients and active substances in a formulation meet the limits given in Option 1, then these components may be used in any proportion. No further calculation is necessary provided the daily dose does not exceed 10 g. Products that are administered in doses greater than 10 g per day should be considered under Option 2.

Option 2

It is not considered necessary for each component of the medicinal product to comply with the limits given in Option 1. The PDE in terms of mg/day as stated in Table 2 can be used with the known maximum daily dose and equation (1) above to determine the concentration of residual solvent allowed in a medicinal product. Such limits are considered acceptable provided that is has been demonstrated that the residual solvent has been reduced to the practical minimum. The limits should be realistic in relation to analytical precision, manufacturing capability, reasonable variation in the manufacturing process, and the limits should reflect contemporary manufacturing standards.

Option 2 may be applied by adding the amounts of a residual solvent present in each of the components of the medicinal product. The sum of the amounts of solvent per day should be less than that given by the PDE.

Consider an example of the use of Option 1 and Option 2 applied to acetonitrile in a medicinal product. The permitted daily exposure to acetonitrile is 4.1 mg per day; thus, the Option 1 limit is 410 ppm. The maximum administered daily mass of a medicinal product is 5.0 g, and the medicinal product contains two excipients. The composition of the medicinal product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in formulation	Acetonitrile content	Daily exposure
Active substance	0.3 g	800 ppm	0.24 mg
Excipient 1	0.9 g	400 ppm	0.36 mg
Excipient 2	3.8 g	800 ppm	3.04 mg
Medicinal product	5.0 g	728 ppm	3.64 mg

Excipient 1 meets the Option 1 limit, but the active substance, excipient 2, and medicinal product do not meet the Option 1 limit. Nevertheless, the product meets the Option 2 limit of 4.1 mg per day and thus conforms to the recommendations in this guideline.

Consider another example using acetonitrile as residual solvent. The maximum administered daily mass of a medicinal product is 5.0 g, and the medicinal product contains two excipients. The composition of the medicinal product and the calculated maximum content of residual acetonitrile is given in the following table.

Component	Amount in formulation	Acetonitrile content	Daily exposure
Active substance	0.3 g	800 ppm	0.24 mg
Excipient 1	0.9 g	2000 ppm	1.80 mg
Excipient 2	3.8 g	800 ppm	3.04 mg
Medicinal product	5.0 g	1016 ppm	5.08 mg

In this example, the product meets neither the Option 1 nor the Option 2 limit according to this summation.

The manufacturer could test the medicinal product to determine if the formulation process reduced the level of acetonitrile. If the level of acetonitrile was not reduced during formulation to the allowed limit, then the manufacturer of the medicinal product should take other steps to reduce the amount of acetonitrile in the medicinal product. If all of these steps fail to reduce the level of residual solvent, in exceptional cases the manufacturer could provide a summary of efforts made to reduce the solvent level to meet the guideline value, and provide a risk-benefit analysis to support allowing the product to be utilised containing residual solvent at a higher level.

3.4 ANALYTICAL PROCEDURES

Residual solvents are typically determined using chromatographic techniques such as gas chromatography. Any harmonised procedures for determining levels of residual solvents as described in the pharmacopoeias should be used, if feasible. Otherwise, manufacturers would be free to select the most appropriate validated analytical procedure for a particular application. If only Class 3 solvents are present, a non-specific method such as loss on drying may be used.

Validation of methods for residual solvents should conform to ICH guidelines "Text on Validation of Analytical Procedures" and "Extension of the ICH Text on Validation of Analytical Procedures".

3.5 REPORTING LEVELS OF RESIDUAL SOLVENTS

Manufacturers of pharmaceutical products need certain information about the content of residual solvents in excipients or active substances in order to meet the criteria of this guideline. The following statements are given as acceptable examples of the information that could be provided from a supplier of excipients or active substances to a pharmaceutical manufacturer. The supplier might choose one of the following as appropriate:

— only Class 3 solvents are likely to be present. Loss on drying is less than 0.5 per cent;
— only Class 2 solvents X, Y, ... are likely to be present. All are below the Option 1 limit;

(Here the supplier would name the Class 2 solvents represented by X, Y, ...)

— only Class 2 solvents X, Y, ... and Class 3 solvents are likely to be present. Residual Class 2 solvents are below the Option 1 limit and residual Class 3 solvents are below 0.5 per cent.

If Class 1 solvents are likely to be present, they should be identified and quantified. "Likely to be present" refers to the solvent used in the final manufacturing step and to solvents that are used in earlier manufacturing steps and not removed consistently by a validated process.

If solvents of Class 2 or Class 3 are present at greater than their Option 1 limits or 0.5 per cent, respectively, they should be identified and quantified.

4 LIMITS OF RESIDUAL SOLVENTS

4.1 SOLVENTS TO BE AVOIDED

Solvents in Class 1 should not be employed in the manufacture of active substances, excipients, and medicinal products because of their unacceptable toxicity or their deleterious environmental effect. However, if their use is unavoidable in order to produce a medicinal product with a significant therapeutic advance, then their levels should be restricted as shown in Table 1, unless otherwise justified. 1,1,1-Trichloroethane is included in Table 1 because it is an environmental hazard. The stated limit of 1500 ppm is based on a review of the safety data.

Table 1. – *Class 1 solvents in pharmaceutical products (solvents that should be avoided)*

Solvent	Concentration limit (ppm)	Concern
Benzene	2	Carcinogen
Carbon tetrachloride	4	Toxic and environmental hazard
1,2-Dichloroethane	5	Toxic
1,1-Dichloroethene	8	Toxic
1,1,1-Trichloroethane	1500	Environmental hazard

4.2 SOLVENTS TO BE LIMITED

Solvents in Table 2 should be limited in pharmaceutical products because of their inherent toxicity. PDEs are given to the nearest 0.1 mg/day, and concentrations are given to the nearest 10 ppm. The stated values do not reflect the necessary analytical precision of determination. Precision should be determined as part of the validation of the method.

Table 2. – *Class 2 solvents in pharmaceutical products*

Solvent	PDE (mg/day)	Concentration limit (ppm)
Acetonitrile	4.1	410
Chlorobenzene	3.6	360
Chloroform	0.6	60
Cumene	0.7	70
Cyclohexane	38.8	3880
1,2-Dichloroethene	18.7	1870
Dichloromethane	6.0	600
1,2-Dimethoxyethane	1.0	100
N,N-Dimethylacetamide	10.9	1090
N,N-Dimethylformamide	8.8	880
1,4-Dioxane	3.8	380
2-Ethoxyethanol	1.6	160
Ethyleneglycol	6.2	620
Formamide	2.2	220
Hexane	2.9	290
Methanol	30.0	3000
2-Methoxyethanol	0.5	50
Methylbutylketone	0.5	50
Methylcyclohexane	11.8	1180
Methylisobutylketone	45.0	4500
N-Methylpyrrolidone	5.3	530
Nitromethane	0.5	50
Pyridine	2.0	200
Sulfolane	1.6	160
Tetrahydrofuran	7.2	720
Tetralin	1.0	100
Toluene	8.9	890
1,1,2-Trichloroethene	0.8	80
Xylene[a]	21.7	2170

[a]usually 60 per cent *m*-xylene, 14 per cent *p*-xylene, 9 per cent *o*-xylene with 17 per cent ethyl benzene.

4.3 SOLVENTS WITH LOW TOXIC POTENTIAL

Solvents in Class 3 (shown in Table 3) may be regarded as less toxic and of lower risk to human health. Class 3 includes no solvent known as a human health hazard at levels normally accepted in pharmaceuticals. However, there are no long-term toxicity or carcinogenicity studies for many of the solvents in Class 3. Available data indicate that they are less toxic in acute or short-term studies and negative in genotoxicity studies. It is considered that amounts of these residual solvents of 50 mg per day or less (corresponding to 5000 ppm or 0.5 per cent under Option 1) would be acceptable without justification. Higher amounts may also be acceptable provided they are realistic in relation to manufacturing capability and good manufacturing practice.

Table 3. – *Class 3 solvents which should be limited by GMP or other quality-based requirements*

Acetic acid	Heptane
Acetone	Isobutyl acetate
Anisole	Isopropyl acetate
1-Butanol	Methyl acetate
2-Butanol	3-Methyl-1-butanol
Butyl acetate	Methylethylketone
tert-Butylmethyl ether	2-Methyl-1-propanol
Dimethyl sulfoxide	Pentane
Ethanol	1-Pentanol
Ethyl acetate	1-Propanol
Ethyl ether	2-Propanol
Ethyl formate	Propyl acetate
Formic acid	Triethylamine

4.4 SOLVENTS FOR WHICH NO ADEQUATE TOXICOLOGICAL DATA WAS FOUND

The following solvents (Table 4) may also be of interest to manufacturers of excipients, active substances, or medicinal products. However, no adequate toxicological data on which to base a PDE was found. Manufacturers should supply justification for residual levels of these solvents in pharmaceutical products.

Table 4. – *Solvents for which no adequate toxicological data was found*

1,1-Diethoxypropane	Methylisopropylketone
1,1-Dimethoxymethane	Methyltetrahydrofuran
2,2-Dimethoxypropane	Petroleum ether
Isooctane	Trichloroacetic acid
Isopropyl ether	Trifluoroacetic acid

GLOSSARY

Genotoxic carcinogens Carcinogens which produce cancer by affecting genes or chromosomes.

LOEL Abbreviation for *lowest-observed effect level.*

Lowest-observed effect level The lowest dose of substance in a study or group of studies that produces biologically significant increases in frequency or severity of any effects in the exposed humans or animals.

Modifying factor A factor determined by professional judgement of a toxicologist and applied to bioassay data to relate that data safely to humans.

Neurotoxicity The ability of a substance to cause adverse effects on the nervous system.

NOEL Abbreviation for *no-observed-effect level.*

No-observed-effect level The highest dose of substance at which there are no biologically significant increases in

frequency or severity of any effects in the exposed humans or animals.

PDE Abbreviation for *permitted daily exposure.*

Permitted daily exposure The maximum acceptable intake per day of residual solvent in pharmaceutical products.

Reversible toxicity The occurrence of harmful effects that are caused by a substance and which disappear after exposure to the substance ends.

Strongly suspected human carcinogen A substance for which there is no epidemiological evidence of carcinogenesis but there are positive genotoxicity data and clear evidence of carcinogenesis in rodents.

Teratogenicity The occurrence of structural malformations in a developing foetus when a substance is administered during pregnancy.

APPENDIX 1. LIST OF SOLVENTS INCLUDED IN THE GUIDELINE

Solvent	Other Names	Structure	Class
Acetic acid	Ethanoic acid	CH_3COOH	Class 3
Acetone	2-Propanone Propan-2-one	CH_3COCH_3	Class 3
Acetonitrile		CH_3CN	Class 2
Anisole	Methoxybenzene		Class 3
Benzene	Benzol		Class 1
1-Butanol	*n*-Butyl alcohol Butan-1-ol	$CH_3[CH_2]_3OH$	Class 3
2-Butanol	*sec*-Butyl alcohol Butan-2-ol	$CH_3CH_2CH(OH)CH_3$	Class 3
Butyl acetate	Acetic acid butyl ester	$CH_3COO[CH_2]_3CH_3$	Class 3
tert-Butylmethyl ether	2-Methoxy-2-methylpropane	$(CH_3)_3COCH_3$	Class 3
Carbon tetrachloride	Tetrachloromethane	CCl_4	Class 1
Chlorobenzene			Class 2
Chloroform	Trichloromethane	$CHCl_3$	Class 2
Cumene	Isopropylbenzene (1-Methylethyl)benzene		Class 2
Cyclohexane	Hexamethylene		Class 2
1,2-Dichloroethane	*sym*-Dichloroethane Ethylene dichloride Ethylene chloride	CH_2ClCH_2Cl	Class 1
1,1-Dichloroethene	1,1-Dichloroethylene Vinylidene chloride	$H_2C=CCl_2$	Class 1
1,2-Dichloroethene	1,2-Dichloroethylene Acetylene dichloride	$ClHC=CHCl$	Class 2
Dichloromethane	Methylene chloride	CH_2Cl_2	Class 2
1,2-Dimethoxyethane	Ethyleneglycol dimethyl ether Monoglyme Dimethyl cellosolve	$H_3COCH_2CH_2OCH_3$	Class 2
N,*N*-Dimethylacetamide	DMA	$CH_3CON(CH_3)_2$	Class 2
N,*N*-Dimethylformamide	DMF	$HCON(CH_3)_2$	Class 2
Dimethyl sulfoxide	Methylsulfinylmethane Methyl sulfoxide DMSO	$(CH_3)_2SO$	Class 3
1,4-Dioxane	*p*-Dioxane [1,4]Dioxane		Class 2
Ethanol	Ethyl alcohol	CH_3CH_2OH	Class 3
2-Ethoxyethanol	Cellosolve	$CH_3CH_2OCH_2CH_2OH$	Class 2
Ethyl acetate	Acetic acid ethyl ester	$CH_3COOCH_2CH_3$	Class 3
Ethyleneglycol	1,2-Dihydroxyethane 1,2-Ethanediol	$HOCH_2CH_2OH$	Class 2
Ethyl ether	Diethyl ether Ethoxyethane 1,1'-Oxybisethane	$CH_3CH_2OCH_2CH_3$	Class 3
Ethyl formate	Formic acid ethyl ester	$HCOOCH_2CH_3$	Class 3
Formamide	Methanamide	$HCONH_2$	Class 2
Formic acid		$HCOOH$	Class 3
Heptane	*n*-Heptane	$CH_3[CH_2]_5CH_3$	Class 3
Hexane	*n*-Hexane	$CH_3[CH_2]_4CH_3$	Class 2
Isobutyl acetate	Acetic acid isobutyl ester	$CH_3COOCH_2CH(CH_3)_2$	Class 3
Isopropyl acetate	Acetic acid isopropyl ester	$CH_3COOCH(CH_3)_2$	Class 3
Methanol	Methyl alcohol	CH_3OH	Class 2
2-Methoxyethanol	Methyl cellosolve	$CH_3OCH_2CH_2OH$	Class 2
Methyl acetate	Acetic acid methyl ester	CH_3COOCH_3	Class 3

Solvent	Other Names	Structure	Class
3-Methyl-1-butanol	Isoamyl alcohol Isopentyl alcohol 3-Methylbutan-1-ol	$(CH_3)_2CHCH_2CH_2OH$	Class 3
Methylbutylketone	2-Hexanone Hexan-2-one	$CH_3[CH_2]_3COCH_3$	Class 2
Methylcyclohexane	Cyclohexylmethane		Class 2
Methylethylketone	2-Butanone MEK Butan-2-one	$CH_3CH_2COCH_3$	Class 3
Methylisobutylketone	4-Methylpentan-2-one 4-Methyl-2-pentanone MIBK	$CH_3COCH_2CH(CH_3)_2$	Class 2
2-Methyl-1-propanol	Isobutyl alcohol 2-Methylpropan-1-ol	$(CH_3)_2CHCH_2OH$	Class 3
N-Methylpyrrolidone	1-Methylpyrrolidin-2-one 1-Methyl-2-pyrrolidinone		Class 2
Nitromethane		CH_3NO_2	Class 2
Pentane	*n*-Pentane	$CH_3[CH_2]_3CH_3$	Class 3
1-Pentanol	Amyl alcohol Pentan-1-ol Pentyl alcohol	$CH_3[CH_2]_3CH_2OH$	Class 3
1-Propanol	Propan-1-ol Propyl alcohol	$CH_3CH_2CH_2OH$	Class 3
2-Propanol	Propan-2-ol Isopropyl alcohol	$(CH_3)_2CHOH$	Class 3
Propyl acetate	Acetic acid propyl ester	$CH_3COOCH_2CH_2CH_3$	Class 3
Pyridine			Class 2
Sulfonane	Tetrahydrothiophene 1,1-dioxide		Class 2
Tetrahydrofuran	Tetramethylene oxide Oxacyclopentane		Class 2
Tetralin	1,2,3,4-Tetrahydronaphthalene		Class 2
Toluene	Methylbenzene		Class 2
1,1,1-Trichloroethane	Methylchloroform	CH_3CCl_3	Class 1
1,1,2-Trichloroethene	Trichloroethene	$HClC{=}CCl_2$	Class 2
Triethylamine	*N*,*N*-Diethylethanamine	$N(CH_2CH_3)_3$	Class 3
Xylene*	Dimethybenzene Xylol		Class 2

*usually 60 per cent *m*-xylene, 14 per cent *p*-xylene, 9 per cent *o*-xylene with 17 per cent ethyl benzene.

APPENDIX 2. ADDITIONAL BACKGROUND

A2.1 ENVIRONMENTAL REGULATION OF ORGANIC VOLATILE SOLVENTS

Several of the residual solvents frequently used in the production of pharmaceuticals are listed as toxic chemicals in Environmental Health Criteria (EHC) monographs and the Integrated Risk Information System (IRIS). The objectives of such groups as the International Programme on Chemical Safety (IPCS), the United States Environmental Protection Agency (USEPA) and the United States Food and Drug Administration (USFDA) include the determination of acceptable exposure levels. The goal is protection of human health and maintenance of environmental integrity against the possible deleterious effects of chemicals resulting from long-term environmental exposure. The methods involved in the estimation of maximum safe exposure limits are usually based on long-term studies. When long-term study data are unavailable, shorter term study data can be used with modification of the approach such as use of larger safety factors. The approach described therein relates primarily to long-term or life-time exposure of the general population in the ambient environment, i.e. ambient air, food, drinking water and other media.

A2.2 RESIDUAL SOLVENTS IN PHARMACEUTICALS

Exposure limits in this guideline are established by referring to methodologies and toxicity data described in EHC and IRIS monographs. However, some specific assumptions about residual solvents to be used in the synthesis and

formulation of pharmaceutical products should be taken into account in establishing exposure limits. They are:

1) Patients (not the general population) use pharmaceuticals to treat their diseases or for prophylaxis to prevent infection or disease.

2) The assumption of life-time patient exposure is not necessary for most pharmaceutical products but may be appropriate as a working hypothesis to reduce risk to human health.

3) Residual solvents are unavoidable components in pharmaceutical production and will often be a part of medicinal products.

4) Residual solvents should not exceed recommended levels except in exceptional circumstances.

5) Data from toxicological studies that are used to determine acceptable levels for residual solvents should have been generated using appropriate protocols such as those described for example, by OECD, EPA, and the FDA Red Book.

APPENDIX 3. METHODS FOR ESTABLISHING EXPOSURE LIMITS

The Gaylor-Kodell method of risk assessment (Gaylor, D. W. and Kodell, R. L. Linear Interpolation algorithm for low dose assessment of toxic substance. J. Environ. Pathology, 4, 305, 1980) is appropriate for Class 1 carcinogenic solvents. Only in cases where reliable carcinogenicity data are available should extrapolation by the use of mathematical models be applied to setting exposure limits. Exposure limits for Class 1 solvents could be determined with the use of a large safety factor (i.e., 10 000 to 100 000) with respect to the no-observed-effect level (NOEL). Detection and quantification of these solvents should be by state-of-the-art analytical techniques.

Acceptable exposure levels in this guideline for Class 2 solvents were established by calculation of PDE values according to the procedures for setting exposure limits in pharmaceuticals (*Pharmacopeial Forum*, Nov-Dec 1989), and the method adopted by IPCS for Assessing Human Health Risk of Chemicals (*Environmental Health Criteria 170*, WHO, 1994). These methods are similar to those used by the USEPA (IRIS) and the USFDA (*Red Book*) and others. The method is outlined here to give a better understanding of the origin of the PDE values. It is not necessary to perform these calculations in order to use the PDE values tabulated in Section 4 of this document.

PDE is derived from the no-observed-effect level (NOEL), or the lowest-observed effect level (LOEL), in the most relevant animal study as follows:

$$\text{PDE} = \frac{\text{NOEL} \times \text{Weight Adjustment}}{\text{F1} \times \text{F2} \times \text{F3} \times \text{F4} \times \text{F5}}$$

The PDE is derived preferably from a NOEL. If no NOEL is obtained, the LOEL may be used. Modifying factors proposed here, for relating the data to humans, are the same kind of "uncertainty factors" used in Environmental Health Criteria (*Environmental Health Criteria* 170, World Health Organization, Geneva, 1994), and "modifying factors" or "safety factors" in *Pharmacopoeial Forum*. The assumption of 100 per cent systemic exposure is used in all calculations regardless of route of administration.

The modifying factors are as follows:

F1 = a factor to account for extrapolation between species:

- F1 = 2 for extrapolation from dogs to humans;
- F1 = 2.5 for extrapolation from rabbits to humans;
- F1 = 3 for extrapolation from monkeys to humans;
- F1 = 5 for extrapolation from rats to humans;
- F1 = 10 for extrapolation from other animals to humans;
- F1 = 12 for extrapolation from mice to humans.

F1 takes into account the comparative surface area: body weight ratios for the species concerned and for man. Surface area (S) is calculated as:

$$S = km^{0.67}$$

in which m = body mass, and the constant k has been taken to be 10. The body weight used in the equation are those shown below in Table A3.-1.

Table A3.-1. – *Values used in the calculations in this document*

Rat body weight	425 g
Pregnant rat body weight	330 g
Mouse body weight	28 g
Pregnant mouse body weight	30 g
Guinea-pig body weight	500 g
Rhesus monkey body weight	2.5 kg
Rabbit body weight (pregnant or not)	4 kg
Beagle dog body weight	11.5 kg
Rat respiratory volume	290 L/day
Mouse respiratory volume	43 L/day
Rabbit respiratory volume	1440 L/day
Guinea-pig respiratory volume	430 L/day
Human respiratory volume	28800 L/day
Dog respiratory volume	9000 L/day
Monkey respiratory volume	1150 L/day
Mouse water consumption	5 mL/day
Rat water consumption	30 mL/day
Rat food consumption	30 g/day

F2 = a factor of 10 to account for variability between individuals. A factor of 10 is generally given for all organic solvents, and 10 is used consistently in this guideline.

F3 = a variable factor to account for toxicity studies of short-term exposure:

- F3 = 1 for studies that last at least one half-lifetime (1 year for rodents or rabbits; 7 years for cats, dogs and monkeys);
- F3 = 1 for reproductive studies in which the whole period of organogenesis is covered;
- F3 = 2 for a 6 month study in rodents, or a 3.5 year study in non-rodents;
- F3 = 5 for a 3 month study in rodents, or a 2 year study in non-rodents;
- F3 = 10 for studies of a shorter duration.

In all cases, the higher factor has been used for study durations between the time points, e.g. a factor of 2 for a 9 month rodent study.

F4 = a factor that may be applied in cases of severe toxicity, e.g. non-genotoxic carcinogenicity, neurotoxicity or teratogenicity. In studies of reproductive toxicity, the following factors are used:

- F4 = 1 for foetal toxicity associated with maternal toxicity;
- F4 = 5 for foetal toxicity without maternal toxicity;
- F4 = 5 for a teratogenic effect with maternal toxicity;
- F4 = 10 for a teratogenic effect without maternal toxicity.

F5 = a variable factor that may be applied if the no-effect level was not established.

When only a LOEL is available, a factor of up to 10 can be used depending on the severity of the toxicity.

The weight adjustment assumes an arbitrary adult human body weight for either sex of 50 kg. This relatively low weight provides an additional safety factor against the standard weights of 60 kg or 70 kg that are often used in this type of calculation. It is recognised that some adult patients weigh less than 50 kg; these patients are considered to be accommodated by the built-in safety factors used to determine a PDE. If the solvent was present in a formulation specifically intended for paediatric use, an adjustment for a lower body weight would be appropriate.

As an example of the application of this equation, consider the toxicity study of acetonitrile in mice that is summarised in *Pharmeuropa*, Vol. 9. No. 1, Supplement, April 1997, page S24. The NOEL is calculated to be 50.7 mg kg^{-1} day^{-1}. The PDE for acetonitrile in this study is calculated as follows:

$$\text{PDE} = \frac{50.7\text{mg kg}^{-1}\ \text{day}^{-1} \times 50\ \text{kg}}{12 \times 10 \times 5 \times 1 \times 1} = 4.22\ \text{mg day}^{-1}$$

In this example,

F1	=	12 to account for the extrapolation from mice to humans;
F2	=	10 to account for differences between individual humans;
F3	=	5 because the duration of the study was only 13 weeks;
F4	=	1 because no severe toxicity was encountered;
F5	=	1 because the no-effect level was determined.

The equation for an ideal gas, $PV = nRT$, is used to convert concentrations of gases used in inhalation studies from units of ppm to units of mg/L or mg/m^3. Consider as an example the rat reproductive toxicity study by inhalation of carbon tetrachloride (molecular weight 153.84) summarised in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997, page S9.

$$\frac{n}{V} = \frac{P}{RT} = \frac{300 \times 10^{-6}\ \text{atm} \times 153\ 840\ \text{mg mol}^{-1}}{0.082\ \text{L atm K}^{-1}\text{mol}^{-1} \times 298\ \text{K}} = \frac{46.15\ \text{mg}}{24.45\ \text{L}}$$

$$= 1.89\ \text{mg/L}$$

The relationship 1000 L = 1 m^3 is used to convert to mg/m^3.

E. Alcoholimetric Tables

(Ph. Eur. general texts 5.5)

The general formula agreed by the Council of the European Communities in its Directive of 27 July 1976 on alcoholimetry served as the basis for establishing the following tables.

% *V/V*	% *m/m*	ρ_{20} (kg/m^3)
0.0	0.0	998.20
0.1	0.08	998.05
0.2	0.16	997.90
0.3	0.24	997.75
0.4	0.32	997.59
0.5	0.40	997.44
0.6	0.47	997.29
0.7	0.55	997.14

F. Pharmacopoeial Harmonisation

(Ph. Eur. general texts 5.8)

This general chapter is included for guidance of users.

The chapter does not affect in any way the status of the monographs and general chapters as the authoritative reference in case of doubt or dispute, where compliance with the European Pharmacopoeia is required.

The European Pharmacopoeia Commission recognises the utility of working with other pharmacopoeial bodies to develop harmonised monographs and general chapters. Such harmonisation is fully compatible with the declared aims of the Commission and has benefits of different kinds, notably the simplification and rationalisation of quality control methods and licensing procedures. Such harmonisation also enhances the benefits of the work of the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) and the International Cooperation on Harmonisation of Technical Requirements for Registration of Veterinary Medicinal Products (VICH), since some of the guidelines developed depend on pharmacopoeial general chapters for their application.

Work on harmonisation is carried out by a well-defined but informal process in the Pharmacopoeial Discussion Group (PDG), in which the European Pharmacopoeia, the Japanese Pharmacopoeia and the United States Pharmacopeia are associated. Pharmacopoeial harmonisation has the following 2 aims:

- for general chapters, the aim is to arrive at interchangeable methods or requirements so that demonstration of compliance using a general chapter from one of the 3 pharmacopoeias implies that the same result would be obtained using the general chapter of either of the other pharmacopoeias; when a formal declaration of interchangeability has been recommended by ICH, the corresponding information is available on the ICH website;
- for monographs, the aim is to arrive at identical requirements for all attributes of a substance; for most substances it can be extremely difficult to achieve complete harmonisation, for example because of differences in legal status and interpretation; it has therefore appeared worthwhile to the PDG to approve and publish monographs in which as many attributes as possible are harmonised.

Any non-harmonised attributes/provisions and any local requirements (i.e. attributes/provisions that are present only in the Ph. Eur. text) are indicated in the relevant Ph. Eur. general chapters and monographs: the non-harmonised attributes/provisions are placed between black diamonds (♦♦), while the local requirements are placed between white diamonds (◊◊).

The non-mandatory Functionality-related characteristics section is specific to the Ph. Eur.; it is not subject to pharmacopoeial harmonisation and is therefore not placed between black or white diamonds.

Harmonisation is not achieved until the text becomes official in all 3 pharmacopoeias.

It remains the ultimate responsibility of the user to verify the current content of the texts in force in the respective pharmacopoeias.

The 3 pharmacopoeias have undertaken not to make unilateral changes to harmonised monographs and general chapters but rather to apply the agreed revision procedure whereby all partners adopt a revision simultaneously.

G. Statistical Analysis of Results of Biological Assays and Tests

(Ph. Eur. general text 5.3)

1. INTRODUCTION

This chapter provides guidance for the design of bioassays prescribed in the European Pharmacopoeia (Ph. Eur.) and for analysis of their results. It is intended for use by those whose primary training and responsibilities are not in statistics, but who have responsibility for analysis or interpretation of the results of these assays, often without the help and advice of a statistician. The methods of calculation described in this annex are not mandatory for the bioassays which themselves constitute a mandatory part of the Ph. Eur. Alternative methods can be used and may be accepted by the competent authorities, provided that they are supported by relevant data and justified during the assay validation process. A wide range of computer software is available and may be useful depending on the facilities available to, and the expertise of, the analyst.

Professional advice should be obtained in situations where: a comprehensive treatment of design and analysis suitable for research or development of new products is required; the restrictions imposed on the assay design by this chapter are not satisfied, for example particular laboratory constraints may require customized assay designs, or equal numbers of equally spaced doses may not be suitable; analysis is required for extended non-linear dose-response curves, for example as may be encountered in immunoassays. An outline of extended dose-response curve analysis for one widely used model is nevertheless included in Section 3.4 and a simple example is given in Section 5.4.

1.1. GENERAL DESIGN AND PRECISION

Biological methods are described for the assay of certain substances and preparations whose potency cannot be adequately assured by chemical or physical analysis.

The principle applied wherever possible throughout these assays is that of comparison with a standard preparation so as to determine how much of the substance to be examined produces the same biological effect as a given quantity, the *Unit*, of the standard preparation. It is an essential condition of such methods of biological assay that the tests on the standard preparation and on the substance to be examined be carried out at the same time and under identical conditions.

For certain assays (determination of virus titre for example) the potency of the test sample is not expressed relative to a standard. This type of assay is dealt with in Section 4.5.

Any estimate of potency derived from a biological assay is subject to random error due to the inherent variability of biological responses and calculations of error should be made, if possible, from the results of each assay, even when the official method of assay is used. Methods for the design of assays and the calculation of their errors are, therefore, described below. In every case, before a statistical method is adopted, a preliminary test is to be carried out with an appropriate number of assays, in order to ascertain the applicability of this method.

The confidence interval for the potency gives an indication of the precision with which the potency has been estimated in the assay. It is calculated with due regard to the experimental design and the sample size. The 95 per cent confidence interval is usually chosen in biological assays. Mathematical statistical methods are used to calculate these limits so as to

warrant the statement that there is a 95 per cent probability that these limits include the true potency. Whether this precision is acceptable to the European Pharmacopoeia depends on the requirements set in the monograph for the preparation concerned.

The terms "mean" and "standard deviation" are used here as defined in most current textbooks of biometry.

The terms "stated potency" or "labelled potency", "assigned potency", "assumed potency", "potency ratio" and "estimated potency" are used in this section to indicate the following concepts:

— "stated potency" or "labelled potency": in the case of a formulated product a nominal value assigned from knowledge of the potency of the bulk material; in the case of bulk material the potency estimated by the manufacturer;
— "assigned potency": the potency of the standard preparation;
— "assumed potency": the provisionally assigned potency of a preparation to be examined which forms the basis of calculating the doses that would be equipotent with the doses to be used of the standard preparation;
— "potency ratio" of an unknown preparation; the ratio of equipotent doses of the standard preparation and the unknown preparation under the conditions of the assay;
— "estimated potency": the potency calculated from assay data.

Section 9 (Glossary of symbols) is a tabulation of the more important uses of symbols throughout this annex. Where the text refers to a symbol not shown in this section or uses a symbol to denote a different concept, this is defined in that part of the text.

2. RANDOMISATION AND INDEPENDENCE OF INDIVIDUAL TREATMENTS

The allocation of the different treatments to different experimental units (animals, tubes, etc.) should be made by some strictly random process. Any other choice of experimental conditions that is not deliberately allowed for in the experimental design should also be made randomly. Examples are the choice of positions for cages in a laboratory and the order in which treatments are administered.

In particular, a group of animals receiving the same dose of any preparation should not be treated together (at the same time or in the same position) unless there is strong evidence that the relevant source of variation (for example, between times, or between positions) is negligible. Random allocations may be obtained from computers by using the built-in randomisation function. The analyst must check whether a different series of numbers is produced every time the function is started.

The preparations allocated to each experimental unit should be as independent as possible. Within each experimental group, the dilutions allocated to each treatment are not normally divisions of the same dose, but should be prepared individually. Without this precaution, the variability inherent in the preparation will not be fully represented in the experimental error variance. The result will be an under-estimation of the residual error leading to:

1) an unjustified increase in the stringency of the test for the analysis of variance (see Sections 3.2.3 and 3.2.4),

2) an under-estimation of the true confidence limits for the test, which, as shown in Section 3.2.5, are calculated from the estimate of s^2, the residual error mean square.

3. ASSAYS DEPENDING UPON QUANTITATIVE RESPONSES

3.1. STATISTICAL MODELS

3.1.1. GENERAL PRINCIPLES

The bioassays included in the Ph. Eur. have been conceived as "dilution assays", which means that the unknown preparation to be assayed is supposed to contain the same active principle as the standard preparation, but in a different ratio of active and inert components. In such a case the unknown preparation may in theory be derived from the standard preparation by dilution with inert components.

To check whether any particular assay may be regarded as a dilution assay, it is necessary to compare the dose-response relationships of the standard and unknown preparations. If these dose-response relationships differ significantly, then the theoretical dilution assay model is not valid. Significant differences in the dose-response relationships for the standard and unknown preparations may suggest that one of the preparations contains, in addition to the active principle, other components which are not inert but which influence the measured responses.

To make the effect of dilution in the theoretical model apparent, it is useful to transform the dose-response relationship to a linear function on the widest possible range of doses. 2 statistical models are of interest as models for the bioassays prescribed: the parallel-line model and the slope-ratio model.

The application of either is dependent on the fulfilment of the following conditions:

1) the different treatments have been randomly assigned to the experimental units,

2) the responses to each treatment are normally distributed,

3) the standard deviations of the responses within each treatment group of both standard and unknown preparations do not differ significantly from one another.

When an assay is being developed for use, the analyst has to determine that the data collected from many assays meet these theoretical conditions.

— Condition 1 can be fulfilled by an efficient use of Section 2.
— Condition 2 is an assumption which in practice is almost always fulfilled. Minor deviations from this assumption will in general not introduce serious flaws in the analysis as long as several replicates per treatment are included. In case of doubt, a test for deviations from normality (e.g. the Shapiro-Wilk[1] test) may be performed.
— Condition 3 can be checked with a test for homogeneity of variances (e.g. Bartlett's[2] test, Cochran's[3] test). Inspection of graphical representations of the data can also be very instructive for this purpose (see examples in Section 5).

When conditions 2 and/or 3 are not met, a transformation of the responses may bring a better fulfilment of these conditions. Examples are $\ln y$, $\sqrt{y}$, y^2.

— Logarithmic transformation of the responses y to $\ln y$ can be useful when the homogeneity of variances is not satisfactory. It can also improve the normality if the distribution is skewed to the right.

[1] *Wilk, M.B. and Shapiro, S.S. (1968). The joint assessment of normality of several independent samples, Technometrics 10, 825-839.*
[2] *Bartlett, M.S. (1937). Properties of sufficiency and statistical tests, Proc. Roy. Soc. London, Series A 160, 280-282.*
[3] *Cochran, W.G. (1951). Testing a linear relation among variances, Biometrics 7, 17-32.*

— The transformation of y to $\sqrt{y}$ is useful when the observations follow a Poisson distribution i.e. when they are obtained by counting.
— The square transformation of y to y^2 can be useful if, for example, the dose is more likely to be proportional to the area of an inhibition zone rather than the measured diameter of that zone.

For some assays depending on quantitative responses, such as immunoassays or cell-based *in vitro* assays, a large number of doses is used. These doses give responses that completely span the possible response range and produce an extended non-linear dose-response curve. Such curves are typical for all bioassays, but for many assays the use of a large number of doses is not ethical (for example, *in vivo* assays) or practical, and the aims of the assay may be achieved with a limited number of doses. It is therefore customary to restrict doses to that part of the dose-response range which is linear under suitable transformation, so that the methods of Sections 3.2 or 3.3 apply. However, in some cases analysis of extended dose-response curves may be desirable. An outline of one model which may be used for such analysis is given in Section 3.4 and a simple example is shown in Section 5.4.

There is another category of assays in which the response cannot be measured in each experimental unit, but in which only the fraction of units responding to each treatment can be counted. This category is dealt with in Section 4.

3.1.2. ROUTINE ASSAYS

When an assay is in routine use, it is seldom possible to check systematically for conditions 1 to 3, because the limited number of observations per assay is likely to influence the sensitivity of the statistical tests. Fortunately, statisticians have shown that, in symmetrical balanced assays, small deviations from homogeneity of variance and normality do not seriously affect the assay results. The applicability of the statistical model needs to be questioned only if a series of assays shows doubtful validity. It may then be necessary to perform a new series of preliminary investigations as discussed in Section 3.1.1.

Two other necessary conditions depend on the statistical model to be used:

— for the parallel-line model:

4A) the relationship between the logarithm of the dose and the response can be represented by a straight line over the range of doses used,

5A) for any unknown preparation in the assay the straight line is parallel to that for the standard.

— for the slope-ratio model:

4B) the relationship between the dose and the response can be represented by a straight line for each preparation in the assay over the range of doses used,

5B) for any unknown preparation in the assay the straight line intersects the y-axis (at zero dose) at the same point as the straight line of the standard preparation (i.e. the response functions of all preparations in the assay must have the same intercept as the response function of the standard).

Conditions 4A and 4B can be verified only in assays in which at least 3 dilutions of each preparation have been tested. The use of an assay with only 1 or 2 dilutions may be justified when experience has shown that linearity and parallelism or equal intercept are regularly fulfilled.

After having collected the results of an assay, and before calculating the relative potency of each test sample, an analysis of variance is performed, in order to check whether conditions 4A and 5A (or 4B and 5B) are fulfilled. For this, the total sum of squares is subdivided into a certain number of sum of squares corresponding to each condition which has to be fulfilled. The remaining sum of squares represents the residual experimental error to which the absence or existence of the relevant sources of variation can be compared by a series of F-ratios.

When validity is established, the potency of each unknown relative to the standard may be calculated and expressed as a potency ratio or converted to some unit relevant to the preparation under test e.g. an International Unit. Confidence limits may also be estimated from each set of assay data.

Assays based on the parallel-line model are discussed in Section 3.2 and those based on the slope-ratio model in Section 3.3.

If any of the 5 conditions (1, 2, 3, 4A, 5A or 1, 2, 3, 4B, 5B) are not fulfilled, the methods of calculation described here are invalid and an investigation of the assay technique should be made.

The analyst should not adopt another transformation unless it is shown that non-fulfilment of the requirements is not incidental but is due to a systematic change in the experimental conditions. In this case, testing as described in Section 3.1.1 should be repeated before a new transformation is adopted for the routine assays.

Excess numbers of invalid assays due to non-parallelism or non-linearity, in a routine assay carried out to compare similar materials, are likely to reflect assay designs with inadequate replication. This inadequacy commonly results from incomplete recognition of all sources of variability affecting the assay, which can result in underestimation of the residual error leading to large F-ratios.

It is not always feasible to take account of all possible sources of variation within one single assay (e.g. day-to-day variation). In such a case, the confidence intervals from repeated assays on the same sample may not satisfactorily overlap, and care should be exercised in the interpretation of the individual confidence intervals. In order to obtain a more reliable estimate of the confidence interval it may be necessary to perform several independent assays and to combine these into one single potency estimate and confidence interval (see Section 6).

For the purpose of quality control of routine assays it is recommended to keep record of the estimates of the slope of regression and of the estimate of the residual error in control charts.

— An exceptionally high residual error may indicate some technical problem. This should be investigated and, if it can be made evident that something went wrong during the assay procedure, the assay should be repeated.
  An unusually high residual error may also indicate the presence of an occasional outlying or aberrant observation. A response that is questionable because of failure to comply with the procedure during the course of an assay is rejected. If an aberrant value is discovered after the responses have been recorded, but can then be traced to assay irregularities, omission may be justified.
  The arbitrary rejection or retention of an apparently aberrant response can be a serious source of bias.
  In general, the rejection of observations solely because a test for outliers is significant, is discouraged.
— An exceptionally low residual error may once in a while occur and cause the F-ratios to exceed the critical values. In such a case it may be justified to replace the residual error estimated from the individual assay, by an average residual error based on historical data recorded in the control charts.

3.1.3. CALCULATIONS AND RESTRICTIONS

According to general principles of good design the following 3 restrictions are normally imposed on the assay design. They have advantages both for ease of computation and for precision.

a) Each preparation in the assay must be tested with the same number of dilutions.

b) In the parallel-line model, the ratio of adjacent doses must be constant for all treatments in the assay; in the slope-ratio model, the interval between adjacent doses must be constant for all treatments in the assay.

c) There must be an equal number of experimental units to each treatment.

If a design is used which meets these restrictions, the calculations are simple. The formulae are given in Sections 3.2 and 3.3. It is recommended to use software which has been developed for this special purpose. There are several programs in existence which can easily deal with all assay-designs described in the monographs. Not all programs may use the same formulae and algorithms, but they should all lead to the same results.

Assay designs not meeting the above mentioned restrictions may be both possible and correct, but the necessary formulae are too complicated to describe in this text. A brief description of methods for calculation is given in Section 7.1. These methods can also be used for the restricted designs, in which case they are equivalent with the simple formulae.

The formulae for the restricted designs given in this text may be used, for example, to create *ad hoc* programs in a spreadsheet. The examples in Section 5 can be used to clarify the statistics and to check whether such a program gives correct results.

3.2. THE PARALLEL-LINE MODEL

3.2.1. INTRODUCTION

The parallel-line model is illustrated in Figure 3.2.1.-I. The logarithm of the doses are represented on the horizontal axis with the lowest concentration on the left and the highest concentration on the right. The responses are indicated on the vertical axis. The individual responses to each treatment are indicated with black dots. The 2 lines are the calculated ln(dose)-response relationship for the standard and the unknown.

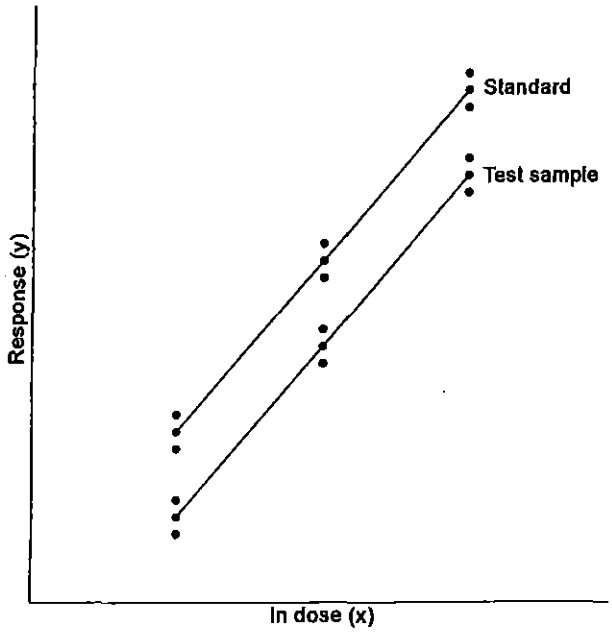

Figure 3.2.1.-I. – *The parallel-line model for a 3 + 3 assay*

Note The natural logarithm (ln or $\log_e$) is used throughout this text. Wherever the term "antilogarithm" is used, the quantity e^x is meant. However, the Briggs or "common" logarithm (log or $\log_{10}$) can equally well be used. In this case the corresponding antilogarithm is 10^x.

For a satisfactory assay the assumed potency of the test sample must be close to the true potency. On the basis of this assumed potency and the assigned potency of the standard, equipotent dilutions (if feasible) are prepared, i.e. corresponding doses of standard and unknown are expected to give the same response. If no information on the assumed potency is available, preliminary assays are carried out over a wide range of doses to determine the range where the curve is linear.

The more nearly correct the assumed potency of the unknown, the closer the 2 lines will be together, for they should give equal responses at equal doses. The horizontal distance between the lines represents the "true" potency of the unknown, relative to its assumed potency. The greater the distance between the 2 lines, the poorer the assumed potency of the unknown. If the line of the unknown is situated to the right of the standard, the assumed potency was overestimated, and the calculations will indicate an estimated potency lower than the assumed potency. Similarly, if the line of the unknown is situated to the left of the standard, the assumed potency was underestimated, and the calculations will indicate an estimated potency higher than the assumed potency.

3.2.2. ASSAY DESIGN

The following considerations will be useful in optimising the precision of the assay design:

1) the ratio between the slope and the residual error should be as large as possible,

2) the range of doses should be as large as possible,

3) the lines should be as close together as possible,

i.e. the assumed potency should be a good estimate of the true potency.

The allocation of experimental units (animals, tubes, etc.) to different treatments may be made in various ways.

3.2.2.1. Completely randomised design

If the totality of experimental units appears to be reasonably homogeneous with no indication that variability in response will be smaller within certain recognisable sub-groups, the allocation of the units to the different treatments should be made randomly.

If units in sub-groups such as physical positions or experimental days are likely to be more homogeneous than the totality of the units, the precision of the assay may be increased by introducing one or more restrictions into the design. A careful distribution of the units over these restrictions permits irrelevant sources of variation to be eliminated.

3.2.2.2. Randomised block design

In this design it is possible to segregate an identifiable source of variation, such as the sensitivity variation between litters of experimental animals or the variation between Petri dishes in a diffusion microbiological assay. The design requires that every treatment be applied an equal number of times in every block (litter or Petri dish) and is suitable only when the block is large enough to accommodate all treatments once. This is illustrated in Section 5.1.3. It is also possible to use a randomised design with repetitions. The treatments should be allocated randomly within each block. An algorithm to obtain random permutations is given in Section 8.5.

3.2.2.3. Latin square design

This design is appropriate when the response may be affected by two different sources of variation each of which can assume k different levels or positions. For example, in a plate assay of an antibiotic the treatments may be arranged in a $k \times k$ array on a large plate, each treatment occurring once in each row and each column. The design is suitable when the number of rows, the number of columns and the number of treatments are equal. Responses are recorded in a square format known as a Latin square. Variations due to differences in response among the k rows and among the k columns may be segregated, thus reducing the error. An example of a Latin square design is given in Section 5.1.2. An algorithm to obtain Latin squares is given in Section 8.6. More complex designs in which one or more treatments are replicated within the Latin square may be useful in some circumstances. The simplified formulae given in this Chapter are not appropriate for such designs, and professional advice should be obtained.

3.2.2.4. Cross-over design

This design is useful when the experiment can be sub-divided into blocks but it is possible to apply only 2 treatments to each block. For example, a block may be a single unit that can be tested on 2 occasions. The design is intended to increase precision by eliminating the effects of differences between units while balancing the effect of any difference between general levels of response at the 2 occasions. If 2 doses of a standard and of an unknown preparation are tested, this is known as a twin cross-over test.

The experiment is divided into 2 parts separated by a suitable time interval. Units are divided into 4 groups and each group receives 1 of the 4 treatments in the first part of the test. Units that received one preparation in the first part of the test receive the other preparation on the second occasion, and units receiving small doses in one part of the test receive large doses in the other. The arrangement of doses is shown in Table 3.2.2.-I. An example can be found in Section 5.1.5.

Table 3.2.2.-I. – *Arrangement of doses in cross-over design*

Group of units	Time I	Time II
1	S_1	T_2
2	S_2	T_1
3	T_1	S_2
4	T_2	S_1

3.2.3. ANALYSIS OF VARIANCE

This section gives formulae that are required to carry out the analysis of variance and will be more easily understood by reference to the worked examples in Section 5.1. Reference should also be made to the glossary of symbols (Section 9).

The formulae are appropriate for symmetrical assays where one or more preparations to be examined (T, U, etc.) are compared with a standard preparation (S). It is stressed that the formulae can only be used if the doses are equally spaced, if equal numbers of treatments per preparation are applied, and each treatment is applied an equal number of times. It should not be attempted to use the formulae in any other situation.

Apart from some adjustments to the error term, the basic analysis of data derived from an assay is the same for completely randomised, randomised block and Latin square designs. The formulae for cross-over tests do not entirely fit this scheme and these are incorporated into Example 5.1.5.

Having considered the points discussed in Section 3.1 and transformed the responses, if necessary, the values should be averaged over each treatment and each preparation, as shown in Table 3.2.3.-I. The linear contrasts, which relate to the slopes of the ln(dose)-response lines, should also be formed. 3 additional formulae, which are necessary for the construction of the analysis of variance, are shown in Table 3.2.3.-II.

The total variation in response caused by the different treatments is now partitioned as shown in Table 3.2.3.-III the sums of squares being derived from the values obtained in Tables 3.2.3.-I and 3.2.3.-II. The sum of squares due to non-linearity can only be calculated if at least 3 doses per preparation are included in the assay.

The residual error of the assay is obtained by subtracting the variations allowed for in the design from the total variation in response (Table 3.2.3.-IV). In this table $\bar{y}$ represents the mean of all responses recorded in the assay. It should be noted that for a Latin square the number of replicate responses (n) is equal to the number of rows, columns or treatments (dh).

The analysis of variance is now completed as follows. Each sum of squares is divided by the corresponding number of degrees of freedom to give mean squares. The mean square for each variable to be tested is now expressed as a ratio to the residual error (s^2) and the significance of these values (known as F-ratios) are assessed by use of Table 8.1 or a suitable sub-routine of a computer program.

3.2.4. TESTS OF VALIDITY

Assay results are said to be "statistically valid" if the outcome of the analysis of variance is as follows.

1) The linear regression term is significant, i.e. the calculated probability is less than 0.05. If this criterion is not met, it is not possible to calculate 95 per cent confidence limits.

2) The term for non-parallelism is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 5A, Section 3.1, is satisfied.

3) The term for non-linearity is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 4A, Section 3.1, is satisfied.

A significant deviation from parallelism in a multiple assay may be due to the inclusion in the assay-design of a preparation to be examined that gives an ln(dose)-response line with a slope different from those for the other preparations. Instead of declaring the whole assay invalid, it may then be decided to eliminate all data relating to that preparation and to restart the analysis from the beginning.

When statistical validity is established, potencies and confidence limits may be estimated by the methods described in the next section.

3.2.5. ESTIMATION OF POTENCY AND CONFIDENCE LIMITS

If I is the ln of the ratio between adjacent doses of any preparation, the common slope (b) for assays with d doses of each preparation is obtained from:

$$b = \frac{H_L(L_S + L_T + \ldots)}{Inh} \qquad (3.2.5.\text{-}1)$$

and the logarithm of the potency ratio of a test preparation, for example T, is:

$$M'_T = \frac{P_T - P_S}{db} \qquad (3.2.5.\text{-}2)$$

Table 3.2.3.-I. – *Formulae for parallel-line assays with d doses of each preparation*

	Standard (*S*)	1st Test sample (*T*)	2nd Test sample (*U*, etc.)
Mean response lowest dose	S_1	T_1	U_1
Mean response 2nd dose	S_2	T_2	U_2
...	...	...	...
Mean response highest dose	S_d	T_d	U_d
Total preparation	$P_S = S_1 + S_2 + ... + S_d$	$P_T = T_1 + T_2 + ... + T_d$	P_U = ...etc.
Linear contrast	$L_S = 1S_1 + 2S_2 + ... + dS_d - \frac{1}{2}(d+1)P_S$	$L_T = 1T_1 + 2T_2 + ... + dT_d - \frac{1}{2}(d+1)P_T$	L_U = ...etc.

Table 3.2.3.-II. – *Additional formulae for the construction of the analysis of variance*

$H_P = \frac{n}{d}$	$H_L = \frac{12n}{d^3 - d}$	$K = \frac{n(P_S + P_T + ...)^2}{hd}$

Table 3.2.3.-III. – *Formulae to calculate the sum of squares and degrees of freedom*

Source of variation	Degrees of freedom (*f*)	Sum of squares
Preparations	$h - 1$	$SS_{prep} = H_P(P_S^2 + P_T^2 + ...) - K$
Linear regression	1	$SS_{reg} = \frac{1}{h}H_L(L_S + L_T + ...)2$
Non-parallelism	$h - 1$	$SS_{par} = H_L(L_S^2 + L_T^2 + ...) - SS_{reg}$
Non-linearity*	$h(d-2)$	$SS_{lin} = SS_{treat} - SS_{prep} - SS_{reg} - SS_{par}$
Treatments	$hd - 1$	$SS_{treat} = n(S_1^2 + ... + S_d^2 + T_1^2 + ... + T_d^2 + ...) - K$
* Not calculated for 2-dose assays		

Table 3.2.3.-IV. – *Estimation of the residual error*

Source of variation		Degrees of freedom	Sum of squares
Blocks (rows)*		$n - 1$	$SS_{block} = hd(R_1^2 + ... + R_n^2) - K$
Columns**		$n - 1$	$SS_{col} = hd(C_1^2 + ... + C_n^2) - K$
Residual error***	Completely randomised	$hd(n-1)$	$SS_{res} = SS_{tot} - SS_{treat}$
	Randomised block	$(hd-1)(n-1)$	$SS_{res} = SS_{tot} - SS_{treat} - SS_{block}$
	Latin square	$(hd-2)(n-1)$	$SS_{res} = SS_{tot} - SS_{treat} - SS_{block} - SS_{col}$
Total		$nhd + n - 1$	$SS_{tot} = \sum(y - \bar{y})^2$

For Latin square designs, these formulae are only applicable if $n = hd$
* Not calculated for completely randomised designs
** Only calculated for Latin square designs
*** Depends on the type of design

The calculated potency is an estimate of the "true potency" of each unknown. Confidence limits may be calculated as the antilogarithms of:

$$CM'_T \pm \sqrt{(C-1)(CM'^2_T + 2V)} \qquad (3.2.5.-3)$$

where $C = \frac{SS_{reg}}{SS_{reg} - s^2t^2}$ and $V = \frac{SS_{reg}}{b^2dn}$

The value of t may be obtained from Table 8.2 for $p = 0.05$ and degrees of freedom equal to the number of the degrees

of freedom of the residual error. The estimated potency (R_T) and associated confidence limits are obtained by multiplying the values obtained by A_T after antilogarithms have been taken. If the stock solutions are not exactly equipotent on the basis of assigned and assumed potencies, a correction factor is necessary (See Examples 5.1.2 and 5.1.3).

3.2.6. MISSING VALUES

In a balanced assay, an accident totally unconnected with the applied treatments may lead to the loss of one or more responses, for example because an animal dies. If it is considered that the accident is in no way connected with the composition of the preparation administered, the exact calculations can still be performed but the formulae are necessarily more complicated and can only be given within the framework of general linear models (see Section 7.1). However, there exists an approximate method which keeps the simplicity of the balanced design by replacing the missing response by a calculated value. The loss of information is taken into account by diminishing the degrees of freedom for the total sum of squares and for the residual error by the number of missing values and using one of the formulae below for the missing values. It should be borne in mind that this is only an approximate method, and that the exact method is to be preferred.

If more than one observation is missing, the same formulae can be used. The procedure is to make a rough guess at all the missing values except one, and to use the proper formula for this one, using all the remaining values including the rough guesses. Fill in the calculated value. Continue by similarly calculating a value for the first rough guess. After calculating all the missing values in this way the whole cycle is repeated from the beginning, each calculation using the most recent guessed or calculated value for every response to which the formula is being applied. This continues until 2 consecutive cycles give the same values; convergence is usually rapid.

Provided that the number of values replaced is small relative to the total number of observations in the full experiment (say less than 5 per cent), the approximation implied in this replacement and reduction of degrees of freedom by the number of missing values so replaced is usually fairly satisfactory. The analysis should be interpreted with great care however, especially if there is a preponderance of missing values in one treatment or block, and a biometrician should be consulted if any unusual features are encountered. Replacing missing values in a test without replication is a particularly delicate operation.

Completely randomised design

In a completely randomised assay the missing value can be replaced by the arithmetic mean of the other responses to the same treatment.

Randomised block design

The missing value is obtained using the equation:

$$y' = \frac{nB' + kT' - G'}{(n-1)(k-1)} \qquad (3.2.6.\text{-}1)$$

where B' is the sum of the responses in the block containing the missing value, T' the corresponding treatment total and G' is the sum of all responses recorded in the assay.

Latin square design

The missing value y' is obtained from:

$$y' = \frac{k(B' + C' + T') - 2G'}{(k-1)(k-2)} \qquad (3.2.6.\text{-}2)$$

where B' and C' are the sums of the responses in the row and column containing the missing value. In this case $k = n$.

Cross-over design

If an accident leading to loss of values occurs in a cross-over design, a book on statistics should be consulted (e.g. D.J. Finney, see Section 10), because the appropriate formulae depend upon the particular treatment combinations.

3.3. THE SLOPE-RATIO MODEL

3.3.1. INTRODUCTION

This model is suitable, for example, for some microbiological assays when the independent variable is the concentration of an essential growth factor below the optimal concentration of the medium. The slope-ratio model is illustrated in Figure 3.3.1.-I.

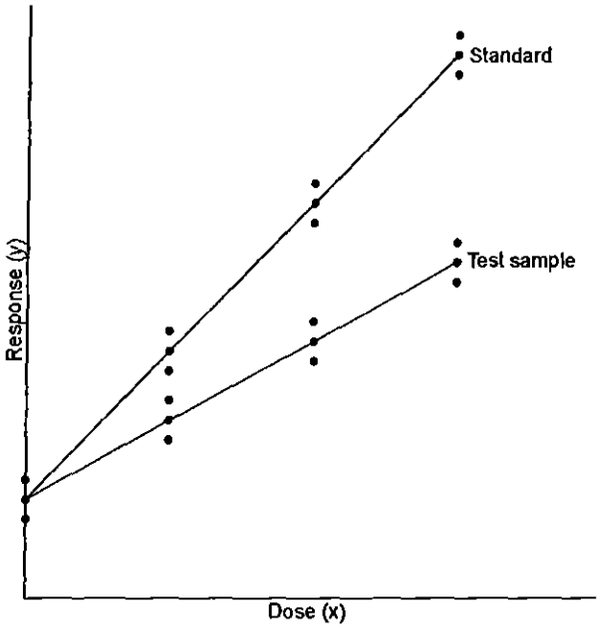

Figure 3.3.1.-I. – *The slope-ratio model for a 2 × 3 + 1 assay*

The doses are represented on the horizontal axis with zero concentration on the left and the highest concentration on the right. The responses are indicated on the vertical axis. The individual responses to each treatment are indicated with black dots. The 2 lines are the calculated dose-response relationship for the standard and the unknown under the assumption that they intersect each other at zero-dose. Unlike the parallel-line model, the doses are not transformed to logarithms.

Just as in the case of an assay based on the parallel-line model, it is important that the assumed potency is close to the true potency, and to prepare equipotent dilutions of the test preparations and the standard (if feasible). The more nearly correct the assumed potency, the closer the 2 lines will be together. The ratio of the slopes represents the "true" potency of the unknown, relative to its assumed potency. If the slope of the unknown preparation is steeper than that of the standard, the potency was underestimated and the calculations will indicate an estimated potency higher than the assumed potency. Similarly, if the slope of the unknown is less steep than that of the standard, the potency was overestimated and the calculations will result in an estimated potency lower than the assumed potency.

In setting up an experiment, all responses should be examined for the fulfilment of the conditions 1, 2 and 3 in

Section 3.1. The analysis of variance to be performed in routine is described in Section 3.3.3 so that compliance with conditions 4B and 5B of Section 3.1 may be examined.

3.3.2. ASSAY DESIGN

The use of the statistical analysis presented below imposes the following restrictions on the assay:

a) the standard and the test preparations must be tested with the same number of equally spaced dilutions,

b) an extra group of experimental units receiving no treatment may be tested (the blanks),

c) there must be an equal number of experimental units to each treatment.

As already remarked in Section 3.1.3, assay designs not meeting these restrictions may be both possible and correct, but the simple statistical analyses presented here are no longer applicable and either expert advice should be sought or suitable software should be used.

A design with 2 doses per preparation and 1 blank, the "common zero ($2h + 1$)-design", is usually preferred, since it gives the highest precision combined with the possibility to check validity within the constraints mentioned above. However, a linear relationship cannot always be assumed to be valid down to zero-dose. With a slight loss of precision a design without blanks may be adopted. In this case 3 doses per preparation, the "common zero ($3h$)-design", are preferred to 2 doses per preparation. The doses are thus given as follows:

1) the standard is given in a high dose, near to but not exceeding the highest dose giving a mean response on the straight portion of the dose-response line,

2) the other doses are uniformly spaced between the highest dose and zero dose,

3) the test preparations are given in corresponding doses based on the assumed potency of the material.

A completely randomised, a randomised block or a Latin square design may be used, such as described in Section 3.2.2. The use of any of these designs necessitates an adjustment to the error sum of squares as described for assays based on the parallel-line model. The analysis of an assay of one or more test preparations against a standard is described below.

3.3.3. ANALYSIS OF VARIANCE

3.3.3.1. The ($hd + 1$)-design

The responses are verified as described in Section 3.1 and, if necessary, transformed. The responses are then averaged over each treatment and each preparation as shown in Table 3.3.3.1.-I. Additionally, the mean response for blanks (B) is calculated.

The sums of squares in the analysis of variance are calculated as shown in Tables 3.3.3.1.-I to 3.3.3.1.-III. The sum of squares due to non-linearity can only be calculated if at least 3 doses of each preparation have been included in the assay. The residual error is obtained by subtracting the variations allowed for in the design from the total variation in response (Table 3.3.3.1.-IV).

The analysis of variance is now completed as follows. Each sum of squares is divided by the corresponding number of degrees of freedom to give mean squares. The mean square for each variable to be tested is now expressed as a ratio to the residual error (s^2) and the significance of these values (known as F-ratios) are assessed by use of Table 8.1 or a suitable sub-routine of a computer program.

3.3.3.2. The (hd)-design

The formulae are basically the same as those for the ($hd + 1$)-design, but there are some slight differences.

— B is discarded from all formulae.

— $K = \frac{n(P_S + P_T + \ldots)^2}{hd}$

— SS_{blank} is removed from the analysis of variance.

— The number of degrees of freedom for treatments becomes $hd - 1$.

— The number of degrees of freedom of the residual error and the total variance is calculated as described for the parallel-line model (see Table 3.2.3.-IV).

Validity of the assay, potency and confidence interval are found as described in Sections 3.3.4 and 3.3.5.

3.3.4. TESTS OF VALIDITY

Assay results are said to be "statistically valid" if the outcome of the analysis of variance is as follows:

1) the variation due to blanks in ($hd + 1$)-designs is not significant, i.e. the calculated probability is not smaller than 0.05. This indicates that the responses of the blanks do not significantly differ from the common intercept and the linear relationship is valid down to zero dose;

2) the variation due to intersection is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 5B, Section 3.1 is satisfied;

3) in assays including at least 3 doses per preparation, the variation due to non-linearity is not significant, i.e. the calculated probability is not less than 0.05. This indicates that condition 4B, Section 3.1 is satisfied.

A significant variation due to blanks indicates that the hypothesis of linearity is not valid near zero dose. If this is likely to be systematic rather than incidental for the type of assay, the (hd-design) is more appropriate. Any response to blanks should then be disregarded.

When these tests indicate that the assay is valid, the potency is calculated with its confidence limits as described in Section 3.3.5.

3.3.5. ESTIMATION OF POTENCY AND CONFIDENCE LIMITS

3.3.5.1. The ($hd + 1$)-design

The common intersection a' of the preparations can be calculated from:

$$a' = \frac{(2d+1)B + (2d-3)ha}{h(2d-3) + 2d + 1} \qquad (3.3.5.1.\text{-}1)$$

The slope of the standard, and similarly for each of the other preparations, is calculated from:

$$b'_S = \frac{6L_S - 3d(d+1)a'}{2d^3 + 3d^2 + d} \qquad (3.3.5.1.\text{-}2)$$

The potency ratio of each of the test preparations can now be calculated from:

$$R'_T = \frac{b'_T}{b'_S} \qquad (3.3.5.1.\text{-}3)$$

which has to be multiplied by A_T, the assumed potency of the test preparation, in order to find the estimated potency R_T. If the step between adjacent doses was not identical for the standard and the test preparation, the potency has to be multiplied by I_S/I_T. Note that, unlike the parallel-line analysis, no antilogarithms are calculated.

Table 3.3.3.1.-I. – *Formulae for slope-ratio assays with d doses of each preparation and a blank*

	Standard (S)	1st Test sample (T)	2nd Test sample (U, etc.)
Mean response lowest dose	S_1	T_1	U_1
Mean response 2nd dose	S_2	T_2	U_2
...	...	...	...
Mean response highest dose	S_d	T_d	U_d
Total preparation	$P_S = S_1 + S_2 + ... + S_d$	$P_T = T_1 + T_2 + ... + T_d$	$P_U = ...$
Linear product	$L_S = 1S_1 + 2S_2 + ... + dS_d$	$L_T = 1T_1 + 2T_2 + ... + dT_d$	$L_U = ...$
Intercept value	$a_S = (4d+2)P_S - 6L_S$	$a_T = (4d+2)P_T - 6L_T$	$a_U = ...$
Slope value	$b_S = 2L_S - (d+1)P_S$	$b_T = 2L_T - (d+1)P_T$	$b_U = ...$
Treatment value	$G_S = S_1^2 + ... + S_d^2$	$G_T = T_1^2 + ... + T_d^2$	$G_U = ...$
Non-linearity*	$J_S = G_S - \frac{P_S^2}{d} - \frac{3b_S^2}{d^3 - d}$	$J_T = G_T - \frac{P_T^2}{d} - \frac{3b_T^2}{d^3 - d}$	$J_U = ...$
* Not calculated for 2-dose assays			

Table 3.3.3.1.-II. – *Additional formulae for the construction of the analysis of variance*

$H_B = \frac{nhd^2 - nhd}{hd^2 - hd + 4d + 2}$	$H_I = \frac{n}{4d^3 - 2d^2 - 2d}$	$a = \frac{a_S + a_T + ...}{h(d^2 - d)}$	$K = \frac{n(B + P_S + P_T + ...)^2}{hd + 1}$

Table 3.3.3.1.-III. – *Formulae to calculate the sum of squares and degrees of freedom*

Source of variation	Degrees of freedom (f)	Sum of squares
Regression	h	$SS_{reg} = SS_{treat} - SS_{blank} - SS_{int} - SS_{lin}$
Blanks	1	$SS_{blank} = H_B(B - a)^2$
Intersection	$h - 1$	$SS_{int} = H_I\left((a_S^2 + a_T^2 + ...) - h(d^2 - d)^2 a^2\right)$
Non-linearity*	$h(d - 2)$	$SS_{lin} = n(J_S + J_T + ...)$
Treatments	hd	$SS_{treat} = n(B^2 + G_S + G_T + ...) - K$
* Not calculated for 2-dose assays		

Table 3.3.3.1.-IV. – *Estimation of the residual error*

Source of variation		Degrees of freedom	Sum of squares
Blocks (rows)*		$n - 1$	$SS_{block} = hd\left(R_1^2 + ... + R_n^2\right) - K$
Columns**		$n - 1$	$SS_{col} = hd\left(C_1^2 + ... + C_n^2\right) - K$
Residual error***	Completely randomised	$(hd + 1)(n - 1)$	$SS_{res} = SS_{tot} - SS_{treat}$
	Randomised block	$hd(n - 1)$	$SS_{res} = SS_{tot} - SS_{treat} - SS_{block}$
	Latin square	$(hd - 1)(n - 1)$	$SS_{res} = SS_{tot} - SS_{treat} - SS_{block} - SS_{col}$
Total		$nhd + n - 1$	$SS_{tot} = \sum(y - \bar{y})^2$

For Latin square designs, these formulae are only applicable if $n = hd$
* Not calculated for completely randomised designs
** Only calculated for Latin square designs
*** Depends on the type of design

The confidence interval for R_T' is calculated from:

$$CR_T' - K' \pm \sqrt{(C-1)(CR_T'2+1) + K'(K' - 2CR_T')} \qquad (3.3.5.1.-4)$$

where $C = \frac{b_S'2}{b_S'2 - s^2 t^2 V_1}$ and $K' = (C-1)V_2$

V_1 and V_2 are related to the variance and covariance of the numerator and denominator of R_T. They can be obtained from:

$$V_1 = \frac{6}{n(2d+1)}\left(\frac{1}{d(d+1)} + \frac{3}{2(2d+1)+hd(d-1)}\right) \qquad (3.3.5.1.-5)$$

$$V_2 = \frac{3d(d+1)}{(3d+1)(d+2)+hd(d-1)} \qquad (3.3.5.1.-6)$$

The confidence limits are multiplied by A_T, and if necessary by I_S/I_T.

3.3.5.2. The (*hd*)-design

The formulae are the same as for the $(hd + 1)$-design, with the following modifications:

$$d' = a \qquad (3.3.5.2.-1)$$

$$V_1 = \frac{6}{nd(2d+1)}\left(\frac{1}{d+1} + \frac{3}{h(d-1)}\right) \qquad (3.3.5.2.-2)$$

$$V_2 = \frac{3(d+1)}{3(d+1)+h(d-1)} \qquad (3.3.5.2.-3)$$

3.4. EXTENDED SIGMOID DOSE-RESPONSE CURVES

This model is suitable, for example, for some immunoassays when analysis is required of extended sigmoid dose-response curves. This model is illustrated in Figure 3.4.-I.

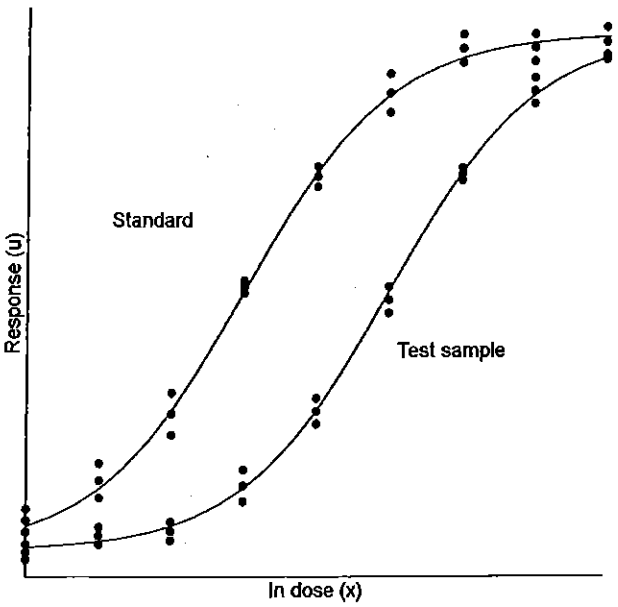

Figure 3.4.-I. – *The four-parameter logistic curve model*

The logarithms of the doses are represented on the horizontal axis with the lowest concentration on the left and the highest concentration on the right. The responses are indicated on the vertical axis. The individual responses to each treatment are indicated with black dots. The 2 curves are the calculated ln(dose)-response relationship for the standard and the test preparation.

The general shape of the curves can usually be described by a logistic function but other shapes are also possible. Each curve can be characterised by 4 parameters: The upper asymptote (α), the lower asymptote (δ), the slope-factor (β), and the horizontal location (γ). This model is therefore often referred to as a four-parameter model. A mathematical representation of the ln(dose)-response curve is:

$$u = \delta + \frac{\alpha - \delta}{1 + e^{-\beta(x-\gamma)}}$$

For a valid assay it is necessary that the curves of the standard and the test preparations have the same slope-factor, and the same maximum and minimum response level at the extreme parts. Only the horizontal location (γ) of the curves may be different. The horizontal distance between the curves is related to the "true" potency of the unknown. If the assay is used routinely, it may be sufficient to test the condition of equal upper and lower response levels when the assay is developed, and then to retest this condition directly only at suitable intervals or when there are changes in materials or assay conditions.

The maximum-likelihood estimates of the parameters and their confidence intervals can be obtained with suitable computer programs. These computer programs may include some statistical tests reflecting validity. For example, if the maximum likelihood estimation shows significant deviations from the fitted model under the assumed conditions of equal upper and lower asymptotes and slopes, then one or all of these conditions may not be satisfied.

The logistic model raises a number of statistical problems which may require different solutions for different types of assays, and no simple summary is possible. A wide variety of possible approaches is described in the relevant literature. Professional advice is therefore recommended for this type of analysis. A simple example is nevertheless included in Section 5.4 to illustrate a "possible" way to analyse the data presented. A short discussion of alternative approaches and other statistical considerations is given in Section 7.5.

If professional advice or suitable software is not available, alternative approaches are possible: 1) if "reasonable" estimates of the upper limit (α) and lower limit (δ) are available, select for all preparations the doses with mean of the responses (u) falling between approximately 20 per cent and 80 per cent of the limits, transform responses of the selected doses to:

$$y = \ln\left(\frac{u-\delta}{\alpha-u}\right)$$

and use the parallel line model (Section 3.2) for the analysis; 2) select a range of doses for which the responses (u) or suitably transformed responses, for example ln u, are approximately linear when plotted against ln(dose); the parallel line model (Section 3.2) may then be used for analysis.

4. ASSAYS DEPENDING UPON QUANTAL RESPONSES

4.1. INTRODUCTION

In certain assays it is impossible or excessively laborious to measure the effect on each experimental unit on a quantitative scale. Instead, an effect such as death or

hypoglycaemic symptoms may be observed as either occurring or not occurring in each unit, and the result depends on the number of units in which it occurs. Such assays are called quantal or all-or-none.

The situation is very similar to that described for quantitative assays in Section 3.1, but in place of n separate responses to each treatment a single value is recorded, i.e. the fraction of units in each treatment group showing a response. When these fractions are plotted against the logarithms of the doses the resulting curve will tend to be sigmoid (S-shaped) rather than linear. A mathematical function that represents this sigmoid curvature is used to estimate the dose-response curve. The most commonly used function is the cumulative normal distribution function. This function has some theoretical merit, and is perhaps the best choice if the response is a reflection of the tolerance of the units. If the response is more likely to depend upon a process of growth, the logistic distribution model is preferred, although the difference in outcome between the 2 models is usually very small.

The maximum likelihood estimators of the slope and location of the curves can be found only by applying an iterative procedure. There are many procedures which lead to the same outcome, but they differ in efficiency due to the speed of convergence. One of the most rapid methods is direct optimisation of the maximum-likelihood function (see Section 7.1), which can easily be performed with computer programs having a built-in procedure for this purpose. Unfortunately, most of these procedures do not yield an estimate of the confidence interval, and the technique to obtain it is too complicated to describe here. The technique described below is not the most rapid, but has been chosen for its simplicity compared to the alternatives. It can be used for assays in which one or more test preparations are compared to a standard. Furthermore, the following conditions must be fulfilled:

1) the relationship between the logarithm of the dose and the response can be represented by a cumulative normal distribution curve,

2) the curves for the standard and the test preparation are parallel, i.e. they are identically shaped and may only differ in their horizontal location,

3) in theory, there is no natural response to extremely low doses and no natural non-response to extremely high doses.

4.2. THE PROBIT METHOD

The sigmoid curve can be made linear by replacing each response, i.e. the fraction of positive responses per group, by the corresponding value of the cumulative standard normal distribution. This value, often referred to as "normit", ranges theoretically from $-\infty$ to $+\infty$. In the past it was proposed to add 5 to each normit to obtain "probits". This facilitated the hand-performed calculations because negative values were avoided. With the arrival of computers the need to add 5 to the normits has disappeared. The term "normit method" would therefore be better for the method described below. However, since the term "probit analysis" is so widely spread, the term will, for historical reasons, be maintained in this text.

Once the responses have been linearised, it should be possible to apply the parallel-line analysis as described in Section 3.2. Unfortunately, the validity condition of homogeneity of variance for each dose is not fulfilled. The variance is minimal at normit = 0 and increases for positive and negative values of the normit. It is therefore necessary to give more weight to responses in the middle part of the curve, and less weight to the more extreme parts of the curve. This method, the analysis of variance, and the estimation of the potency and confidence interval are described below.

4.2.1. TABULATION OF THE RESULTS

Table 4.2.1.-I is used to enter the data into the columns indicated by numbers:

(1) the dose of the standard or the test preparation,

(2) the number n of units submitted to that treatment,

(3) the number of units r giving a positive response to the treatment,

(4) the logarithm x of the dose,

(5) the fraction $p = r/n$ of positive responses per group.

The first cycle starts here.

(6) column Y is filled with zeros at the first iteration,

(7) the corresponding value $\Phi = \Phi(Y)$ of the cumulative standard normal distribution function (see also Table 8.4).

The columns (8) to (10) are calculated with the following formulae:

(8) $$Z = \frac{e^{-Y^2/2}}{\sqrt{2\pi}} \qquad (4.2.1.-1)$$

(9) $$y = Y + \frac{p - \Phi}{Z} \qquad (4.2.1.-2)$$

(10) $$w = \frac{nZ^2}{\Phi - \Phi^2} \qquad (4.2.1.-3)$$

The columns (11) to (15) can easily be calculated from columns (4), (9) and (10) as wx, wy, wx^2, wy^2 and wxy respectively, and the sum (Σ) of each of the columns (10) to (15) is calculated separately for each of the preparations.

The sums calculated in Table 4.2.1.-I are transferred to columns (1) to (6) of Table 4.2.1.-II and 6 additional columns (7) to (12) are calculated as follows:

(7) $$S_{xx} = \sum wx^2 - \frac{(\sum wx)^2}{\sum w} \qquad (4.2.1.-4)$$

(8) $$S_{xy} = \sum wxy - \frac{(\sum wx)(\sum wy)}{\sum w} \qquad (4.2.1.-5)$$

(9) $$S_{yy} = \sum wy^2 - \frac{(\sum wy)^2}{\sum w} \qquad (4.2.1.-6)$$

(10) $$\bar{x} = \frac{\sum wx}{\sum w} \qquad (4.2.1.-7)$$

(11) $$\bar{y} = \frac{\sum wy}{\sum w} \qquad (4.2.1.-8)$$

The common slope b can now be obtained as:

$$b = \frac{\sum S_{xy}}{\sum S_{xx}} \qquad (4.2.1.-9)$$

and the intercept a of the standard, and similarly for the test preparations is obtained as:

(12) $$a = \bar{y} - b\bar{x} \qquad (4.2.1.-10)$$

Column (6) of the first working table can now be replaced by $Y = a + bx$ and the cycle is repeated until the difference between 2 cycles has become small (e.g. the maximum

difference of Y between 2 consecutive cycles is smaller than 10^{-8}).

4.2.2. TESTS OF VALIDITY

Before calculating the potencies and confidence intervals, validity of the assay must be assessed. If at least 3 doses for each preparation have been included, the deviations from linearity can be measured as follows: add a 13th column to Table 4.2.1.-II and fill it with:

$$S_{yy} - \frac{S_{xy}^2}{S_{xx}} \qquad (4.2.2.\text{-}1)$$

The column total is a measure of deviations from linearity and is approximately χ^2 distributed with degrees of freedom equal to $N - 2h$. Significance of this value may be assessed with the aid of Table 8.3 or a suitable sub-routine in a computer program. If the value is significant at the 0.05 probability level, the assay must probably be rejected (see Section 4.2.4).

When the above test gives no indication of significant deviations from linear regression, the deviations from parallelism are tested at the 0.05 significance level with:

$$\chi^2 = \sum \frac{S_{xy}^2}{S_{xx}} - \frac{(\sum S_{xy})^2}{\sum S_{xx}} \qquad (4.2.2.\text{-}2)$$

with $h - 1$ degrees of freedom.

4.2.3. ESTIMATION OF POTENCY AND CONFIDENCE LIMITS

When there are no indications for a significant departure from parallelism and linearity the ln(potency ratio) M'_T is calculated as:

$$M'_T = \frac{a_T - a_S}{b} \qquad (4.2.3.\text{-}1)$$

and the antilogarithm is taken. Now let $t = 1.96$ and $s = 1$. Confidence limits are calculated as the antilogarithms of:

$$CM'_T - (C-1)(\bar{x}_S - \bar{x}_T) \pm \sqrt{(C-1)\left(V \sum S_{xx} + C(M'_T - \bar{x}_S + \bar{x}_T)^2\right)} \qquad (4.2.3.\text{-}2)$$

where $C = \frac{b^2 \sum S_{xx}}{b^2 \sum S_{xx} - s^2 t^2}$ and $V = \frac{1}{\sum_S w} + \frac{1}{\sum_T w}$

4.2.4. INVALID ASSAYS

If the test for deviations from linearity described in Section 4.2.2 is significant, the assay should normally be rejected. If there are reasons to retain the assay, the formulae are slightly modified. t becomes the t-value ($p = 0.05$) with the same number of degrees of freedom as used in the check for linearity and s^2 becomes the χ^2 value divided by the same number of degrees of freedom (and thus typically is greater than 1).

The test for parallelism is also slightly modified. The χ^2 value for non-parallelism is divided by its number of degrees of freedom. The resulting value is divided by s^2 calculated above to obtain an F-ratio with h - 1 and N - $2h$ degrees of freedom, which is evaluated in the usual way at the 0.05 significance level.

4.3. THE LOGIT METHOD

As indicated in Section 4.1 the logit method may sometimes be more appropriate. The name of the method is derived from the logit function which is the inverse of the logistic distribution. The procedure is similar to that described for the probit method with the following modifications in the formulae for Φ and Z.

$$\Phi = \frac{1}{1+e^{-Y}} \qquad (4.3.-1)$$

$$Z = \frac{e^{-Y}}{(1+e^{-Y})^2} \qquad (4.3.-2)$$

4.4. OTHER SHAPES OF THE CURVE

The probit and logit method are almost always adequate for the analysis of quantal responses called for in the European Pharmacopoeia. However, if it can be made evident that the ln(dose)-response curve has another shape than the 2 curves described above, another curve Φ may be adopted. Z is then taken to be the first derivative of Φ.

For example, if it can be shown that the curve is not symmetric, the Gompertz distribution may be appropriate (the gompit method) in which case $\Phi = 1 - e^{-e^{Y}}$ and $Z = e^{Y-e^{Y}}$.

4.5. THE MEDIAN EFFECTIVE DOSE

In some types of assay it is desirable to determine a median effective dose which is the dose that produces a response in 50 per cent of the units. The probit method can be used to determine this median effective dose (ED_{50}), but since there is no need to express this dose relative to a standard, the formulae are slightly different.

Note A standard can optionally be included in order to validate the assay. Usually the assay is considered valid if the calculated ED_{50} of the standard is close enough to the assigned ED_{50}. What "close enough" in this context means depends on the requirements specified in the monograph.

The tabulation of the responses to the test samples, and optionally a standard, is as described in Section 4.2.1. The test for linearity is as described in Section 4.2.2. A test for parallelism is not necessary for this type of assay. The ED_{50} of test sample T, and similarly for the other samples, is obtained as described in Section 4.2.3, with the following modifications in formulae 4.2.3.-1 and 4.2.3.-2:

$$M'_T = \frac{-a_T}{b} \qquad (4.5.-1)$$

$$GM'_T - (C-1)(\bar{x}_T) \pm \sqrt{(C-1)\left(V\sum S_{xx} + C(M'_T - \bar{x}_T)^2\right)} \qquad (4.5.-2)$$

where $V = \frac{1}{\sum_T w}$ and C is left unchanged

5. EXAMPLES

This section consists of worked examples illustrating the application of the formulae. The examples have been selected primarily to illustrate the statistical method of calculation. They are not intended to reflect the most suitable method of assay, if alternatives are permitted in the individual monographs. To increase their value as program checks, more decimal places are given than would usually be necessary. It should also be noted that other, but equivalent methods of calculation exist. These methods should lead to exactly the same final results as those given in the examples.

5.1. PARALLEL-LINE MODEL

5.1.1. TWO-DOSE MULTIPLE ASSAY WITH COMPLETELY RANDOMISED DESIGN

An assay of corticotrophin by subcutaneous injection in rats

The standard preparation is administered at 0.25 and 1.0 units per 100 g of body mass. Two preparations to be examined are both assumed to have a potency of 1 unit per milligram and they are administered in the same quantities as the standard. The individual responses and means per treatment are given in Table 5.1.1.-I. A graphical presentation (Figure 5.1.1.-I) gives no rise to doubt the homogeneity of variance and normality of the data, but suggests problems with parallelism for preparation *U*.

Table 5.1.1.-I. *Response metameter y: mass of ascorbic acid (mg) per 100 g of adrenal gland*

	Standard S		Preparation T		Preparation U	
	S_1	S_2	T_1	T_2	U_1	U_2
	300	289	310	230	250	236
	310	221	290	210	268	213
	330	267	360	280	273	283
	290	236	341	261	240	269
	364	250	321	241	307	251
	328	231	370	290	270	294
	390	229	303	223	317	223
	360	269	334	254	312	250
	342	233	295	216	320	216
	306	259	315	235	265	265
Mean	332.0	248.4	323.9	244.0	282.2	250.0

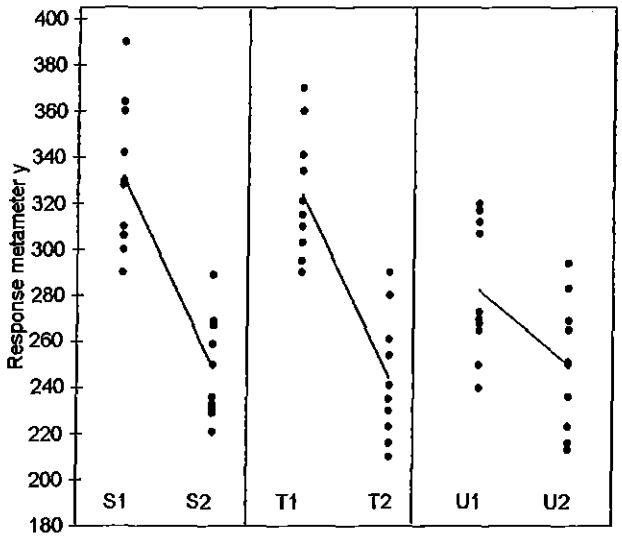

Figure 5.1.1.-I.

The formulae in Tables 3.2.3.-I and 3.2.3.-II lead to:

P_S	=	580.4	L_S	=	−41.8
P_T	=	567.9	L_T	=	−39.95
P_U	=	532.2	L_U	=	−16.1
H_P	=	$\frac{10}{2} = 5$	H_L	=	$\frac{120}{6} = 20$

The analysis of variance can now be completed with the formulae in Tables 3.2.3-III and 3.2.3.-IV. This is shown in Table 5.1.1.-II.

Table 5.1.1.-II. *Analysis of variance*

Source of variation	Degrees of freedom	Sum of squares	Mean square	*F*-ratio	Probability
Preparations	2	6256.6	3128.3		
Regression	1	63 830.8	63 830.8	83.38	0.000
Non-parallelism	2	8218.2	4109.1	5.37	0.007
Treatments	5	78 305.7			
Residual error	54	41 340.9	765.57		
Total	59	119 646.6			

The analysis confirms a highly significant linear regression. Departure from parallelism, however, is also significant ($p = 0.0075$) which was to be expected from the graphical observation that preparation *U* is not parallel to the standard. This preparation is therefore rejected and the analysis repeated using only preparation *T* and the standard (Table 5.1.1.-III).

Table 5.1.1.-III. *Analysis of variance without sample U*

Source of variation	Degrees of freedom	Sum of squares	Mean square	*F*-ratio	Probability
Preparations	1	390.6	390.6		
Regression	1	66 830.6	66 830.6	90.5	0.000
Non-parallelism	1	34.2	34.2	0.05	0.831
Treatments	3	67 255.5			
Residual error	36	26 587.3	738.54		
Total	39	93 842.8			

The analysis without preparation *U* results in compliance with the requirements with respect to both regression and parallelism and so the potency can be calculated.
The formulae in Section 3.2.5 give:
— for the common slope:

$$b = \frac{20(-41.8 - 39.95)}{\ln 4 \times 10 \times 2} = -58.970$$

— the ln(potency ratio) is:

$$M'_T = \frac{567.9 - 580.4}{2 \times (-58.970)} = 0.1060$$

$$C = \frac{66\,830.6}{66\,830.6 - 738.54 \times 2.028^2} = 1.0476$$

$$V = \frac{66\,830.6}{(-58.970)^2 \times 2 \times 10} = 0.9609$$

— and ln(confidence limits) are:

$$1.0476 \times 0.1060 \pm \sqrt{0.0476 \times (1.0476 \times 0.1060^2 + 2 \times 0.9609)} = 0.1110 \pm 0.3034$$

By taking the antilogarithms we find a potency ratio of 1.11 with 95 per cent confidence limits from 0.82-1.51.

Multiplying by the assumed potency of preparation *T* yields a potency of 1.11 units/mg with 95 per cent confidence limits from 0.82 to 1.51 units/mg.

5.1.2. THREE-DOSE LATIN SQUARE DESIGN

Antibiotic agar diffusion assay using a rectangular tray

The standard has an assigned potency of 4855 IU/mg. The test preparation has an assumed potency of 5600 IU/mg. For the stock solutions 25.2 mg of the standard is dissolved in 24.5 mL of solvent and 21.4 mg of the test preparation is dissolved in 23.95 mL of solvent. The final solutions are prepared by first diluting both stock solutions to 1/20 and further using a dilution ratio of 1.5.

A Latin square is generated with the method described in Section 8.6 (see Table 5.1.2.-I). The responses of this routine assay are shown in Table 5.1.2.-II (inhibition zones in mm × 10). The treatment mean values are shown in Table 5.1.2.-III. A graphical representation of the data (see Figure 5.1.2.-I) gives no rise to doubt the normality or homogeneity of variance of the data.

The formulae in Tables 3.2.3.-I and 3.2.3.-II lead to:

$$P_S = 529.667 \qquad L_S = 35.833$$
$$P_T = 526.333 \qquad L_T = 39.333$$
$$H_P = \frac{6}{3} = 2 \qquad H_L = \frac{72}{24} = 3$$

The analysis of variance can now be completed with the formulae in Tables 3.2.3.-III and 3.2.3.-IV. The result is shown in Table 5.1.2.-IV.

The analysis shows significant differences between the rows. This indicates the increased precision achieved by using a Latin square design rather than a completely randomised design. A highly significant regression and no significant departure of the individual regression lines from parallelism and linearity confirms that the assay is satisfactory for potency calculations.

Table 5.1.2.-I. *Distribution of treatments over the plate*

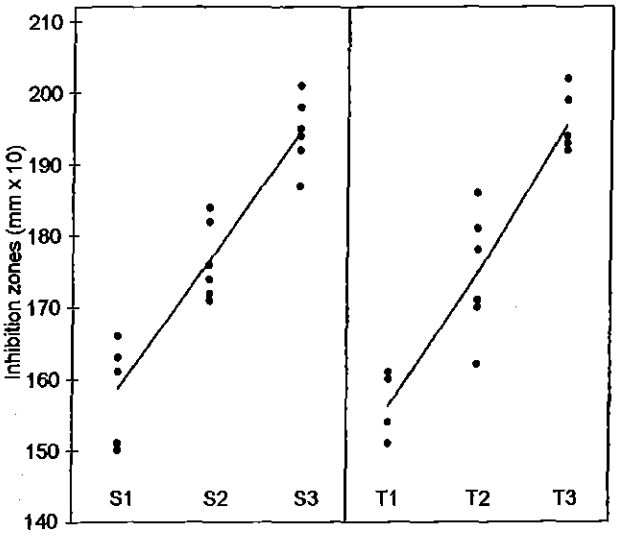

Figure 5.1.2.-I.

Table 5.1.2.-IV. *Analysis of variance*

Source of variation	Degrees of freedom	Sum of squares	Mean square	*F*-ratio	Probability
Preparations	1	11.1111	11.1111		
Regression	1	8475.0417	8475.0417	408.1	0.000
Non-parallelism	1	18.3750	18.3750	0.885	0.358
Non-linearity	2	5.4722	2.7361	0.132	0.877
Treatments	5	8510			
Rows	5	412	82.40	3.968	0.012
Columns	5	218.6667	43.73	2.106	0.107
Residual error	20	415.3333	20.7667		
Total	35	9556			

The formulae in Section 3.2.5 give:

— for the common slope:

$$b = \frac{3 \times (35.833 + 39.333)}{\ln(1.5) \times 6 \times 2} = 46.346$$

— the ln(potency ratio) is:

$$M'_T = \frac{526.333 - 529.667}{3 \times 46.346} = -0.023974$$

$$C = \frac{8475.0417}{8475.0417 - 20.7667 \times 2.086^2} = 1.0108$$

$$V = \frac{8475.0417}{46.346^2 \times 3 \times 6} = 0.2192$$

— and ln(confidence limits) are:

$$1.0108 \times (-0.0240) \pm \sqrt{0.0108 \times (1.0108 \times (-0.0240)^2 + 2 \times 0.2192)}$$

$$= -0.02423 \pm 0.06878$$

The potency ratio is found by taking the antilogarithms, resulting in 0.9763 with 95 per cent confidence limits from 0.9112-1.0456.

A correction factor of:

$$\frac{4855 \times 25.2/24.5}{5600 \times 21.4/23.95} = 0.99799$$

is necessary because the dilutions were not exactly equipotent on the basis of the assumed potency. Multiplying by this correction factor and the assumed potency of 5600 IU/mg yields a potency of 5456 IU/mg with 95 per cent confidence limits from 5092 to 5843 IU/mg.

5.1.3. FOUR-DOSE RANDOMISED BLOCK DESIGN

Antibiotic turbidimetric assay

This assay is designed to assign a potency in international units per vial. The standard has an assigned potency of 670 IU/mg. The test preparation has an assumed potency of 20 000 IU/vial. On the basis of this information the stock solutions are prepared as follows. 16.7 mg of the standard is dissolved in 25 mL solvent and the contents of one vial of the test preparation are dissolved in 40 mL solvent. The final solutions are prepared by first diluting to 1/40 and further using a dilution ratio of 1.5. The tubes are placed in a water-bath in a randomised block arrangement (see Section 8.5). The responses are listed in Table 5.1.3.-I.

Inspection of Figure 5.1.3.-I gives no rise to doubt the validity of the assumptions of normality and homogeneity of variance of the data. The standard deviation of S_3 is somewhat high but is no reason for concern.

Table 5.1.3.-I. *Absorbances of the suspensions (× 1000)*

	Standard *S*				Preparation *T*				
Block	S_1	S_2	S_3	S_4	T_1	T_2	T_3	T_4	Mean
1	252	207	168	113	242	206	146	115	181.1
2	249	201	187	107	236	197	153	102	179.0
3	247	193	162	111	246	197	148	104	176.0
4	250	207	155	108	231	191	159	106	175.9
5	235	207	140	98	232	186	146	95	167.4
Mean	246.6	203.0	162.4	107.4	237.4	195.4	150.4	104.4	

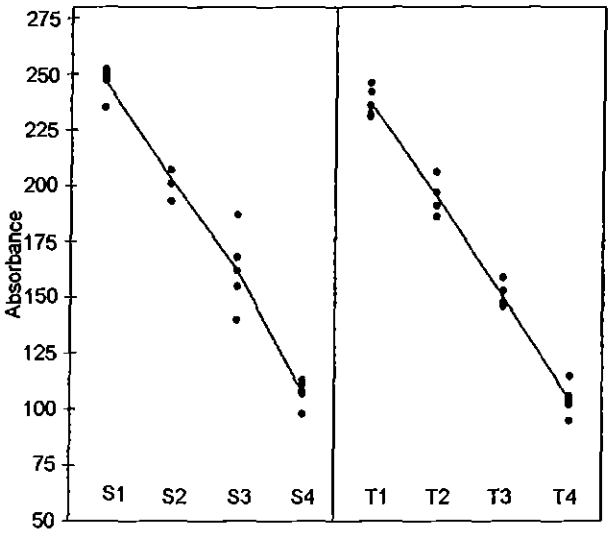

Figure 5.1.3.-I.

The formulae in Tables 3.2.3.-I and 3.2.3.-II lead to:

$P_S = 719.4$ $L_S = -229.1$
$P_T = 687.6$ $L_T = -222$
$H_P = \frac{5}{4} = 1.25$ $H_L = \frac{60}{60} = 1$

The analysis of variance is constructed with the formulae in Tables 3.2.3.-III and 3.2.3.-IV. The result is shown in Table 5.1.3.-II.

Table 5.1.3.-II. *Analysis of variance*

Source of variation	Degrees of freedom	Sum of squares	Mean square	*F*-ratio	Probability
Preparations	1	632.025	632.025		
Regression	1	101 745.6	101 745.6	1887.1	0.000
Non-parallelism	1	25.205	25.205	0.467	0.500
Non-linearity	4	259.14	64.785	1.202	0.332
Treatments	7	102 662			
Blocks	4	876.75	219.188	4.065	0.010
Residual error	28	1509.65	53.916		
Total	39	105 048.4			

A significant difference is found between the blocks. This indicates the increased precision achieved by using a randomised block design. A highly significant regression and no significant departure from parallelism and linearity confirms that the assay is satisfactory for potency calculations. The formulae in Section 3.2.5 give:
— for the common slope:

$$b = \frac{1 \times (-229.1 - 222)}{\ln(1.5) \times 5 \times 2} = 111.255$$

— the ln(potency ratio) is:

$$M'_T = \frac{687.6 - 719.4}{4 \times (-111.255)} = 0.071457$$

$$C = \frac{101\ 745.6}{101\ 745.6 - 53.916 \times 2.048^2} = 1.00223$$

$$V = \frac{101\ 745.6}{(-111.255)^2 \times 4 \times 5} = 0.4110$$

— and ln(confidence limits) are:

$$1.00223 \times 0.0715 \pm \sqrt{0.00223 \times (1.00223 \times 0.0715^2 + 2 \times 0.4110)}$$

$$= 0.07162 \pm 0.04293$$

The potency ratio is found by taking the antilogarithms, resulting in 1.0741 with 95 per cent confidence limits from 1.0291 to 1.1214. A correction factor of:

$$\frac{670 \times 16.7/25}{20\ 000 \times 1/40} = 0.89512$$

is necessary because the dilutions were not exactly equipotent on the basis of the assumed potency. Multiplying by this correction factor and the assumed potency of 20 000 IU/vial yields a potency of 19 228 IU/vial with 95 per cent confidence limits from 18 423-20 075 IU/vial.

5.1.4. FIVE-DOSE MULTIPLE ASSAY WITH COMPLETELY RANDOMISED DESIGN

An in-vitro assay of three hepatitis B vaccines against a standard

Three independent two-fold dilution series of 5 dilutions were prepared from each of the vaccines. After some additional steps in the assay procedure, absorbances were measured. They are shown in Table 5.1.4.-I.

Table 5.1.4.-I. *Optical densities*

Dilution	Standard *S*			Preparation *T*		
1:16 000	0.043	0.045	0.051	0.097	0.097	0.094
1:8000	0.093	0.099	0.082	0.167	0.157	0.178
1:4000	0.159	0.154	0.166	0.327	0.355	0.345
1:2000	0.283	0.295	0.362	0.501	0.665	0.576
1:1000	0.514	0.531	0.545	1.140	1.386	1.051

Dilution	Preparation *U*			Preparation *V*		
1:16 000	0.086	0.071	0.073	0.082	0.082	0.086
1:8000	0.127	0.146	0.133	0.145	0.144	0.173
1:4000	0.277	0.268	0.269	0.318	0.306	0.316
1:2000	0.586	0.489	0.546	0.552	0.551	0.624
1:1000	0.957	0.866	1.045	1.037	1.039	1.068

The logarithms of the optical densities are known to have a linear relationship with the logarithms of the doses.
The mean responses of the ln-transformed optical densities are listed in Table 5.1.4.-II. No unusual features are discovered in a graphical presentation of the data (Figure 5.1.4.-I).

Table 5.1.4.-II. *Means of the ln-transformed absorbances*

S_1	−3.075	T_1	−2.344	U_1	−2.572	V_1	−2.485
S_2	−2.396	T_2	−1.789	U_2	−2.002	V_2	−1.874

S_4	−1.166	T_4	−0.550	U_4	−0.618	V_4	−0.554
S_5	−0.635	T_5	0.169	U_5	−0.048	V_5	0.047

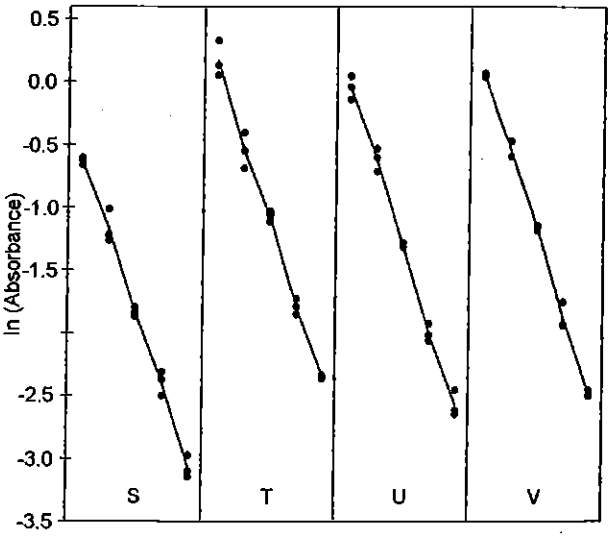

Figure 5.1.4.-I.

The formulae in Tables 3.2.3.-I and 3.2.3.-II give:

$P_S = -9.108$ $L_S = 6.109$
$P_T = -5.586$ $L_T = 6.264$
$P_U = -6.544$ $L_U = 6.431$
$P_V = -6.027$ $L_V = 6.384$
$H_P = \frac{3}{5} = 0.6$ $H_L = \frac{36}{120} = 0.3$

The analysis of variance is completed with the formulae in Tables 3.2.3.-III and 3.2.3.-IV. This is shown in Table 5.1.4.-III.

Table 5.1.4.-III. *Analysis of variance*

Source of variation	Degrees of freedom	Sum of squares	Mean square	*F*-ratio	Probability
Preparations	3	4.475	1.492		
Regression	1	47.58	47.58	7126	0.000
Non-parallelism	3	0.0187	0.006	0.933	0.434
Non-linearity	12	0.0742	0.006	0.926	0.531
Treatments	19	52.152			
Residual error	40	0.267	0.0067		
Total	59	52.42			

A highly significant regression and a non-significant departure from parallelism and linearity confirm that the potencies can be safely calculated. The formulae in Section 3.2.5 give:

— for the common slope:

$$b = \frac{0.3 \times (6.109 + 6.264 + 6.431 + 6.384)}{\ln 2 \times 3 \times 4} = 0.90848$$

— the ln(potency ratio) for preparation T is:

$$M'_T = \frac{-5.586 - (-9.108)}{5 \times 0.90848} = 0.7752$$

$$C = \frac{47.58}{47.58 - 0.0067 \times 2.021^2} = 1.00057$$

$$V = \frac{47.58}{0.9085^2 \times 5 \times 3} = 3.8436$$

— and ln(confidence limits) for preparation T are:

$$1.00057 \times 0.7752 \pm$$

$$\sqrt{0.00057 \times (1.00057 \times 0.7752^2 + 2 \times 3.8436)}$$

$$= 0.7756 \pm 0.0689$$

By taking the antilogarithms a potency ratio of 2.171 is found with 95 per cent confidence limits from 2.027 to 2.327. All samples have an assigned potency of 20 µg protein/mL and so a potency of 43.4 µg protein/mL is found for test preparation T with 95 per cent confidence limits from 40.5-46.5 µg protein/mL.

The same procedure is followed to estimate the potency and confidence interval of the other test preparations. The results are listed in Table 5.1.4.-IV.

Table 5.1.4.-IV. *Final potency estimates and 95 per cent confidence intervals of the test vaccines (in µg protein/mL)*

	Lower limit	Estimate	Upper limit
Vaccine *T*	40.5	43.4	46.5
Vaccine *U*	32.9	35.2	37.6
Vaccine *V*	36.8	39.4	42.2

5.1.5. TWIN CROSS-OVER DESIGN

Assay of insulin by subcutaneous injection in rabbits

The standard preparation was administered at 1 unit and 2 units per millilitre. Equivalent doses of the unknown preparation were used based on an assumed potency of 40 units per millilitre. The rabbits received subcutaneously 0.5 mL of the appropriate solutions according to the design in Table 5.1.5.-I and responses obtained are shown in Table 5.1.5.-II and Figure 5.1.5.-I. The large variance illustrates the variation between rabbits and the need to employ a cross-over design.

Table 5.1.5.-I. *Arrangements of treatments*

	Group of rabbits			
	1	2	3	4
Day 1	S_1	S_2	T_1	T_2
Day 2	T_2	T_1	S_2	S_1

Table 5.1.5.-II. *Response y: sum of blood glucose readings (mg/100 mL) at 1 h and 2.5 h*

	Group 1		Group 2		Group 3		Group 4	
	S_1	T_2	S_2	T_1	T_1	S_2	T_2	S_1
	112	104	65	72	105	91	118	144
	126	112	116	160	83	67	119	149

	116	91	50	65	66	55	39	87
	101	68	55	100	91	68	31	71
Mean	95.6	82.8	69.6	93.3	89.9	66.6	72.4	106.8

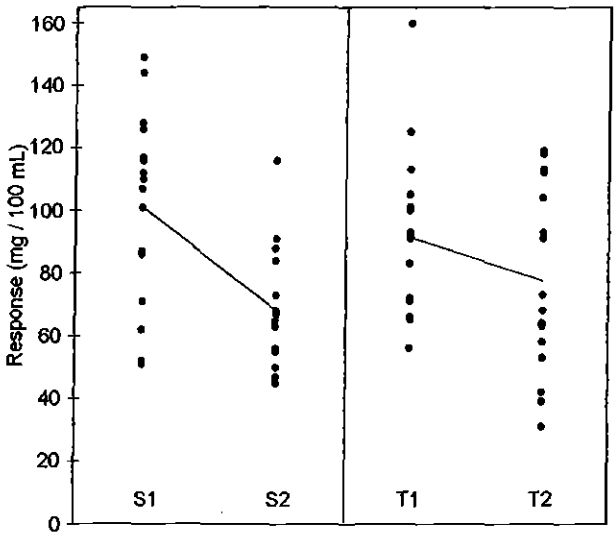

Figure 5.1.5.-I.

The analysis of variance is more complicated for this assay than for the other designs given because the component of the sum of squares due to parallelism is not independent of the component due to rabbit differences. Testing of the

parallelism of the regression lines involves a second error-mean-square term obtained by subtracting the parallelism component and 2 "interaction" components from the component due to rabbit differences.

Three "interaction" components are present in the analysis of variance due to replication within each group:

days × preparation; days × regression; days × parallelism.

These terms indicate the tendency for the components (preparations, regression and parallelism) to vary from day to day. The corresponding F-ratios thus provide checks on these aspects of assay validity. If the values of F obtained are significantly high, care should be exercised in interpreting the results of the assay and, if possible, the assay should be repeated.

The analysis of variance is constructed by applying the formulae given in Tables 3.2.3.-I to 3.2.3.-III separately for both days and for the pooled set of data. The formulae in Tables 3.2.3.-I and 3.2.3.-II give:

Day 1:	P_S	=	165.25	L_S	=	−13
	P_T	=	162.25	L_T	=	−8.75
	H_P	=	$\frac{8}{2}=4$	H_L	=	$\frac{96}{6}=16$
Day 2:	P_S	=	173.38	L_S	=	−20.06
	P_T	=	176.00	L_T	=	−5.25
	H_P	=	$\frac{8}{2}=4$	H_L	=	$\frac{96}{6}=16$
Pooled:	P_S	=	169.31	L_S	=	−16.53
	P_T	=	169.13	L_T	=	−7.00
	H_P	=	$\frac{16}{2}=8$	H_L	=	$\frac{192}{6}=32$

and with the formulae in Table 3.2.3.-III this leads to:

Day 1			Day 2			Pooled		
SS_{prep}	=	18.000	SS_{prep}	=	13.781	SS_{prep}	=	0.141
SS_{reg}	=	3784.5	SS_{reg}	=	5125.8	SS_{reg}	=	8859.5
SS_{par}	=	144.5	SS_{par}	=	1755.3	SS_{par}	=	1453.5

The interaction terms are found as Day 1 + Day 2 - Pooled.

$$SS_{\text{days}\times\text{prep}} = 31.64$$

$$SS_{\text{days}\times\text{reg}} = 50.77$$

$$SS_{\text{days}\times\text{par}} = 446.27$$

In addition the sum of squares due to day-to-day variation is calculated as:

$$SS_{\text{days}} = \frac{1}{2}N(D_1^2+D_2^2) - K = 478.52$$

and the sum of squares due to blocks (the variation between rabbits) as:

$$SS_{\text{block}} = 2\sum B_i^2 - K = 39\,794.7$$

where B_i is the mean response per rabbit.

The analysis of variance can now be completed as shown in Table 5.1.5.-III.

Table 5.1.5.-III. *Analysis of variance*

Source of variation	Degrees of freedom	Sum of squares	Mean square	F-ratio	Probability
Non-parallelism	1	1453.5	1453.5	1.064	0.311
Days × Prep.	1	31.6	31.6	0.023	0.880
Days × Regr.	1	50.8	50.8	0.037	0.849
Residual error between rabbits	28	38 258.8	1366.4		
Rabbits	31	39 794.7	1283.7		
Preparations	1	0.14	0.14	0.001	0.975
Regression	1	8859.5	8859.5	64.532	0.000
Days	1	478.5	478.5	3.485	0.072
Days × non-par.	1	446.3	446.3	3.251	0.082
Residual error within rabbits	28	3844.1	137.3		
Total	63	53 423.2			

The analysis of variance confirms that the data fulfil the necessary conditions for a satisfactory assay: a highly significant regression, no significant departures from parallelism, and none of the three interaction components is significant.

The formulae in Section 3.2.5 give:

— for the common slope:

$$b = \frac{32\times(-16.53-7)}{\ln 2\times 16\times 2} = -33.95$$

— the ln(potency ratio) is:

$$M'_T = \frac{169.13-169.31}{2\times(-33.95)} = 0.00276$$

$$C = \frac{8859.5}{8859.5 - 137.3\times 2.048^2} = 1.0695$$

$$V = \frac{8859.5}{(-33.95)^2\times 2\times 16} = 0.2402$$

— and ln(confidence limits) are:

$$1.0695\times 0.00276 \pm \sqrt{0.0695\times(1.0695\times 0.00276^2 + 2\times 0.2402)} = 0.00295 \pm 0.18279$$

By taking the antilogarithms a potency ratio of 1.003 with 95 per cent confidence limits from 0.835 to 1.204 is found. Multiplying by A_T = 40 yields a potency of 40.1 units per millilitre with 95 per cent confidence limits from 33.4-48.2 units per millilitre.

5.2. SLOPE-RATIO MODEL

5.2.1. A COMPLETELY RANDOMISED (0,3,3)-DESIGN

An assay of factor VIII

A laboratory carries out a chromogenic assay of factor VIII activity in concentrates. The laboratory has no experience with the type of assay but is trying to make it operational. Three equivalent dilutions are prepared of both the standard and the test preparation. In addition a blank is prepared, although a linear dose-response relationship is not expected

for low doses. 8 replicates of each dilution are prepared, which is more than would be done in a routine assay.

A graphical presentation of the data shows clearly that the dose-response relationship is indeed not linear at low doses. The responses to blanks will therefore not be used in the calculations (further assays are of course needed to justify this decision). The formulae in Tables 3.3.3.1.-I and 3.3.3.1.-II yield:

$P_S = 0.6524$ $P_T = 0.5651$
$L_S = 1.4693$ $L_T = 1.2656$
$a_S = 0.318$ $a_T = 0.318$
$b_S = 0.329$ $b_T = 0.271$
$G_S = 0.1554$ $G_T = 0.1156$
$J_S = 4.17 \cdot 10^{-8}$ $J_T = 2.84 \cdot 10^{-6}$

And

$H_I = 0.09524$ $a' = 0.05298$ $K = 1.9764$

and the analysis of variance is completed with the formulae in Tables 3.3.3.1.-III and 3.3.3.1.-IV.

A highly significant regression and no significant deviations from linearity and intersection indicate that the potency can be calculated.

Slope of standard:

$$b'_S = \frac{6 \times 1.469 - 36 \times 0.0530}{84} = 0.0822$$

Slope of test sample:

$$b'_T = \frac{6 \times 1.266 - 36 \times 0.0530}{84} = 0.0677$$

Formula 3.3.5.1.-3 gives:

$$R = \frac{0.0677}{0.0822} = 0.823$$

$$C = \frac{0.0822^2}{0.0822^2 - 3.86 \cdot 10^{-6} \times 2.018^2 \times 0.0357} = 1.000083$$

$$K' = 0.000083 \times 0.75 = 0.000062$$

and the 95 per cent confidence limits are:

$$0.823 \pm \sqrt{0.000083 \times 1.678 + 0.000062 \times (-1.646)} = 0.823 \pm 0.006$$

The potency ratio is thus estimated as 0.823 with 95 per cent confidence limits from 0.817 to 0.829.

Table 5.2.1.-I. *Absorbances*

	Blank	Standard S (in IU/mL)			Preparation T (in IU/mL)		
Conc.	B	S_1 0.01	S_2 0.02	S_3 0.03	T_1 0.01	T_2 0.02	T_3 0.03

Total	47	0.1919			

5.2.2. A COMPLETELY RANDOMISED (0,4,4,4)-DESIGN

An in-vitro assay of influenza vaccines

The haemagglutinin antigen (HA) content of 2 influenza vaccines is determined by single radial immunodiffusion. Both have a labelled potency of 15 µg HA per dose, which is

equivalent with a content of 30 µg HA/mL. The standard has an assigned content of 39 µg HA/mL.

Standard and test vaccines are applied in 4 duplicate concentrations which are prepared on the basis of the assigned and the labelled contents. When the equilibrium between the external and the internal reactant is established, the zone of the annulus precipitation area is measured. The results are shown in Table 5.2.2.-I.

Table 5.2.2.-I. *Zone of precipitation area (mm^2)*

Conc.	Standard *S*		Preparation *T*		Preparation *U*	
(µg/mL)	I	II	I	II	I	II
7.5	18.0	18.0	15.1	16.8	15.4	15.7
15.0	22.8	24.5	23.1	24.2	20.2	18.6
22.5	30.4	30.4	28.9	27.4	24.2	23.1
30.0	35.7	36.6	34.4	37.8	27.4	27.0

A graphical presentation of the data shows no unusual features (see Figure 5.2.2.-I). The formulae in Tables 3.3.3.1.-I and 3.3.3.1.-II yield:

P_S	=	108.2	P_T	=	103.85	P_U	=	85.8
L_S	=	301.1	L_T	=	292.1	L_U	=	234.1
a_S	=	141.0	a_T	=	116.7	a_U	=	139.8
b_S	=	61.2	b_T	=	64.95	b_U	=	39.2
G_S	=	3114.3	G_T	=	2909.4	G_U	=	1917.3
J_S	=	0.223	J_T	=	2.227	J_U	=	0.083

and

H_I	=	0.0093	a'	=	11.04	K	=	14 785.8

and the analysis of variance is completed with the formulae in Tables 3.3.3.1.-III and 3.3.3.1.-IV. This is shown in Table 5.2.2.-II.

A highly significant regression and no significant deviations from linearity and intersection indicate that the potency can be calculated.

Slope of standard:

$$b'_S = \frac{6 \times 301.1 - 60 \times 11.04}{180} = 6.356$$

Slope of *T* is:

$$b'_T = \frac{6 \times 292.1 - 60 \times 11.04}{180} = 6.056$$

Slope of *U* is:

$$b'_U = \frac{6 \times 234.1 - 60 \times 11.04}{180} = 4.123$$

This leads to a potency ratio of 6.056/6.356 = 0.953 for vaccine *T* and 4.123/6.356 = 0.649 for vaccine *U*.

$$C = \frac{6.356^2}{6.356^2 - 1.068 \times 2.179^2 \times 0.0444} = 1.0056$$

$$K' = 0.0056 \times 0.625 = 0.0035$$

And the confidence limits are found with formula 3.3.5.1.-4.

For vaccine *T*:

$$0.955 \pm \sqrt{0.0056 \times 1.913 + 0.0035 \times (-1.913)} = 0.955 \pm 0.063$$

For vaccine *U*:

$$0.649 \pm \sqrt{0.0056 \times 1.423 + 0.0035 \times (-1.301)} = 0.649 \pm 0.058$$

The HA content in µg/dose can be found by multiplying the potency ratios and confidence limits by the assumed content of 15 µg/dose. The results are given in Table 5.2.2.-III.

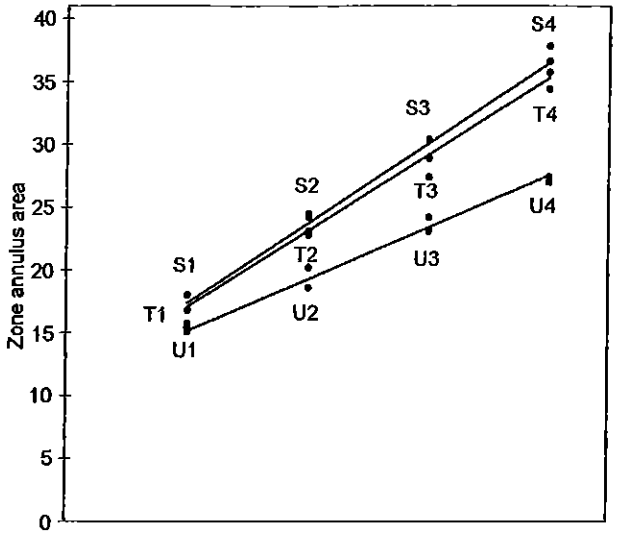

Figure 5.2.2.-I.

Table 5.2.2.-II. *Analysis of variance*

Source of variation	Degrees of freedom	Sum of squares	Mean square	*F*-ratio	Probability

5.3. QUANTAL RESPONSES

5.3.1. PROBIT ANALYSIS OF A TEST PREPARATION AGAINST A REFERENCE

An in-vivo assay of a diphtheria vaccine

A diphtheria vaccine (assumed potency 140 IU/vial) is assayed against a standard (assigned potency 132 IU/vial). On the basis of this information, equivalent doses are prepared and randomly administered to groups of guinea-pigs. After a given period, the animals are challenged with

diphtheria toxin and the number of surviving animals recorded as shown in Table 5.3.1.-I.

Table 5.3.1.-I. *Raw data from a diphtheria assay in guinea-pigs*

Standard (*S*) Assigned potency 132 IU/vial			Test preparation (*T*) Assumed potency 140 IU/vial		
dose (IU/mL)	challenged	protected	dose (I.U./mL)	challenged	protected
1.0	12	0	1.0	11	0
1.6	12	3	1.6	12	4
2.5	12	6	2.5	11	8
4.0	11	10	4.0	11	10

The observations are transferred to the first working table and the subsequent columns are computed as described in Section 4.2.1. Table 5.3.1.-II shows the first cycle of this procedure.

The sums of the last 6 columns are then calculated per preparation and transferred to the second working table (see Table 5.3.1.-III). The results in the other columns are found with formulae 4.2.1.-4 to 4.2.1.-10. This yields a common slope b of 1.655.

The values for Y in the first working table are now replaced by $a + bx$ and a second cycle is carried out (see Table 5.3.1.-IV).

The cycle is repeated until the difference between 2 consecutive cycles has become small. The second working table should then appear as shown in Table 5.3.1.-V.

Linearity is tested as described in Section 4.2.2. The χ^2-value with 4 degrees of freedom is 0.851 + 1.070 = 1.921 representing a p-value of 0.750 which is not significant.

Since there are no significant deviations from linearity, the test for parallelism can be carried out as described in the same section. The χ^2-value with 1 degree of freedom is:

$$(16.71 + 17.27) - \frac{14.15^2}{5.89} = 0.001$$

representing a p-value of 0.974 which is not significant.

The ln(potency ratio) can now be estimated as described in Section 4.2.3.

$$M'_T = \frac{-1.721 - (-2.050)}{2.401} = 0.137$$

Further:

$$C = \frac{2.401^2 \times 5.893}{2.401^2 \times 5.893 - 1^2 \times 1.960^2} = 1.127$$

$$V = \frac{1}{18.37} + \frac{1}{17.96} = 0.110$$

So ln confidence limits are:

$$0.155 - 0.013 \pm \sqrt{0.127(0.649 + 1.127 \times 0.036^2)} = 0.142 \pm 0.288$$

The potency and confidence limits can now be found by taking the antilogarithms and multiplying these by the assumed potency of 140 IU/vial. This yields an estimate of 160.6 IU/vial with 95 per cent confidence limits from 121.0-215.2 IU/vial.

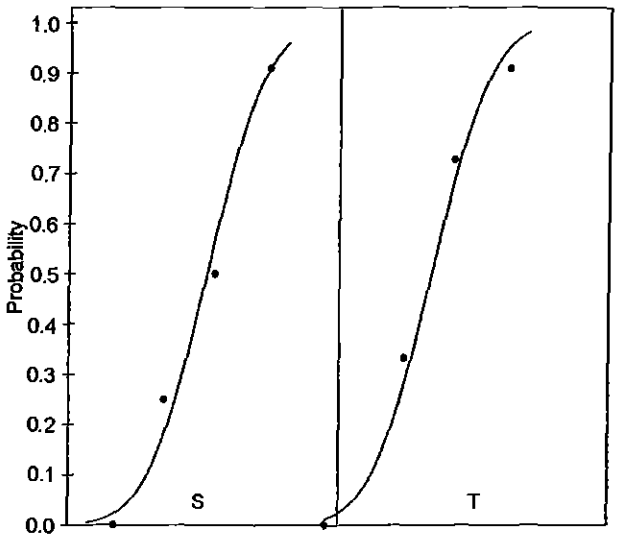

Figure 5.3.1.-I.

5.3.2. LOGIT ANALYSIS AND OTHER TYPES OF ANALYSES OF A TEST PREPARATION AGAINST A REFERENCE

Results will be given for the situation where the logit method and other "classical" methods of this family are applied to the data in Section 5.3.1. This should be regarded as an exercise rather than an alternative to the probit method in this specific case. Another shape of the curve may be adopted only if this is supported by experimental or theoretical evidence. See Table 5.3.2.-I.

Table 5.3.2.-I. *Results by using alternative curves*

	Logit	Gompit	Angle*
Φ	$\frac{1}{1+e^{-Y}}$	$1-e^{-e^{Y}}$	$\frac{1}{2}\sin Y + \frac{1}{2}$
Z	$\frac{e^{-Y}}{(1+e^{-Y})^2}$	$e^{Y-e^{Y}}$	$\frac{1}{2}\cos Y$
slope b	4.101	2.590	1.717
χ^2 lin	2.15	3.56	1.50
χ^2 par	0.0066	0.168	0.0010
Potency	162.9	158.3	155.8
Lower limit	121.1	118.7	122.6
Upper limit	221.1	213.3	200.7

* If $Y - \frac{1}{2}\pi$ then $\Phi = 0$ and $Z = 0$
If $Y \frac{1}{2}\pi$ then $\Phi = 1$ and $Z = 0$

5.3.3. THE ED_{50} DETERMINATION OF A SUBSTANCE USING THE PROBIT METHOD

An in-vitro assay of oral poliomyelitis vaccine

In an ED_{50} assay of oral poliomyelitis vaccine with 10 different dilutions in 8 replicates of 50 µL on an ELISA-plate, results were obtained as shown in Table 5.3.3.-I.

The observations are transferred to the first working table and the subsequent columns are computed as described in Section 4.2.1. Table 5.3.3.-II shows the first cycle of this procedure.

The sums of the last 6 columns are calculated and transferred to the second working table (see Table 5.3.3.-III). The results in the other columns are found with formulae 4.2.1.-4 to 4.2.1.-10. This yields a common slope b of −0.295.

The values for Y in the first working table are now replaced by $a + bx$ and a second cycle is carried out. The cycle is repeated until the difference between 2 consecutive cycles has become small. The second working table should then appear as shown in Table 5.3.3.-IV.

Linearity is tested as described in Section 4.2.2. The χ^2-value with 8 degrees of freedom is 2.711 representing a p-value of 0.951 which is not significant.

The potency ratio can now be estimated as described in Section 4.5.

$$M_T' = \frac{-(-7.931)}{-0.646} = -12.273$$

Further:

Table 5.3.3.-II. *First working table in the first cycle*

	$10^{-8.0}$	8	8	−18.42	1.000	0.00	0.5	0.399	1.253	5.09	−93.82	6.38	1728.2	8.00	−117.6

Table 5.3.3.-III. *Second working table in the first cycle*

Vaccine	Σw	Σwx	Σwy	Σwx^2	Σwy^2	Σwxy	S_{xx}	S_{xy}	S_{yy}	$\bar{x}$	$\bar{y}$	a
T	50.93	−674.3	11.17	9484.6	57.50	−312.32	556.92	−164.43	55.05	−13.24	0.219	−3.690

Table 5.3.3.-IV. *Second working table after sufficient cycles*

Vaccine	Σw	Σwx	Σwy	Σwx^2	Σwy^2	Σwxy	S_{xx}	S_{xy}	S_{yy}	$\bar{x}$	$\bar{y}$	a
T	19.39	−238.2	0.11	2981.1	26.05	−37.45	55.88	−36.11	26.05	−12.28	0.006	−7.931

$$C = \frac{(-0.646)^2 \times 55.883}{(-0.646)^2 \times 55.883 - 1^2 \times 1.960^2} = 1.197$$

$$V = \frac{1}{19.39} = 0.052$$

So ln confidence limits are:

$$-14.692 - (-2.420) \pm \sqrt{0.197 \times (2.882 + 1.197 \times 0.009^2)}$$

$$= -12.272 \pm 0.754$$

This estimate is still expressed in terms of the ln(dilutions). In order to obtain estimates expressed in ln(ED_{50})/mL the values are transformed to:

$$-M'_T + \ln\left(\frac{1000}{50}\right)$$

Since it has become common use to express the potency of this type of vaccine in terms of $\log_{10}(ED_{50})$/mL, the results have to be divided by ln(10). The potency is thus estimated as 6.63 $\log_{10}(ED_{50})$/mL with 95 per cent confidence limits from 6.30 to 6.96 $\log_{10}(ED_{50})$/mL.

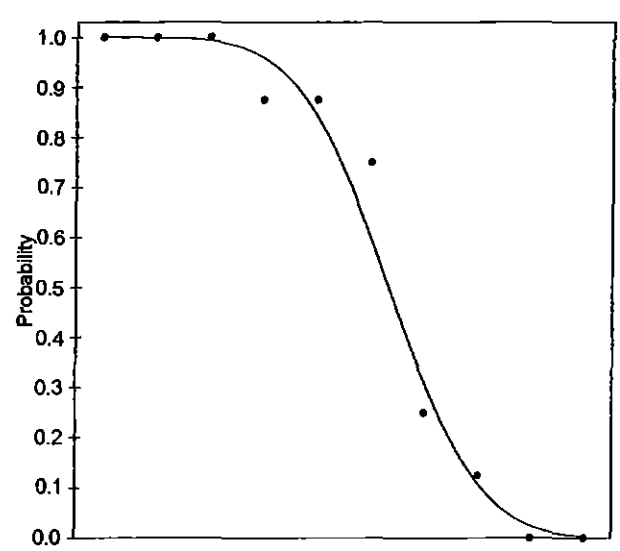

Figure 5.3.3.-I.

5.4. EXTENDED SIGMOID DOSE-RESPONSE CURVES

5.4.1. FOUR-PARAMETER LOGISTIC CURVE ANALYSIS

A serological assay of tetanus sera

As already stated in Section 3.4, this example is intended to illustrate a "possible" way to analyse the data presented, but not necessarily to reflect the "only" or the "most appropriate" way. Many other approaches can be found in the literature, but in most cases they should not yield dramatically different outcomes. A short discussion of

alternative approaches and other statistical considerations is given in Section 7.5.

A guinea-pig antiserum is assayed against a standard serum (0.4 IU/mL) using an enzyme-linked immunosorbent assay technique (ELISA). 10 two-fold dilutions of each serum were applied on a 96-well ELISA plate. Each dilution was applied twice. The observed responses are listed in Table 5.4.1.-I.

Table 5.4.1.-I. *Observed responses*

Standard S			Preparation to be examined T		
Dil.	Obs. 1	Obs. 2	Dil.	Obs. 1	Obs. 2
1/10	2.912	2.917	1/10	3.017	2.987
1/20	2.579	2.654	1/20	2.801	2.808
1/40	2.130	2.212	1/40	2.401	2.450
1/80	1.651	1.638	1/80	1.918	1.963
1/160	1.073	0.973	1/160	1.364	1.299
1/320	0.585	0.666	1/320	0.861	0.854
1/640	0.463	0.356	1/640	0.497	0.496
1/1280	0.266	0.234	1/1280	0.340	0.344
1/2560	0.228	0.197	1/2560	0.242	0.217
1/5120	0.176	0.215	1/5120	0.178	0.125

For this example, it will be assumed that the laboratory has validated conditions 1 to 3 in Section 3.1.1 when the assay was being developed for routine use. In addition, the laboratory has validated that the upper limit and lower limit of the samples can be assumed to be equal.

No unusual features are discovered in a graphical representation. A least squares method of a suitable computer program is used to fit the parameters of the logistic function, assuming that the residual error terms are independent and identically distributed normal random variables. In this case, 3 parameters (α, β and δ) are needed to describe the common slope-factor and the common lower and upper asymptotes. 2 additional parameters (γ_S and γ_T) are needed to describe the horizontal location of the 2 curves.

The following estimates of the parameters are returned by the program:

$\alpha = 3.196$ $\quad \gamma_S = -4.307$

$\beta = 1.125$ $\quad \gamma_T = -4.684$

$\delta = 0.145$

In addition, the estimated residual variance (s^2) is returned as 0.001429 with 20 degrees of freedom (within-treatments variation).

In order to obtain confidence limits, and also to check for parallelism and linearity, the observed responses (u) are linearised and submitted to a weighted parallel-line analysis by the program. This procedure is very similar to that described in Section 4.2 for probit analysis with the following modifications:

$$Y = \beta(x_I - \gamma)$$

$$\Phi = \frac{1}{1 + e^{-Y}}$$

$$Z = \frac{e^{-Y}}{(1 + e^{-Y})^2}$$

$$y = Y + \frac{\left(\frac{u-\delta}{\alpha-\delta}\right) - \Phi}{Z}$$

$$w = \frac{Z^2(\alpha-\delta)^2}{s^2}$$

The resulting weighted analysis of variance of the transformed responses (y) using weights (w) is shown in Table 5.4.1.-II.

Table 5.4.1.-II *Weighted analysis of variance*

Source of variation	Degrees of freedom	χ^2	Probability
Preparations	1	0.529653	0.467
Regression	1	6599.51	0.000
Non-parallelism	1	0.0458738	0.830
Non-linearity	16	8.89337	0.918
Treatments	19	6608.98	0.000
Residual error	20	20.0000	
Total	39	6628.98	

There are no significant deviations from parallelism and linearity and thus the assay is satisfactory for potency calculations. If the condition of equal upper and lower asymptotes is not fulfilled, significant deviations from linearity and/or parallelism are likely to occur because the tests for linearity and parallelism reflect the goodness of fit of the complete four-parameter model. The residual error in the analysis of variance is always equal to 1 as a result of the transformation. However, a heterogeneity factor (analogous to that for the probit model) can be computed.

The relative potency of the test preparation can be obtained as the antilogarithm of $\gamma_S - \gamma_T$. Multiplying by the assigned potency of the standard yields an estimate of 1.459 × 0.4 = 0.584 IU/mL. Formula 4.2.3.-2 gives 95 per cent confidence limits from 0.557-0.612 IU/mL.

6. COMBINATION OF ASSAY RESULTS

6.1. INTRODUCTION

Replication of independent assays and combination of their results is often needed to fulfil the requirements of the European Pharmacopoeia. The question then arises as to whether it is appropriate to combine the results of such assays and if so in what way.

Two assays may be regarded as mutually independent when the execution of either does not affect the probabilities of the possible outcomes of the other. This implies that the random errors in all essential factors influencing the result (for example, dilutions of the standard and of the preparation to be examined, the sensitivity of the biological indicator) in 1 assay must be independent of the corresponding random errors in the other one. Assays on successive days using the original and retained dilutions of the standard therefore are not independent assays.

There are several methods for combining the results of independent assays, the most theoretically acceptable being the most difficult to apply. Three simple, approximate methods are described below; others may be used provided the necessary conditions are fulfilled.

Before potencies from assays based on the parallel-line or probit model are combined they must be expressed in logarithms; potencies derived from assays based on the slope-ratio model are used as such. As the former models are more common than those based on the slope-ratio model, the symbol M denoting ln potency is used in the formulae in this section; by reading R (slope-ratio) for M, the analyst may use the same formulae for potencies derived from assays based on the slope-ratio model. All estimates of potency must be corrected for the potency assigned to the reference preparation before they are combined.

6.2. COMBINATION OF INDEPENDENT ASSAY RESULTS

This method can be used provided the following conditions are fulfilled:

1) the potency estimates are derived from independent assays;

2) for each assay C is close to 1 (say less than 1.1);

3) the number of degrees of freedom of the individual residual errors is not smaller than 6, but preferably larger than 15.

When these conditions are not fulfilled, an independent combination of the results cannot be applied. The method described in Section 6.3 may then be used to obtain the best estimate of the mean potency to be adopted in further assays as an assumed potency.

6.2.1. HOMOGENEITY OF POTENCY ESTIMATES

It is assumed that the results of each of the n' assays have been analysed to give n' values of M with associated confidence limits. For each assay the logarithmic confidence interval L is obtained by subtracting the lower limit from the upper. A weight W for each value of M is calculated from equation 6.2.1.-1, where t has the same value as that used in the calculation of confidence limits.

$$W = \frac{4t^2}{L^2} \qquad (6.2.1.\text{-}1)$$

By squaring the deviation of each value of M from the weighted mean, multiplying by the appropriate weight and summing over all assays, a statistic is obtained which is approximately distributed as χ^2 (see Table 8.3) and which may be used to test the homogeneity of a set of ln potency estimates:

$$\chi^2 \approx \sum_{n'} W(M - \overline{M})^2 \text{ where } \overline{M} = \frac{\sum WM}{\sum W} \qquad (6.2.1.\text{-}2)$$

If the calculated χ^2 is smaller than the tabulated value corresponding to $(n' - 1)$ degrees of freedom the potencies are homogeneous and the mean potency and limits obtained in Section 6.2.2 will be meaningful.

If the calculated value of this statistic is greater than the tabulated value, the potencies are heterogeneous. This means that the variation between individual estimates of M is greater than would have been predicted from the estimates of the confidence limits, i.e. that there is a significant variability between the assays. Under these circumstances the equations in Section 6.2.2 are no longer applicable. Instead, the formulae in Section 6.2.3 may be used.

6.2.2. WEIGHTED COMBINATION (BASED ON THE INTRA-ASSAY VARIATION)

The products WM are formed for each assay and their sum divided by the total weight for all assays to give the logarithm of the weighted mean potency.

$$\overline{M} = \frac{\sum WM}{\sum W} \qquad (6.2.2.\text{-}1)$$

The standard error of the ln (mean potency) is taken to be the square root of the reciprocal of the total weight:

$$s_{\overline{M}} = \sqrt{\frac{1}{\sum W}} \qquad (6.2.2.\text{-}2)$$

and approximate confidence limits are obtained from the antilogarithms of the value given by:

$$\overline{M} \pm t \times s_{\overline{M}} \qquad (6.2.2.\text{-}3)$$

where the number of degrees of freedom of t equals the sum of the number of degrees of freedom for the error mean squares in the individual assays.

6.2.3. SEMI-WEIGHTED COMBINATION (BASED ON THE INTRA- AND INTER-ASSAY VARIATION)

When results of several repeated assays are combined, the χ^2-value may be significant. The observed variation is then considered to have two components:

— the intra-assay variation:

$$s_M^2 = 1/W$$

— the inter-assay variation:

$$s_m^2 = \frac{\sum(M - \overline{M})^2}{(n' - 1)} - \frac{\sum s_M^2}{n'}$$

where M is the unweighted mean. The intra-assay variation varies from assay to assay whereas the inter-assay variation is common to all M.

For each M a weighting coefficient is then calculated as:

$$W' = \frac{1}{s_M^2 + s_m^2}$$

which replaces W in Section 6.2.2. where t is taken to be approximately 2.

Note: if s_m^2 is negative, then it is replaced by 0.

6.3. UNWEIGHTED COMBINATION OF ASSAY RESULTS

The method described below may be used when the conditions described in Section 6.2 are not fulfilled.

To combine the n' estimates of M from n' assays, the mean is calculated and an estimate of its standard error is obtained by calculating:

$$s_m^2 = \frac{\sum(M - \overline{M})^2}{(n' - 1)} - \frac{\sum s_M^2}{n'} \qquad (6.3.\text{-}1)$$

and the limits are:

$$\overline{M} \pm ts_{\overline{M}} \qquad (6.3.\text{-}2)$$

where t has $(n' - 1)$ degrees of freedom. The number n' of estimates of M is usually small, and hence the value of t is quite large.

6.4. EXAMPLE OF A WEIGHTED MEAN POTENCY WITH CONFIDENCE LIMITS

Table 6.4.-I lists 6 independent potency estimates of the same preparation together with their 95 per cent confidence limits and the number of degrees of freedom of their error variances. Conditions 1, 2 and 3 in Section 6.2. are met. The ln potencies and the weights are calculated as described in Section 6.2.

Table 6.4.-I. – *Potency estimates and confidence intervals of 6 independent assays*

Potency estimate (IU/vial)	Lower limit (IU/vial)	Upper limit (IU/vial)	Degrees of freedom	ln potency M	Weight W
18 367	17 755	19 002	20	9.8183	3777.7
18 003	17 415	18 610	20	9.7983	3951.5
18 064	17 319	18 838	20	9.8017	2462.5
17 832	17 253	18 429	20	9.7887	4003.0
18 635	17 959	19 339	20	9.8328	3175.6
18 269	17 722	18 834	20	9.8130	4699.5

Homogeneity of potency estimates is assessed with formula 6.2.1.-2 which gives a χ^2 of 4.42 with 5 degrees of freedom. This is not significant ($p = 0.49$) and thus, a weighted mean potency is calculated with formula 6.2.2.-1. which yields 9.8085.

Formula 6.2.2.-2 gives a standard error of 0.00673 and approximate 95 per cent confidence limits of 9.7951 and 9.8218 are calculated with formula 6.2.2.-3 where t has 120 degrees of freedom.

By taking the antilogarithms a potency of 18 187 IU/vial is found with 95 per cent confidence limits from 17 946-18 431 IU/vial.

7. BEYOND THIS ANNEX

It is impossible to give a comprehensive treatise of statistical methods in a pharmacopoeial text. However, the methods described in this annex should suffice for most pharmacopoeial purposes. This section tries to give a more abstract survey of alternative or more general methods that have been developed. The interested reader is encouraged to further explore the existing literature in this area. The use of more specialised statistical methods should, in any case, be left to qualified personnel.

7.1. GENERAL LINEAR MODELS

The methods given in this annex can be described in terms of general linear models (or generalised linear models to include the probit and logit methods). The principle is to define a linear structure matrix X (or design matrix) in which each row represents an observation and each column a linear effect (preparation, block, column, dose). For example: the Latin square design in example 5.1.2 would involve a matrix with 36 rows and 13 columns. 1 column for each of the preparations, 1 column for the doses, 5 columns for each block except the first, and 5 columns for each row except the first. All columns, except the one for doses, are filled with 0 or 1 depending on whether or not the observation relates to the effect. A vector Y is filled with the (transformed) observations. The effects are estimated with the formula $(X^TX)^{-1}X^TY$ from which the potency estimate m can easily be derived as a ratio of relevant effects. Confidence intervals are calculated from Fieller's theorem:

$$m_L,\ m_U = \frac{\left[m - \frac{gv_{12}}{v_{22}} \pm \frac{t}{b}\sqrt{v_{11} - 2mv_{12} + m^2v_{22} - g\left(v_{11} - \frac{v_{12}^2}{v_{22}}\right)}\right]}{(1-g)}$$

where $g = \frac{t^2s^2v_{22}}{b^2}$

and v_{11}, v_{22}, v_{12} represent the variance multipliers for the numerator, the denominator and their covariance multiplier respectively. These are taken directly from $(X^TX)^{-1}$ or indirectly by noting that:

$$Var(a_1 - a_2) = Var(a_1) + Var(a_2) - 2Cov(a_1, a_2)$$

and

$$Cov(a_1 - a_2, b) = Cov(a_1, b) - Cov(a_2, b)$$

A full analysis of variance in which all components are partitioned is slightly more complicated as it involves a renewed definition of X with more columns to relax the assumptions of parallelism and linearity, after which the linear hypotheses can be tested. For assays depending upon quantal responses the linear effects (intercepts a_S, a_T etc. and the common slope b are found by maximising the sum over treatments of $n\ln\Phi(a_i + bx) + (n - r)\ln(1 - \Phi(a_i + bx))$ where x is the ln(dose), Φ denotes the shape of the distribution and $i \in \{S, T, \ldots\}$.

7.2. HETEROGENEITY OF VARIANCE

Heterogeneity of variance cannot always be solved by simply transforming the responses. A possible way to cope with this problem is to perform a weighted linear regression. In order to obtain an unbiased estimate, the weight of the observations is taken to be proportional to the reciprocal of the error variances. Since the true error variance is not always known, an iterative reweighted linear procedure may be followed. However, the calculation of the confidence interval involves new problems.

7.3. OUTLIERS AND ROBUST METHODS

The method of least squares described in this annex has the disadvantage of being very sensitive to outliers. A clear outlier may completely corrupt the calculations. This problem is often remedied by discarding the outlying result from the dataset. This policy can lead to arbitrary rejection of data and is not always without danger. It is not easy to give a general guideline on how to decide whether or not a specific observation is an outlier and it is for this reason that many robust methods have been developed. These methods are less sensitive to outliers because they give less weight to observations that are far away from the predicted value. New problems usually arise in computing confidence intervals or defining a satisfactory function to be minimised.

7.4. CORRELATED ERRORS

Absolute randomisation is not always feasible or very undesirable from a practical point of view. Thus, subsequent doses within a dilution series often exhibit correlated errors leading to confidence limits that are far too narrow. Some methods have been developed that take account of this autocorrelation effect.

7.5. EXTENDED NON-LINEAR DOSE-RESPONSE CURVES

Analysis of extended non-linear dose-response curves raises a number of statistical questions which require consideration, and for which professional advice is recommended. Some of these are indicated below.

1) An example using the four-parameter logistic function has been shown. However, models based on functions giving other sigmoid curves may also be used. Models incorporating additional asymmetry parameters have been suggested.

2) Heterogeneity of variance is common when responses cover a wide range. If the analysis ignores the heterogeneity, interpretation of results may not be correct and estimates may be biased. Use of the reciprocal of the error variances as weights is unlikely to be reliable with limited numbers of replicates. It may be appropriate to estimate a function which relates variance to mean response.

3) The statistical curve-fitting procedures may give different estimates depending on assumptions made about the homogeneity of the variance and on the range of responses used.

4) In principle, equality of upper and lower response limits for the different preparations included in an assay can be directly tested in each assay. However, interpretation of the results of these tests may not be straightforward. The tests for linearity and parallelism given by the simplified method of analysis (Example 5.4.1) indirectly incorporate tests for equality and accuracy of upper and lower limits.

5) Many assays include "controls" which are intended to identify the upper and/or lower response limits. However, these values may not be consistent with the statistically fitted upper and lower response limits based on the extended dose-response curve.

6) The simplified method of analysis given in Example 5.4.1 provides approximate confidence intervals. Other methods may also be used, for example intervals based on lack-of-fit of the completely specified model. For typical assay data, with responses covering the complete range for each preparation tested, all methods give similar results.

7.6. NON-PARALLELISM OF DOSE-RESPONSE CURVES

Similarity of dose-response relationships is a fundamental criterion for assessing whether an assay may be regarded as a dilution assay and hence whether the estimation of relative potency is valid (see Section 3.1.1).

This criterion is frequently met by showing that dose-response curves for standard and test samples do not deviate significantly from parallelism. Underestimation of the residual error can lead to excess rejection of assays due to significant deviations from parallelism and/or linearity. This is often an artefact of inappropriate assay design or analysis. Minor modifications to assay designs might in many cases substantially improve the estimation of the residual error. Analysis allowing for the actual level of replication may also improve the situation, e.g. by accounting for multiple applications of the same dilution or correlation of errors between serial dilutions. If estimation of the relevant residual error is not feasible for individual assays, for example because it is impractical to create independent doses and/or replicates, it might be possible to obtain a more correct estimate of the residual error during the assay validation process. In such a case it may be justified to replace the residual error, estimated from the individual assay, by an average (pooled) residual error, determined during the validation process and agreed by the competent authorities.

Where not specified by relevant procedures, curve similarity may be assessed by another approach described as "equivalence testing", whereby, during the validation process, a range of the allowable difference between slopes or other measures of curve similarity, an equivalence acceptance criterion, is determined. If supported by appropriate documentation and agreed by the competent authorities, meeting the equivalence acceptance criteria may be used to satisfy the curve similarity requirement.

There may be cases where the assay system is sufficiently precise to detect genuine non-parallelism. If there is true non-parallelism this needs to be recognised and a suitable solution adopted. A solution might, for example, require a suitable standard that is similar in composition to, and therefore parallel to, the test samples. If the assay system is responding in a non-specific manner to extraneous components of the standard or test samples, then a more specific assay system that does not respond to the irrelevant components may be the solution. No simple, generally applicable statistical solution exists to overcome these fundamental problems. The appropriate action has to be decided on a case-by-case basis with the help of statistical expertise.

8. TABLES AND GENERATING PROCEDURES

The tables in this section list the critical values for the most frequently occurring numbers of degrees of freedom. If a critical value is not listed, reference should be made to more extensive tables. Many computer programs include statistical functions and their use is recommended instead of the tables in this section. Alternatively, the generating procedures given below each table can be used to compute the probability corresponding to a given statistic and number of degrees of freedom.

8.1. THE *F*-DISTRIBUTION

If an observed value is higher than the value in Table 8.1.-I, it is considered to be significant (upper lines, $p = 0.05$) or highly significant (lower lines, $p = 0.01$). *df*1 is the number of degrees of freedom of the numerator and *df*2 is the number of degrees of freedom of the denominator.

Generating procedure Let F be the *F*-ratio and df1 and df2 as described above. Let pi = π = 3.14159265358979... The procedure in Table 8.1.-II will then generate the *p*-value.

8.2. THE *t*-DISTRIBUTION

If an observed value is higher than the value in Table 8.2.-I, it is considered to be significant ($p = 0.05$) or highly significant ($p = 0.01$).

Table 8.2.-I *Critical values of the t-distribution*

df	$p = 0.05$	$p = 0.01$	df	$p = 0.05$	$p = 0.01$
1	12.706	63.656	22	2.074	2.819
2	4.303	9.925	24	2.064	2.797
3	3.182	5.841	26	2.056	2.779
4	2.776	4.604	28	2.048	2.763
5	2.571	4.032	30	2.042	2.750
6	2.447	3.707	35	2.030	2.724
7	2.365	3.499	40	2.021	2.704
8	2.306	3.355	45	2.014	2.690
9	2.262	3.250	50	2.009	2.678
10	2.228	3.169	60	2.000	2.660
12	2.179	3.055	70	1.994	2.648
14	2.145	2.977	80	1.990	2.639
16	2.120	2.921	90	1.987	2.632
18	2.101	2.878	100	1.984	2.626
20	2.086	2.845	∞	1.960	2.576

Generating procedures The *p*-value for a given *t* with df degrees of freedom can be found with the procedures in Section 8.1 where $F = t^2$, df1 = 1 and df2 = df.

Table 8.1.-I *Critical values of the F-distribution*

df1 → df2 ↓	1	2	3	4	5	6	8	10	12	15	20	∞
10	4.965	4.103	3.708	3.478	3.326	3.217	3.072	2.978	2.913	2.845	2.774	2.538
	10.044	7.559	6.552	5.994	5.636	5.386	5.057	4.849	4.706	4.558	4.405	3.909

	7.562	5.390	4.510	4.018	3.699	3.473	3.173	2.979	2.843	2.700	2.549	2.006
50	4.034	3.183	2.790	2.557	2.400	2.286	2.130	2.026	1.952	1.871	1.784	1.438
	7.171	5.057	4.199	3.720	3.408	3.186	2.890	2.698	2.563	2.419	2.265	1.683
∞	3.841	2.996	2.605	2.372	2.214	2.099	1.938	1.831	1.752	1.666	1.571	1.000
	6.635	4.605	3.782	3.319	3.017	2.802	2.511	2.321	2.185	2.039	1.878	1.000

Table 8.1.-II *Generating procedure for the F-distribution*

If df1 is even	If df1 is odd and df2 is even	If df1 and df2 are odd
x=df1/(df1+df2/F)	x=df2/(df2+df1*F)	x=atn(sqr(df1*F/df2))
s=1	s=1	ca=cos(x)
t=1	t=1	sn=sin(x)
for i=2 to(df1-2) step 2	for i=2 to(df2-2) step 2	x=x/2
t=t*x*(df2+i-2)/i	t=t*x*(df1+i-2)/i	s=0
s=s+t	s=s+t	t=sn*cs/2
next i	next i	v=0
p=s*(1-x)^(df2/2)	p=1-s*(1-x)^(df1/2)	w=1
		for i=2 to(df2-1) step 2
		s=s+t
		t=t*i/(i+1)*cs*cs
		next i
		for i=1 to(df1-2) step 2
		v=v+w
		w=w*(df2+i)/(i+2)*sn*sn
		next i
		p=1+(t*df2*v-x-s)/pi*4

The t-value ($p = 0.05$) for a given number of degrees of freedom df can be found with the procedure in Table 8.2.-II, which should be accurate up to 6 decimal places.

Table 8.2.-II *Generating procedure for the t-distribution*

```
t = 1.959964+
    2.37228/df+
    2.82202/df^2+
    2.56449/df^3+
    1.51956/df^4+
    1.02579/df^6+
    0.44210/df^7
```

8.3. THE χ^2-DISTRIBUTION

Table 8.3.-I *Critical values of the χ^2-distribution*

df	$p = 0.05$	$p = 0.01$	df	$p = 0.05$	$p = 0.01$
1	3.841	6.635	11	19.675	24.725
2	5.991	9.210	12	21.026	26.217
3	7.815	11.345	13	22.362	27.688
4	9.488	13.277	14	23.685	29.141
5	11.070	15.086	15	24.996	30.578
6	12.592	16.812	16	26.296	32.000
7	14.067	18.475	20	31.410	37.566
8	15.507	20.090	25	37.652	44.314
9	16.919	21.666	30	43.773	50.892
10	18.307	23.209	40	55.758	63.691

If an observed value is higher than the value in Table 8.3.-I, it is considered to be significant ($p = 0.05$) or highly significant ($p = 0.01$).

Generating procedure Let X2 be the χ^2-value and df as described above. The procedure in Table 8.3.-II will then generate the p-value.

Table 8.3.-II *Generating procedure for the χ^2-distribution*

If df is even	If df is odd
s=0	x=sqr(x2)
t=exp(-x2/2)	s=0
for i=2 to df step 2	t=x*exp(-x2/2)/sqr(pi/2)
s=s+t	for i=3 to df step 2
t=t*x2/i	s=s+t
next i	t=t*x2/i
p=1-s	next i
	p=1-s-2*phi(x)

In this procedure phi is the cumulative standard normal distribution function Φ (see Section 8.4).

8.4. THE Φ-DISTRIBUTION (THE CUMULATIVE STANDARD NORMAL DISTRIBUTION)

The Φ-value for negative x is found from Table 8.4.-I as $1 - \Phi(-x)$.

Table 8.4.-I *Values of the Φ-distribution*

x	Φ	x	Φ	x	Φ
0.00	0.500	1.00	0.841	2.00	0.977
0.05	0.520	1.05	0.853	2.05	0.980
0.10	0.540	1.10	0.864	2.10	0.982
0.15	0.560	1.15	0.875	2.15	0.984
0.20	0.579	1.20	0.885	2.20	0.986
0.25	0.599	1.25	0.894	2.25	0.988
0.30	0.618	1.30	0.903	2.30	0.989
0.35	0.637	1.35	0.911	2.35	0.991
0.40	0.655	1.40	0.919	2.40	0.992
0.45	0.674	1.45	0.926	2.45	0.993
0.50	0.691	1.50	0.933	2.50	0.994
0.55	0.709	1.55	0.939	2.55	0.995
0.60	0.726	1.60	0.945	2.60	0.995
0.65	0.742	1.65	0.951	2.65	0.996
0.70	0.758	1.70	0.955	2.70	0.997
0.75	0.773	1.75	0.960	2.75	0.997
0.80	0.788	1.80	0.964	2.80	0.997
0.85	0.802	1.85	0.968	2.85	0.998
0.90	0.816	1.90	0.971	2.90	0.998
0.95	0.829	1.95	0.974	2.95	0.998

Generating procedure Let x be the x-value.
The procedure in Table 8.4.-II will generate the corresponding Φ-value if $0 \leq x \leq 8.15$. If x is greater than 8.15 the Φ-value can be set to 1. If x is negative, the formula given above can be used. This procedure assumes that the computer can represent about 15 decimal places. If less digits or more digits can be represented, the procedure needs some trivial modifications.

Table 8.4.-II *Generating procedure for the Φ-distribution*

```
s=0
t=x
i=1
repeat
s=s+t
i=i+2
t=t*x*x/i
until t<1E-16
phi=0.5+s*exp(-x*x/2)/sqr(2*pi)
```

8.5. RANDOM PERMUTATIONS

Random permutations are needed in randomised block designs. The following algorithm shows how the built-in random generator of a computer can be used to create random permutations of N treatments.

Step 1. Write the N possible treatments down in a row.

Step 2. Obtain a random integer r such that $1 \leq r \leq N$.

Step 3. Exchange the r-th treatment with the N-th treatment in the row.

Step 4. Let $N = N - 1$ and repeat steps 2 to 4 until $N = 1$.

An example with 6 treatments will illustrate this algorithm.

1.	$N = 6$	S_1	S_2	S_3	T_1	T_2	T_3
2.	$r = 2$		→				←
3.		S_1	T_3	S_3	T_1	T_2	S_2
4.	$N = 5$						
2.	$r = 4$				→	←	
3.		S_1	T_3	S_3	T_2	T_1	S_2
4.	$N = 4$						
2.	$r = 4$				↓		
3.		S_1	T_3	S_3	T_2	T_1	S_2
4.	$N = 3$						
2.	$r = 1$	→		←			
3.		S_3	T_3	S_1	T_2	T_1	S_2
4.	$N = 2$						
2.	$r = 1$	→	←				
3.		T_3	S_3	S_1	T_2	T_1	S_2
4.	$N = 1$						

8.6. LATIN SQUARES

The following example shows how 3 independent permutations can be used to obtain a Latin square.

1) Generate a random permutation of the N possible treatments (see Section 8.5):

T_3	S_3	S_1	T_2	T_1	S_2

2) A simple Latin square can now be constructed by "rotating" this permutation to the right. This can be done as follows. Write the permutation found in step 1 down on the first row. The second row consists of the same permutation, but with all treatments shifted to the right. The rightmost treatment is put on the empty place at the left. This is repeated for all the rows until all the treatments appear once in each column:

T_3	S_3	S_1	T_2	T_1	S_2
S_2	T_3	S_3	S_1	T_2	T_1
T_1	S_2	T_3	S_3	S_1	T_2
T_2	T_1	S_2	T_3	S_3	S_1
S_1	T_2	T_1	S_2	T_3	S_3
S_3	S_1	T_2	T_1	S_2	T_3

3) Generate 2 independent random permutations of the figures 1 to N:
— one for the rows:

2	3	6	1	4	5

— and one for the columns:

3	4	6	2	5	1

4) The Latin square can now be found by sorting the rows and columns of the simple Latin square according to the 2 permutations for the rows and columns:

	3	4	6	2	5	1
2	T_3	S_3	S_1	T_2	T_1	S_2
3	S_2	T_3	S_3	S_1	T_2	T_1

9. GLOSSARY OF SYMBOLS

Symbol	Definition
a	Intersection of linear regression of responses on dose or ln (dose)
b	Slope of linear regression of responses on dose or on ln (dose)
d	Number of dose levels for each preparation (excluding the blank in slope-ratio assays)
e	Base of natural logarithms (= 2.71828182845905...)
g	Statistic used in Fieller's theorem: $g = \frac{C-1}{C}$
h	Number of preparations in an assay, including the standard preparation
m	Potency estimate obtained as a ratio of effects in general linear models
n	Number of replicates for each treatment
p	Probability of a given statistic being larger than the observed value. Also used as the ratio r/n in probit analysis
r	The number of responding units per treatment group in assays depending upon quantal responses
s	Estimate of standard deviation (= $\sqrt{s^2}$)
s^2	Estimate of residual variance given by error mean square in analysis of variance
t	Student's statistic (Table 8.2.)
u	Observed response in four-parameter analysis
v_{11}, v_{12}, v_{22}	(Co)variance multipliers for numerator and denominator of ratio m in Fieller's theorem
w	Weighting coefficient
x	The ln(dose)
y	Individual response or transformed response
A	Assumed potencies of test preparations when making up doses
B	Mean response to blanks in slope-ratio assays
C	Statistic used in the calculation of confidence intervals: $C = \frac{1}{1-g}$
$C_1, \ldots, C_n$	Mean response to each column of a Latin square design
D_1, D_2	Mean response on time 1 or time 2 in the twin cross-over design
F	Ratio of 2 independent estimates of variance following an F-distribution (Table 8.1.)
$G_S, G_T, \ldots$	Treatment values used in the analysis of variance for slope-ratio assays
H_P, H_L	Multipliers used in the analysis of variance for parallel-line assays
H_B, H_I	Multipliers used in the analysis of variance for slope-ratio assays
I	In parallel-line assays, the ln of the ratio between adjacent doses. In slope-ratio assays, the interval between adjacent doses
$J_S, J_T, \ldots$	Linearity values used in the analysis of variance for slope-ratio assays
K	Correction term used in the calculation of sums of squares in the analysis of variance
L	Width of confidence interval in logarithms
$L_S, L_T, \ldots$	Linear contrasts of standard and test preparations
M	ln potency
M'	ln potency ratio of a given test preparation
N	Total number of treatments in the assay (= dh)
$P_S, P_T, \ldots$	Sum of standard and test preparations
R	Estimated potency of a given test preparation
R'	Potency ratio of a given test preparation
$R_1, \ldots, R_n$	Mean response in each of rows 1 to n of a Latin square design, or in each block of a randomised block design
S	Standard preparation
$S_1, \ldots, S_d$	Mean response to the lowest dose 1 up to the highest dose d of the standard preparation S
SS	Sum of squares due to a given source of variation
$T, U, V, \ldots$	Test preparations
$T_1, \ldots, T_d$	Mean response to the lowest dose 1 up to the highest dose d of test preparation T
V	Variance coefficient in the calculation of confidence limits
W	Weighting factor in combination of assay results
X	Linear structure or design matrix used in general linear models
Y	Vector representing the (transformed) responses in general linear models
Z	The first derivative of Φ
α	Upper asymptote of the ln(dose)-response curve in four-parameter analysis
β	Slope-factor of the ln(dose)-response curve in four-parameter analysis
γ	The ln(dose) giving 50 per cent response in the four-parameter analysis
δ	Lower asymptote of the ln(dose)-response curve in four-parameter analysis
π	3.14159265358979323 8...
Φ	Cumulative standard normal distribution function (Table 8.4.)
χ^2	Chi-square statistic (Table 8.3.)

H. Materials Used in Chromatographic Tests

Introduction

In pharmacopoeial monographs elaborated by the British Pharmacopoeia Commission, the brand name of a TLC plate, a chromatographic column or column packing material that has been found to be suitable for the purpose is usually included in the text. The inclusion of such information does not imply that a different but equivalent commercial brand may not be used.

In monographs from the European Pharmacopoeia, references to commercial sources of, *inter alia*, TLC plates and chromatographic columns are not given. However, records of the materials used during development of the monograph are included when the draft monograph is published for comment in *Pharmeuropa*.

Liquid chromatographic tests

Defining an appropriate chromatographic system for liquid chromatographic tests is complicated by the existence of numerous variants of stationary phases, particularly amongst the chemically-bonded reverse phase materials for which not only brand to brand, but also occasionally batch to batch variations occur that can influence a separation. To assist analysts in the choice of column, the European Pharmacopoeia Commission has prepared a table of the characteristics of different types of octadecylsilyl stationary phases. The Table was published in the 3rd edition of the Technical Guide to the Elaboration of Monographs [special issue of *Pharmeuropa*; December 1999] and is reproduced below. The Table lists columns that have been widely used in the development of pharmacopoeial tests, but does not imply that a different but equivalent column cannot be used.

J. Control of Impurities in Substances for Pharmaceutical Use

(Ph. Eur. general texts 5.10)

Preamble

The monographs of the European Pharmacopoeia on substances for pharmaceutical use are designed to ensure acceptable quality for users. The role of the Pharmacopoeia in public health protection requires that adequate control of impurities be provided by monographs. The quality required is based on scientific, technical and regulatory considerations.

Requirements concerning impurities are given in specific monographs and in the general monograph *Substances for pharmaceutical use (2034)*. Specific monographs and the general monograph are complementary: specific monographs prescribe acceptance criteria for impurities whereas the general monograph deals with the need for qualification, identification and reporting of any organic impurities that occur in *active substances*.

The thresholds for reporting, identification and qualification contained in the general monograph *Substances for pharmaceutical use (2034)* apply to all related substances. However, if a monograph does not contain a related substances test based on a quantitative method, any new impurities occurring above a threshold may be overlooked since the test is not capable to detect those impurities.

The provisions of the Related substances section of the general monograph *Substances for pharmaceutical use (2034)*, notably those concerning thresholds, do not apply to excipients; also excluded from the provisions of this section are: biological and biotechnological products; oligonucleotides; radiopharmaceuticals; fermentation products and semi-synthetic products derived therefrom; herbal products and crude products of animal and plant origin. Although the thresholds stated in the general monograph do not apply, the general concepts of reporting, identification (wherever possible) and qualification of impurities are equally valid for these classes.

Basis for the elaboration of monographs of the European Pharmacopoeia

European Pharmacopoeia monographs are elaborated on substances that are present in medicinal products that have been authorised by the competent authorities of Parties to the *European Pharmacopoeia Convention*. Consequently, these monographs do not necessarily cover all sources of substances for pharmaceutical use on the world market.

Organic and inorganic impurities present in those substances that have been evaluated by the competent authorities are qualified with respect to safety at the maximum authorised content (at the maximum daily dose) unless new safety data that become available following evaluation justify lower limits.

European Pharmacopoeia monographs on substances for pharmaceutical use are elaborated by groups of experts and working parties collaborating with national pharmacopoeia authorities, the competent authorities for marketing authorisation, national control laboratories and the European Pharmacopoeia laboratory; they are also assisted by the producers of the substances and/or the pharmaceutical manufacturers that use these substances.

Control of impurities in substances for pharmaceutical use

The quality with respect to impurities is controlled by a set of tests within a monograph. These tests are intended to cover organic and inorganic impurities that are relevant in view of the sources of active substances in authorised medicinal products.

Control of residual solvents is provided by the general monograph *Substances for pharmaceutical use (2034)* and general chapter *5.4. Residual solvents*. The certificate of suitability of a monograph of the European Pharmacopoeia for a given source of a substance indicates the residual solvents that are controlled together with the specified acceptance criteria and the validated control method where this differs from those described in general chapter *2.4.24. Identification and control of residual solvents*.

Monographs on organic chemicals usually have a test entitled "Related substances" that covers relevant organic impurities. This test may be supplemented by specific tests where the general test does not control a given impurity or where there

Characteristics of Different Reverse-phase (C-18) Silica Columns for Liquid Chromatography

Name	Particle type	Particle size (µm)	Specific surface area (m^2/g)	Pore size (nm)	% Carbon	Endcapped	Base deactivated

Zorbax	Spherical	5	330	7.5	16	+	–

are particular reasons (for example, safety reasons) for requiring special control.

Where a monograph has no Related substances (or equivalent) test but only specific tests, the user of a substance must nevertheless ensure that there is suitable control of organic impurities; those occurring above the identification threshold are to be identified (wherever possible) and, unless justified, those occurring above the qualification threshold are to be qualified (see also under Recommendations to users of monographs of active substances).

Where the monograph covers substances with different impurity profiles, it may have a single related substances test to cover all impurities mentioned in the Impurities section or several tests may be necessary to give control of all known profiles. Compliance may be established by carrying out only the tests relevant to the known impurity profile for the source of the substance.

Instructions for control of impurities may be included in the Production section of a monograph, for example where the only analytical method appropriate for the control of a given impurity is to be performed by the manufacturer since the method is too technically complex for general use or cannot be applied to the final drug substance and/or where validation of the production process (including the purification step) will give sufficient control.

Impurities section in monographs on active substances

The Impurities section in a monograph includes impurities (chemical structure and name wherever possible), which are usually organic, that are known to be detected by the tests prescribed in the monograph. It is based on information available at the time of elaboration or revision of the monograph and is not necessarily exhaustive. The section includes specified impurities and, where so indicated, other detectable impurities.

Specified impurities Have an acceptance criterion not greater than that authorised by the competent authorities.

Other detectable impurities Are potential impurities with a defined structure but not known to be normally present above the identification threshold in substances used in medicinal products that have been authorised by the competent authorities of Parties to the Convention. They are given in the Impurities section for information.

Where an impurity other than a specified impurity is found in an active substance it is the responsibility of the user of the substance to check whether it has to be identified/qualified, depending on its content, nature, maximum daily dose and relevant identification/qualification threshold, in accordance with the general monograph on *Substances for pharmaceutical use (2034)*, Related substances section.

It should be noted that specific thresholds are applied to substances exclusively for veterinary use.

Interpretation of the test for related substances in the monographs on active substances

A specific monograph on a substance for pharmaceutical use is to be read and interpreted in conjunction with the general monograph on *Substances for pharmaceutical use (2034)*.

Where a general acceptance criterion for impurities ("any other impurity", "other impurities", "any impurity") equivalent to a nominal content greater than the applicable identification threshold (see the general monograph on *Substances for pharmaceutical use (2034)*) is prescribed, this is valid only for specified impurities mentioned in the Impurities section. The need for identification (wherever possible), reporting, specification and qualification of other impurities that occur must be considered according to the requirements of the general monograph. It is the responsibility of the user of the substance to determine the validity of the acceptance criteria for impurities not mentioned in the Impurities section and for those indicated as other detectable impurities.

Acceptance criteria for the related substances test are presented in different ways in existing monographs; the decision tree (Figure 5.10.-1) may be used as an aid in the interpretation of general acceptance criteria and their relation with the Impurities section of the monograph.

General acceptance criteria for "other" impurities are expressed in various ways in the monographs: "any other impurity", "other impurities", "any impurity", "any spot", "any band", etc. The general acceptance criteria may apply to certain specified impurities only or to unspecified impurities and certain specified impurities, depending on the nature of the active substance and the applicable identification threshold. Pending editorial adaptation of already published monographs using unequivocal terminology, the decision tree (Figure 5.10.-1) may be used to determine the acceptance criterion to be applied.

Recommendations to users of monographs of active substances

Monographs give a specification for suitable quality of substances with impurity profiles corresponding to those taken into account during elaboration and/or revision of the monograph. It is the responsibility of the user of the substance to check that the monograph provides adequate control of impurities for a substance for pharmaceutical use from a given source, notably by using the procedure for certification of suitability of the monographs of the European Pharmacopoeia.

A monograph with a related substances test based on a quantitative method (such as liquid chromatography, gas chromatography and capillary electrophoresis) provides adequate control of impurities for a substance from a given source if impurities present in amounts above the applicable identification threshold are specified impurities mentioned in the Impurities section.

If the substance contains impurities other than those mentioned in the Impurities section, it has to be verified that these impurities are detectable by the method described in the monograph, otherwise a new method must be developed and revision of the monograph must be requested. Depending on the contents found and the limits proposed, the identification and/or the qualification of these impurities must be considered.

Where a single related substances test covers different impurity profiles, only impurities for the known profile from a single source need to be reported in the certificate of analysis unless the marketing authorisation holder uses active substances with different impurity profiles.

Identification of impurities (peak assignment)

Where a monograph has an individual limit for an impurity, it is often necessary to define means of identification, for example using a reference substance, a representative chromatogram or relative retention. The user of the substance may find it necessary to identify impurities other than those for which the monograph provides a means of identification, for example to check the suitability of the specification for a given impurity profile by comparison with the Impurities section. The European Pharmacopoeia does not provide reference substances, representative chromatograms or information on relative retentions for this purpose, unless prescribed in the monograph. Users will therefore have to apply the available scientific techniques for identification.

New impurities/Specified impurities above the specified limit

Where a new manufacturing process or change in an established process leads to the occurrence of a new impurity, it is necessary to apply the provisions of the general monograph on *Substances for pharmaceutical use (2034)* regarding identification and qualification and to verify the suitability of the monograph for control of the impurity. A certificate of suitability is a means for confirming for a substance from a given source that the new impurity is adequately controlled or the certificate contains a method for control with a defined acceptance criterion. In the latter case revision of the monograph will be initiated.

Where a new manufacturing process or change in an established process leads to the occurrence of a specified impurity above the specified limit, it is necessary to apply the provisions of the general monograph on *Substances for pharmaceutical use (2034)* regarding qualification.

Expression of acceptance criteria

The acceptance criteria for related substances are expressed in monographs either in terms of comparison of peak areas (comparative tests) or as numerical values.

Chromatographic methods

General chapter *2.2.46. Chromatographic separation techniques* deals with various aspects of impurities control.

Information is available via the EDQM website on commercial names for columns and other reagents and equipment found suitable during monograph development, where this is considered useful.

GLOSSARY

Disregard limit

In chromatographic tests, the nominal content at or below which peaks/signals are not taken into account for calculating a sum of impurities. The numerical values for the disregard limit and the reporting threshold are usually the same.

Identification threshold

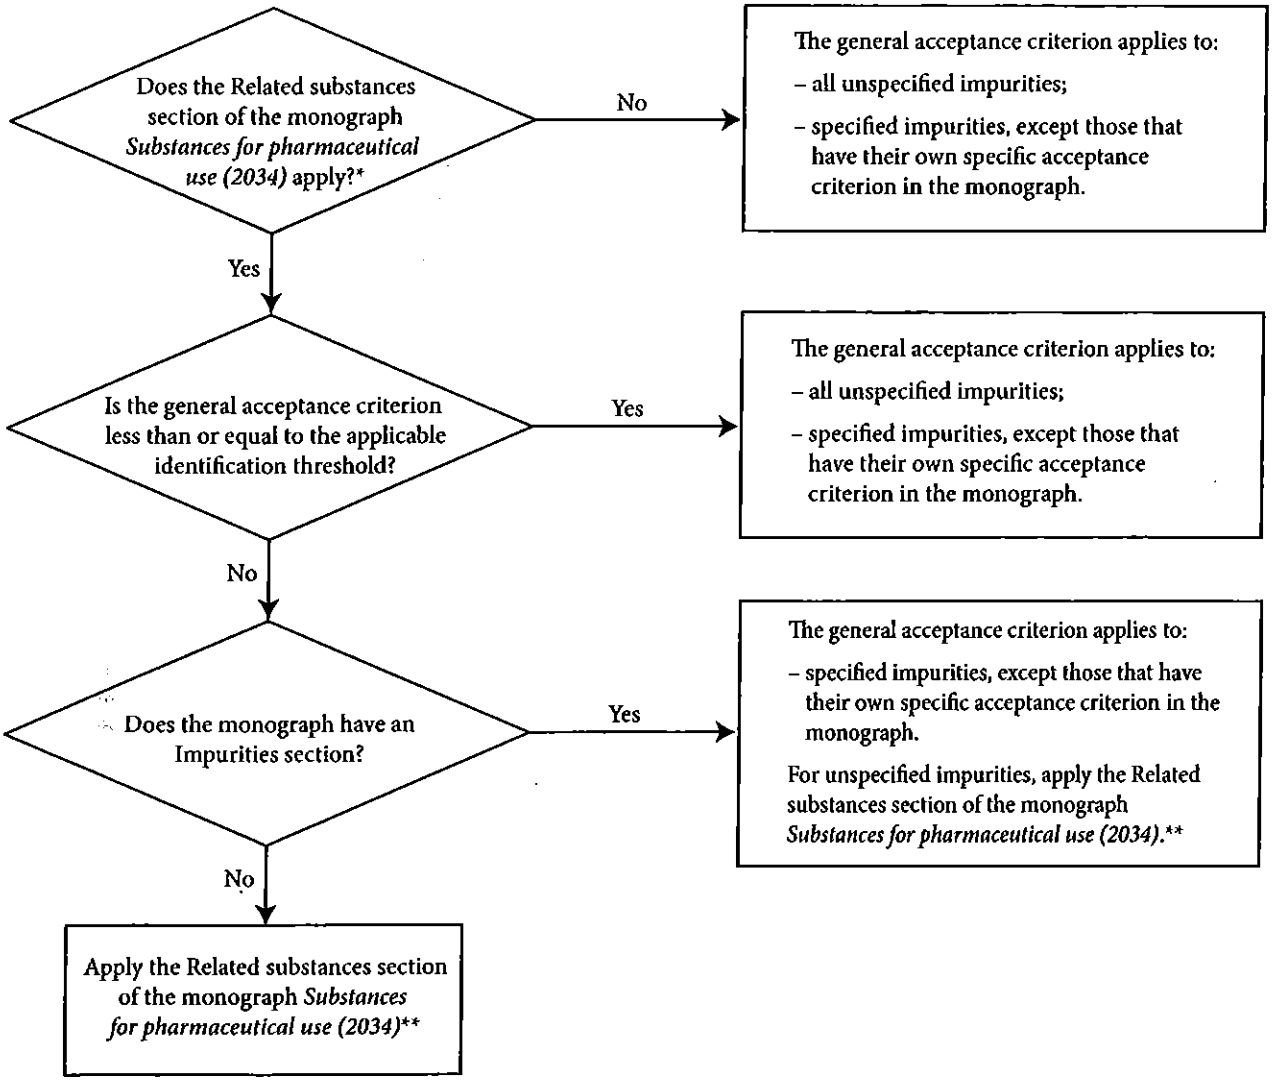
A limit above which an impurity is to be identified.

Identified impurity

An impurity for which structural characterisation has been achieved.

Impurity

Any component of a substance for pharmaceutical use that is not the chemical entity defined as the substance.



* The requirements of this section apply to active substances with the exception of: biological and biotechnological products; oligonucleotides; radiopharmaceuticals; products of fermentation and semi-synthetic products derived therefrom; crude products of animal or plant origin; herbal products.

** To apply the Related substances section of the monograph *Substances for pharmaceutical use (2034)*:
- an individual acceptance criterion must be defined for any impurity that may be present above the identification threshold;
- any impurity with an acceptance criterion above the identification threshold must wherever possible be identified;
- any impurity with an acceptance criterion above the qualification threshold must be qualified.

Figure 5.10.-1. – *Decision tree for interpretation of general acceptance criteria for 'other' impurities in monographs*

Nominal concentration
Concentration calculated on the basis of the concentration of the prescribed reference and taking account of the prescribed correction factor.

Other detectable impurities
Potential impurities with a defined structure that are known to be detected by the tests in a monograph but not known to be normally present above the identification threshold in substances used in medicinal products that have been authorised by the competent authorities of Parties to the Convention. They are unspecified impurities and are thus limited by a general acceptance criterion.

Potential impurity
An impurity that theoretically can arise during manufacture or storage. It may or may not actually appear in the substance. Where a potential impurity is known to be detected by the tests in a monograph but not known to be normally present in substances used in medicinal products that have been authorised by the competent authorities of Parties to the Convention, it will be included in the Impurities section under *Other detectable impurities* for information.

Qualification
The process of acquiring and evaluating data that establishes the biological safety of an individual impurity or a given impurity profile at the level(s) specified.

Qualification threshold
A limit above which an impurity is to be qualified.

Related substances
Title used in monographs for general tests for organic impurities.

Reporting threshold
A limit above which an impurity is to be reported. Synonym: reporting level.

Specified impurity
An impurity that is individually listed and limited with a specific acceptance criterion in a monograph. A specified impurity can be either identified or unidentified.

Unidentified impurity
An impurity for which a structural characterisation has not been achieved and that is defined solely by qualitative analytical properties (for example, relative retention).

Unspecified impurity
An impurity that is limited by a general acceptance criterion and not individually listed with its own specific acceptance criterion.

K. Characters Section in Monographs

(Ph. Eur. general texts 5.11)

The General Notices indicate that the statements included in the Characters section are not to be interpreted in a strict sense and are not requirements. For information of users, the methods recommended to authors of monographs as the basis for statements concerning hygroscopicity, crystallinity and solubility are given below.

HYGROSCOPICITY

This method is to be carried out on a substance that complies with the test for loss on drying or water content of the monograph. The method gives an indication of the degree of hygroscopicity rather than a true determination.

Use a glass weighing vessel 50 mm in external diameter and 15 mm high. Weigh the vessel and stopper (m_1). Place the amount of substance prescribed for the test for loss on drying or water in the vessel and weigh (m_2). Place the unstoppered vessel in a desiccator at 25 °C containing a saturated solution of ammonium chloride or ammonium sulfate or place it in a climatic cabinet set at 25 ± 1 °C and 80 ± 2 per cent relative humidity. Allow to stand for 24 h. Stopper the weighing vessel and weigh (m_3).

Calculate the percentage increase in mass using the expression:

$$\frac{m_3 - m_2}{m_2 - m_1} \times 100$$

The result is interpreted as follows:
- *deliquescent*: sufficient water is absorbed to form a liquid,
- *very hygroscopic*: increase in mass is equal to or greater than 15 per cent,
- *hygroscopic*: increase in mass is less than 15 per cent and equal to or greater than 2 per cent,
- *slightly hygroscopic*: increase in mass is less than 2 per cent and equal to or greater than 0.2 per cent.

CRYSTALLINITY

This method is employed to establish the crystalline or amorphous nature of a substance.

Mount a few particles of the substance to be examined in mineral oil on a clean glass slide. Examine under a polarising microscope. Crystalline particles exhibit birefringence and extinction positions when the microscope stage is revolved.

SOLUBILITY

For this test a maximum of 111 mg of substance (for each solvent) and a maximum of 30 mL of each solvent are necessary.

Dissolving procedure
Shake vigorously for 1 min and place in a constant temperature device, maintained at a temperature of 25.0 ± 0.5 °C for 15 min. If the substance is not completely dissolved, repeat the shaking for 1 min and place the tube in the constant temperature device for 15 min.

Method
Weigh 100 mg of finely powdered substance (90) (*2.9.12*) in a stoppered tube (16 mm in internal diameter and 160 mm long), add 0.1 mL of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *very soluble*.

If the substance is not completely dissolved, add 0.9 mL of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *freely soluble*.

If the substance is not completely dissolved, add 2.0 mL of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *soluble*.

If the substance is not completely dissolved, add 7.0 mL of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *sparingly soluble*.

If the substance is not completely dissolved, weigh 10 mg of finely powdered substance (90) (*2.9.12*) in a stoppered tube, add 10.0 mL of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *slightly soluble*.

If the substance is not completely dissolved, weigh 1 mg of finely powdered substance (90) (*2.9.12*) in a stoppered tube, add 10.0 mL of the solvent and proceed as described under Dissolving Procedure. If the substance is completely dissolved, it is *very slightly soluble*.

L. Alternative Methods for Control of Microbiological Quality

(Ph. Eur. general texts 5.1.6)

The following chapter is published for information.

1 GENERAL INTRODUCTION

The objective of this chapter is to facilitate the implementation and use of alternative microbiological methods where this can lead to efficient microbiological control and improved assurance for the quality of pharmaceutical products.

The microbiological methods described in the European Pharmacopoeia have been used for over a century and these methods for detecting, enumerating and identifying micro-organisms still serve microbiologists well. Over the years, these methods have been invaluable for the production of microbiologically safe pharmaceutical products. However, these microbiological methods are slow, and in the case of sterility tests, results are not available before an incubation period of 14 days. Consequently, the results from these methods seldom enable proactive corrective action to be taken.

Alternative methods for the control of microbiological quality have shown potential for real-time or near real-time results with the possibility of earlier corrective action. These new methods, if validated and adapted for routine use, can also offer significant improvements in the quality of testing.

Alternative methods may be used for in-process samples of pharmaceutical products, particularly for the application of Process Analytical Technology (PAT), for environmental monitoring and for industrial utilities (e.g. production and distribution of water, steam etc.), thereby contributing to the quality control of these products.

In this chapter, alternative microbiological methods for pharmaceutical application are described. For each method, the basic principle is stated and the advantages and disadvantages of the method are discussed along with any critical aspects to be considered. Potential uses that may be envisaged based on the principles of the method concerned are given, but it is not intended to suggest that such applications have been realised or that the list provided is exhaustive.

It is not the intention of this chapter to recommend one method over another, nor is it the intention to provide an exclusive or exhaustive list of alternative methods that can be used for pharmaceutical microbiological control.
The information herein may be used, however, in the process of choosing an alternative microbiological method as a supplement or as an alternative to pharmacopoeial microbiological methods and to give guidance on validation of the chosen method. If a suitable method is described in the Pharmacopoeia, this method is the reference method.
In this rapidly developing field, other methods are likely to appear and the guidance offered herein may be equally applicable in these cases.

There are 3 major types of determination specific to microbiological tests:
— qualitative tests for the presence or absence of micro-organisms;
— quantitative tests for enumeration of micro-organisms;
— identification tests.

1-1 QUALITATIVE TESTS FOR THE PRESENCE OR ABSENCE OF MICRO-ORGANISMS

In conventional microbiological analysis, this type of test is characterised by the use of turbidity or other growth-related changes in a culture medium as evidence of the presence of viable micro-organisms in the test sample. The most common example of this test is the test for sterility (*2.6.1*). Other examples include those tests designed to evaluate the presence or absence of a particular type of viable micro-organism in a sample. The conventional sterility test may be replaced by, for example, tests based on bioluminescence or solid phase cytometry, gas detection or autofluorescence. Nucleic acid amplification techniques (NAT) (*2.6.21*) may also be used for the detection of mycoplasmas (*2.6.7*).

1-2 QUANTITATIVE TESTS FOR ENUMERATION OF MICRO-ORGANISMS

Membrane filtration and plate count methods are conventional methods used to estimate the number of viable micro-organisms present in a sample. The Most Probable Number (MPN) method is another example of such methods and was developed as a means of estimating the number of viable micro-organisms present in a sample not amenable to direct plating. Examples of alternative methods for enumeration include autofluorescence, flow cytometry, direct epifluorescent filter technique (DEFT) and solid phase cytometry.

1-3 IDENTIFICATION TESTS

Biochemical and morphological characterisation of an unknown micro-organism is the classical approach to identification. Recently developed methods have streamlined and automated aspects of this identification, especially in the areas of data handling, analysis and storage. Several alternative approaches that have been integrated into these methods include biochemical reactions, carbon substrate utilisation, characterisation of fatty acid composition, mass spectroscopy and Raman spectroscopy, restriction endonuclease banding patterns and the use of genome sequencing methods such as 16S rRNA gene sequence analysis for prokaryotes.

Traditional biochemical and phenotypic techniques have been shown to be less accurate and precise than genotypic methods.

Pure cultures are required for a precise identification and such cultures must be fresh and cultivated in appropriate media.

Databases are part of the systems and are included in the primary validation. As identification methods depend on the use of databases, the extent of coverage of the database with respect to the range of micro-organisms of interest must be taken into account during validation. Appropriate software allows customisation of the database, thereby allowing the user to add micro-organisms not previously included. This possibility must be considered during the validation.

2 GENERAL PRINCIPLES OF ALTERNATIVE METHODS

Alternative microbiological methods employ direct and indirect methods of detection; in some instances amplification of the signal is achieved by enrichment methods. In recognition of these differences, and for convenience within this chapter, alternative methods for the control of microbiological quality are divided into 3 categories:
— growth-based methods, where a detectable signal is usually achieved by a period of culture;
— direct measurement, where individual cells are differentiated and/or imaged;
— cell component analysis, where the expression of specific cell components offers an indirect measure of microbial presence and identification of micro-organisms.

In some instances, these distinctions are artificial, but enable a working classification to be created.

2-1 GROWTH-BASED METHODS

2-1-1 General critical aspects of methods based on early detection of growth

Such methods are critically dependent on microbial growth in order to provide an indication of the presence and/or number of micro-organisms. For the typically low levels of microbial contamination seen in pharmaceutical products, detection may take 24 h or longer. Increased sensitivity can be achieved with filtered products. In this case, after filtration, the membrane filter is incubated in or on the medium and the result is expressed as presence or absence in the quantity corresponding to the filtered volume. These systems, if they use an incubation step in liquid media, do not offer quantitative information, but a presence/absence determination in the quantity analysed. Analysis of more than one sample quantity may offer a semi-quantitative estimation (limit test). The major benefit of early detection methods compared to classical methods is often the capacity to simultaneously process a large number of samples and the potential to obtain a result in a shorter time.

The methods described below can be used for quantitative, semi-quantitative or qualitative analyses. They are also non-destructive, therefore subsequent identification of the micro-organism is possible.

2-1-2 Electrochemical methods

Principles of measurement Micro-organisms multiplying and metabolising in appropriate growth media produce highly charged ionic metabolites from weakly charged organic nutrients leading to the modification of electrical properties in such media. These changes in impedance (measured by conductance or capacitance) are monitored with electrodes included in the culture vessels and in contact with the culture medium. The measurable end-point is the time taken to detect a predetermined impedance change; for particular types of micro-organisms, the detection time is inversely proportional to the initial inoculum size. For yeasts and moulds, which only produce small changes in electrical impedance, an indirect measurement of conductance can be used. Direct measurement of capacitance can also be carried out.

Critical aspects There is no direct relationship between the original microbial level and the detectable end-point.

Potential uses Microbiological assay of antibiotics, efficacy of antimicrobial preservation and presence/absence testing.

2-1-3 Measurement of consumption or production of gas

Principles of measurement Appropriate growth media is utilised by actively multiplying and metabolising micro-organisms, leading to the production of metabolites or the elimination of specific nutrients. These methods detect microbial growth either by changes in the electrical properties of a sensor in response to a change in gas composition or by colorimetric changes of a sensor in response to physico-chemical changes in the growth medium in contact with that sensor. The systems are based on non-destructive techniques which enable subsequent identification or strain typing of the micro-organisms. Bacteria and/or fungi may be grown in closed containers and continuous monitoring can be performed using automated instruments that measure gas evolution (e.g. CO_2) or consumption (e.g. O_2) as surrogate markers of microbial growth. Furthermore, the production of metabolites or elimination of nutrients can lead to changes in pH or redox potential. All of these changes can be measured either directly or indirectly as changes in colorimetric markers in the growth medium.

Critical aspects There is no direct relationship between the original microbial level and the detectable end-point. The incubation temperature, the physiological state and type of micro-organism, the initial load and the algorithm for data processing can significantly affect the results or the time to detection.

Potential uses Presence/absence testing of filterable or non-filterable samples (e.g. final drug products, in-process control samples, media fill or container closure integrity testing).

2-1-4 Bioluminescence

Principles of measurement Adenosine triphosphate (ATP) is a well-documented marker of cell viability. In this method, ATP first needs to be released from the micro-organisms using an appropriate extractant, followed by an assay using the luciferin/luciferase enzyme system, which emits light in proportion to the ATP present. The signal-to-noise ratio can be increased by addition of ADP and converting this ADP into released ATP.

Qualitative method: micro-organisms are cultivated in liquid medium. The emitted light is measured with a bioluminometer and is expressed in relative light units (RLU) (e.g. bioluminescence in a tube or a well of a microtitre plate). The RLU obtained from the sample is compared with a pre-determined threshold value. The result is positive if the RLU obtained with the analysed sample exceeds the threshold value.

Quantitative method: micro-organisms are captured on a membrane and cultivated by incubation on agar medium. Using a charge coupled device (CCD) camera, the ATP released from microcolonies can be detected by light emission and a quantitative determination is possible.

Critical aspects If the sample has a high level of bacterial contamination, the detection is rapid. For low levels of contamination, it is necessary to increase the number of micro-organisms using an incubation step in culture media (liquid or solid). The yield of ATP varies from one micro-organism to another and can depend on several factors including the species, the growth phase of the cell, the nutritional status, the cellular stress or the cellular age. Additional factors such as turbidity, sample colour or product matrix effects can also influence bioluminescence measurements. Extraction of ATP is generally a destructive process which should be considered with respect to any subsequent need for identification of detected micro-organisms.

Potential uses Presence/absence testing of filterable or non-filterable samples (e.g. final drug products, in-process control samples, media fill), total aerobic microbial count (TAMC), environmental and water monitoring, testing for efficacy of antimicrobial preservation.

2-1-5 Turbidimetry

Principles of measurement Microbial growth leads to detectable changes in medium opacity, which can be accurately quantified by optical density measurements at a specified wavelength. In its simplest form, such measurements are performed using a standard spectrophotometer, generally over a wavelength range of 420-615 nm. Alternative automated systems employ microtitre plate readers offering a continuous readout with early detection of optical density change.

Critical aspects Attempts have been made to extrapolate the initial microbial contamination from the time to detection, but this is limited to healthy micro-organisms with reproducible growth characteristics.

Potential uses By means of calibration graphs, determination of the inoculum size of microbial suspensions for use in pharmacopoeial tests. In automated mode, microbiological assay of antibiotics and testing for efficacy of antimicrobial preservation.

2-1-6 Growth detection using selective and/or indicative media

Principles of measurement The ability to detect the presence of specific enzymes using suitable chromogenic substrates has led to the development of a large number of methods for the identification of micro-organisms employing either manual or automated techniques. The incorporation of such substrates into a selective or non-selective primary isolation medium can eliminate the need for further subculture and biochemical testing for the identification of certain micro-organisms. Consequently, chromogenic liquid or solid culture media are designed to reveal specific enzymatic activities for detection and differentiation of micro-organisms. In these particular media, defined substrates are

introduced into the formulation and are metabolised by the specific cell enzyme of a given bacterium or fungus during growth. These substrates, which are linked to coloured indicators, are chosen according to the diagnostic enzymatic activity sought. Furthermore, chromogenic broth can be used for early or improved detection of contamination (e.g. in media fill or broth-based detection methods).

The use of innovative media presents several advantages, namely improved discrimination of colonies in a mixed culture, ease of use and ease of interpretation. In addition, response times are shorter as the growth and identification of the micro-organism are simultaneous.

Critical aspects Validation of the media must be undertaken carefully to ensure a combination of specificity, selectivity and robustness. The quality of the signal is based not only on the careful choice of the enzymes or indicators used as the basis of detection (as these enzymes may be present in different micro-organism genera), but also on the physico-chemical characteristics of the medium, e.g. pH.

Potential uses Detection of specified micro-organisms and qualitative testing (e.g. media fill and container closure integrity testing) and quantitative testing (e.g. water testing).

2-2 DIRECT MEASUREMENT

2-2-1 Solid phase cytometry

Principles of measurement Micro-organisms are stained for viability by exposure to a conjugated, initially non-fluorogenic, fluorophore. An intact cellular membrane is required to retain and accumulate the fluorophore within the cytoplasm. Inside metabolically-active microbial cells, the conjugate is enzymatically cleaved and the fluorescent derivative is released intracellularly. Micro-organisms are collected on a membrane filter either before or after viability staining.

Membrane surfaces retaining vital-stained cells are then scanned by a laser beam and epifluorescent excitation allows the detection of single, viable fluorescent micro-organisms. Appropriate software allows differentiation of viable micro-organisms from autofluorescent particles. The high sensitivity and rapidity of the method permit detection of microbial contaminants within a few hours. Total cell counts (viable and non-viable) can be obtained using fluorescent staining.

Critical aspects Metabolically active, fastidious and viable non-culturable micro-organisms can all be detected. This may result in reappraisal of the microbial limits established for the samples under evaluation. Spores require initiation of germination to enable detection. Single cell detection may be achievable, but identification of isolates might not be possible. False positives may occur due to autofluorescent particles that can be difficult to differentiate from micro-organisms. Signal discrimination and enhancement can be aided by microcolony growth.

Potential uses Rapid and sensitive method for the non-specific evaluation of microbial contamination.

2-2-2 Flow cytometry

Principles of measurement Fluorophore-labelled micro-organisms can be detected in suspension as they pass through a flow cytometer. Viable micro-organisms can be differentiated from non-viable particles by use of a viability-indicating fluorophore (see 2-2-1). The cell suspension stream is dispersed into a narrow channel and exposed to a laser which excites the fluorophore. Micro-organisms and particles are then counted in different channels depending on whether or not they contain a fluorescent cell.

Critical aspects Direct flow cytometry may be applied to the microbiological analysis of both filterable and non-filterable materials, and after possible enrichment in the case of the low contamination levels. It gives near real-time detection, but is not as sensitive as solid phase cytometry. To increase sensitivity for use in the pharmaceutical field, it is often necessary to add an incubation step in culture media, in which case the method becomes a combination of a growth-based method and a direct detection method. Particle size and number may have a significant effect on performance, and samples may require serial dilution. With the exception of filterability, similar considerations to those in solid phase cytometry apply. Clumping of bacteria can be a problem (e.g. *Staphylococcus aureus*).

Potential uses In contrast to solid phase cytometry, this method offers the potential to detect and enumerate microbial contamination in materials containing particulate matter and if the material cannot be filtered. If a pre-incubation step is needed, the method becomes a qualitative determination.

2-2-3 Direct epifluorescent filtration technique (DEFT)

Principles of measurement This technique may be considered a forerunner of solid phase cytometry. Micro-organisms, concentrated by filtration of the sample, are stained with a fluorescent dye (formerly acridine orange and now more commonly 4′,6-diamidino-2-phenylindole (DAPI)), that can be detected by epifluorescent illumination. Fluorescent vital staining techniques, as employed in solid phase cytometry (see 2-2-1), are amenable to DEFT, and fluorescent redox dyes such as 5-cyano-2,3-ditolyltetrazolium chloride (CTC) can be used to highlight respiring cells. Coupled with microscopy, the method allows rapid detection of micro-organisms with an absolute sensitivity that is dependent on the volume of product filtered and the number of fields of view examined. Semi-automated auto-focusing systems coupled to image analysis have served to improve the utility of this method. A modification of the principle involves sampling using an adhesive sheet (which permits collection of cells from surfaces), subsequent staining on the sheet itself, followed by direct observation using an epifluorescence microscope.

Critical aspects The distribution of micro-organisms on the membrane affects method robustness. The intensity of fluorescence can be influenced by the staining process and the metabolic status of the micro-organisms. Fluorescence is not necessarily an indicator of viability. A brief period of culture on the filter surface prior to staining allows microcolony formation; these microcolonies stain readily, can be easily enumerated and are demonstrable evidence of viability.

Potential uses DEFT is generally limited to low viscosity fluids, although pre-dilution or pre-filtration has occasionally been applied to viscous or particulate products. Monitoring of microbial contamination has been successfully applied to aqueous pharmaceuticals.

2-2-4 Autofluorescence

Principles of measurement The presence of endogenous autofluorescent molecules and metabolites (e.g. NADPH, flavoproteins) within micro-organisms allows the early detection and quantitative enumeration of microcolonies or single cells. For direct measurements, the laser-induced autofluorescence of a single micro-organism is captured by a detector, while for growth-based systems, automated sequential imaging of the membrane surface on agar medium over the incubation period is employed and image overlay

allows differentiation of growing microcolonies from fluorescent particulates. The emitted light is detected by a CCD camera. Non-destructive detection allows identification of contaminants at the end of the incubation period.

Critical aspects For a non-growth based measurement, viable, but non-culturable, micro-organisms might be detected. It may be difficult to distinguish between culturable micro-organisms, viable but non-culturable micro-organisms and/or other particles.

Potential uses Environmental monitoring, filterable in-process samples, water testing and product release for both sterile and non-sterile applications.

2-3 CELL COMPONENT ANALYSIS

2-3-1 Phenotypic techniques

2-3-1-1 Immunological methods

Principles of measurement Antibody-antigen reactions can be employed to detect unique cellular determinants of specific micro-organisms. These reactions can be linked to agglutination phenomena and colorimetric or fluorimetric end-points, which offer both quantitative and qualitative detection. Enzyme-linked immunosorbent assays (ELISA) offer simple solid-phase methodologies.

Critical aspects Immunological detection methods depend on the unique expression of specific identifiers, but do not necessarily demonstrate the presence of viable micro-organisms.

Potential uses Detection and identification of specified micro-organisms.

2-3-1-2 Fatty acid profiles

Principles of measurement The fatty acid composition of micro-organisms is stable, well conserved and shows a high degree of homogeneity within different taxonomic groups. The isolate is grown on a standard medium and harvested. The fatty acids are saponified, methylated and extracted, and the occurrence and amount of the resulting fatty acid methyl esters are measured using high-resolution gas chromatography. The fatty acid composition of an unknown isolate is compared with a database of known isolates for a possible match and identification.

Critical aspects The use of fatty acid profiles for microbial identification requires a high degree of standardisation. It is critical for the fatty acid composition of microbial cells that isolates are grown using standardised media and standard incubation conditions. Standard conditions for operation of the gas chromatograph must also be employed, with frequent runs of calibration standards and known isolates being very important.

Potential uses Identification or characterisation of environmental and product microbial contamination (for contaminant tracing and detection of specified micro-organisms).

2-3-1-3 Fourier transform infrared (FTIR) spectroscopy

Principles of measurement A Fourier transformation of the infrared spectrum of whole micro-organisms gives a stable, recognisable pattern typical of the taxonomic groups of micro-organisms. The analysis of the FTIR pattern can be performed with commercially available instruments.
The isolate is grown on a standard medium and harvested. Cell mass is transferred to a carrier, and the infrared spectrum is recorded. The Fourier transformation is calculated and the pattern is compared with a database of known isolates for a possible match and identification.

Critical aspects The use of FTIR patterns for microbial identification requires a high degree of standardisation. It is critical for the FTIR pattern of microbial cells that isolates are grown using standardised media and standard incubation conditions. The cells must be in the same state of the growth cycle when analysed, and particular attention must be paid to this in the validation process.

Potential uses Identification or characterisation of environmental and product microbial contamination (for contaminant tracing and detection of specified micro-organisms).

2-3-1-4 Mass spectrometry

Principles of measurement Ionised particles released by exposing microbial isolates to a laser in a vacuum can be analysed by mass spectrometry, providing characteristic spectra. Similarly, intact microbial cells, when subject to intense ionisation under matrix-assisted laser desorption ionisation-time of flight (MALDI-TOF) mass spectrometry, release a distinctive pattern of charged species. Such spectra can be compared with known profiles.

Critical aspects The isolates must be cultured under standardised conditions prior to analysis.

Potential uses Identification or characterisation of environmental and product microbial contaminants (for contaminant tracing and detection of specified micro-organisms).

2-3-1-5 Biochemical assays based on physiological reactions

Principles of measurement Systems capable of performing biochemical assays based on physiological reactions are used for the identification of micro-organisms. In the presence of a pure colony, the five basic steps for these assays are preparation, inoculation, incubation, readings and interpretation. These steps are usually preceded by a description of the colony morphology, a differentiation test (e.g. Gram stain), a description of the cellular morphology and/or other early biochemical differentiation tests (e.g. oxidase, catalase, coagulase) in order to determine the appropriate testing protocol.

The Gram stain is often a key characteristic upon which further testing is based. Alternatives to the traditional staining method include the potassium hydroxide (KOH) string test, the aminopeptidase test, a fluorescent staining method and a limulus amoebocyte lysate (LAL) based assay. Test kits are available for the latter 3 methods. The fluorescent staining method requires a fluorescence microscope or a flow cytometer.

Microbial cell suspensions are tested using biochemical (assimilation or susceptibility) test kits (plates or strips). Anaerobic and aerobic micro-organisms develop characteristic reactions to selected biochemical substances. They are also known to utilise specific carbon, nitrogen, phosphorus and sulfur sources or to be inhibited by a specific concentration of an antimicrobial agent. The results are based on measurable changes (e.g. turbidity, chromogenic or fluorogenic reaction) due to the growth or inhibition of the micro-organism under investigation. Comparison of the metabolic and/or antimicrobial resistance profile with a database allows for identification of the culture. These methods can be performed manually or by semi- or fully automated instruments. Complementary tests can be performed in cases of poor discrimination. Subcultures can help in cases of indeterminate results.

Critical aspects A fresh physiological culture is required. The performance of the system is also dependent on the selected phenotypic parameters, which must be stable, significant and in sufficient number.

Potential uses Identification or characterisation of environmental and product microbial contamination (for contaminant tracing and detection of specified micro-organisms).

2-3-2 Genotypic techniques

Identification and detection of micro-organisms as well as characterisation of strains belonging to the same species may be achieved by direct detection of nucleotide target sequences that are unique for a particular microbial species or microbial group, and are targets of the genotypic (DNA or RNA-based) detection techniques. These detection techniques may be separated into 3 broad categories: direct hybridisation, nucleic acid amplification and genetic fingerprinting.

2-3-2-1 Direct hybridisation

General principles of measurement DNA probes are short, labelled, single-strand segments of DNA that hybridise with a complementary region of microbial DNA or RNA. The probe or target DNA is usually labelled with either radioactive, fluorescent or chromogenic molecules in order to provide a hybridisation signal. Hybridisation assays include fluorescence *in situ* hybridisation (FISH) and microarray-based techniques.

General critical aspects Hybridisation generally requires a large amount of the target DNA for analysis, which may result in lower detection sensitivity. The availability of suitable probes may be limited.

Potential uses Due to the high specificity of the sequence-based hybridisation reaction, this method may be used for both detection and identification of micro-organisms.

2-3-2-2 Nucleic acid amplification techniques (NAT)

General principles of measurement NAT relies on the reiteration of the DNA polymerisation process, leading to an exponential increase of a specific nucleic acid fragment. The polymerase chain reaction (PCR) is the most widely used method for target DNA amplification. In this cyclic process, a specific DNA fragment is copied by a thermostable DNA polymerase enzyme in the presence of nucleotides and oligonucleotide primers, previously designed to flank the target sequence and to hybridise with it (see also general chapter *2.6.21*). After PCR, the amplified nucleic acid targets can be analysed using several methods of post-amplification analysis: fragment size analysis in gel electrophoresis, DNA sequencing or specific detection by hybridisation with a fluorescent-labelled probe. Real-time PCR eliminates the need for further post-amplification processing and offers the additional advantage that the likelihood of cross-contamination is minimised. An important advantage of real-time PCR is the ability to quantify the starting amount of the DNA target sequence in the original sample, in contrast to conventional PCR techniques, which are based on end-point detection. Since the amount of PCR product detected at the beginning of the exponential phase of the amplification reaction correlates with the initial starting amount of the DNA target, modern real-time PCR techniques have been developed to measure this exponential phase of the reaction. Automated real-time PCR systems are commercially available. For identification of species, either species-specific probes or primers can be used.

RNA can also be amplified by both conventional and real-time PCR after transcription into cDNA using a reverse transcriptase enzyme. This technique is known as reverse transcriptase PCR (RT-PCR) and it enables detection and identification of RNA viruses or viable organisms. Alternatively, specific RNA-based amplification techniques, for example nucleic acid sequence-based amplification or transcription-mediated amplification, are available. Both techniques produce RNA amplicons, in contrast to PCR which only produces DNA amplicons, even when starting from an RNA target.

Types of target to be amplified Regardless of the type of NAT used, the specificity of the test is determined by the target DNA sequence under evaluation.

For identification/characterisation purposes, the 16S or 23S ribosomal RNA genes may be used as targets. The 16S rRNA gene is an evolutionary-conserved gene present in all bacterial species, and is a broad range target as it is a universal marker for bacterial detection. The 23S rRNA gene is not widely used as a single target, but the 16S-23S rRNA transcribed intergenic spacer regions can be employed to distinguish between certain closely related species and/or to identify subtypes. Alternative broad-range targets include the *groEL* and *tuf* genes. Apart from broad-range targets, species-specific sequences can be used as targets for micro-organism identification. Depending on the species, either specific surface antigens, virulence factors or genes which code toxins may be amplified to detect and identify micro-organisms.

General critical aspects:

- the target and the primers chosen must be specific for a particular micro-organism or group of micro-organisms;
- the sensitivity of the methods is highly dependent on the efficiency of the lysis protocol and how successfully the DNA targets can be purified and concentrated in the sample;
- the presence of inhibitors of the enzymatic process results in false negative reactions;
- the procedures are prone to cross-contamination from background DNA resulting in false positive results.

Depending on the aim, a choice must be made between amplification of either a DNA or an RNA target, as this target choice affects the correlation with viability.

DNA targets are generally more widely used for identification purposes, but the use of DNA as a marker has the disadvantage that dead micro-organisms can also be detected. As mRNA is rapidly degraded in dead cells, it is considered a marker for viability. Furthermore, mRNA is the obligatory target for the identification of RNA viruses.

Critical aspects of (semi-) quantitative detection by real-time PCR Quantification of the target requires generation of appropriate standards and the use of standardised procedures.

Critical aspects of RT-PCR RNA is less stable compared to DNA, so it requires more attention during processing. Depending on the quality of the RNA isolation, the efficiency of the cDNA synthesis can vary. RT-PCR can be used to specifically detect RNA if DNA contamination of the RNA sample is low.

Critical aspects of using the 16S or 23S rRNA gene as a target for species identification 16S rRNA gene sequencing is a valuable method for identification of bacteria provided that appropriate universal primers from databases are selected. Its discriminatory power depends on the variability and the length of the 16S rRNA gene within a certain species. Regarding the use of assays targeting the 16S-23S rRNA intergenic spacer regions, the choice of appropriate species-specific primers/probes is of critical

importance due to the potential polymorphism of such regions.

Potential uses of NAT Due to the high sensitivity and specificity of amplification techniques, they are suitable for both detection and identification of micro-organisms. Real-time PCR is needed for quantitative or semi-quantitative analysis of the target. Besides quantitative determinations, the real-time PCR technique allows simultaneous detection of multiple targets in a single sample, as long as appropriate primers and probes that allow for multiplexing are employed. The sequencing of different genes (e.g.16S rDNA, 23S rDNA, rpoB, Gyr) is best applied to the identification of micro-organisms.

2-3-2-3 Genetic fingerprinting

Principles of measurement Genetic fingerprinting is the identification of a strain on the basis of its DNA profile (or RNA for RNA viruses). Individual DNA profiles may be different due to genetic diversity between strains of the same species, and the aim of the fingerprinting methods is to discriminate between these strains. The classical genetic fingerprinting technique characterises micro-organisms using restriction fragments of chromosomal DNA from bacterial and fungal genomes.

Different strains from the same species may exhibit different patterns and these differences are referred to as restriction fragment length polymorphisms (RFLPs). As cutting the chromosomal DNA with restriction enzymes generates too many fragment bands to be efficiently and accurately compared, several modifications of the conventional RFLP-based method have been developed. Examples of the kind of technologies used are ribotyping, pulsed-field gel electrophoresis (PFGE) and amplified fragment length polymorphism (AFLP). Several other fingerprinting methods use PCR to selectively amplify defined subsets of DNA restriction fragments from the entire genome, for example random amplified polymorphic DNA (RAPD) and variable number tandem repeats (VNTR).

Critical aspects All fingerprinting techniques require that the micro-organism is present as a pure culture. Depending on the method, a preliminary enrichment cultivation step may be necessary if a defined quantity or a specific DNA preparation is required for the test, e.g. AFLP and PFGE. The discriminatory power, the reproducibility, the expertise needed and the labour-burden vary among techniques. The major criticism of conventional RFLP analysis is the complexity of the banding patterns. The discriminatory power of ribotyping (based on patterns of rRNA genes) is less than that of PFGE (based on patterns of the whole genomic DNA) or some PCR-based methods, but it has the advantage that it can be a highly automated system. Although PFGE is one of the most highly discriminatory fingerprinting methods, it is time-consuming and technically demanding in the laboratory as it is not automated. It also requires the use of standardised protocols. AFLP has high reproducibility, but requires technical expertise and the interpretation of results may need automated computer analysis. The reproducibility of RAPD may be poor, so it must be performed in a standardised way.

Potential uses Genetic fingerprinting methods are mainly used for strain discrimination (characterisation below species level). They are a powerful tool for investigating and tracing the source and the spread of microbial contamination.

3 VALIDATION OF ALTERNATIVE MICROBIOLOGICAL METHODS

3-1 INTRODUCTION

Validation, whilst subject to a variety of context-specific definitions, can be generally defined as a method to establish documented evidence that a process will consistently achieve its intended goal. Therefore, to validate an alternative microbiological method, it is essential to understand and define what the procedure is intended to achieve.

Typically, pharmaceutical microbiological methods use specific characteristics of micro-organisms as indicators or detection principles in order to determine microbiological quality. The information generally sought is presence/absence, number, viability and/or identity of micro-organisms in a given product or environment. Any given method will usually provide an indirect and conditional measure of microbiological quality. For example, the total number and viability of micro-organisms can be indicated by the number of colonies appearing under a certain set of conditions of sample preparation, cultivation and incubation; reproduction in classical microbiology is hence taken as the general indicator for viability. There are other parameters, however, that can be used as a viability measure, such as the level of ATP or the accumulation or metabolism of substrates in living cells. The results from different viability-indicating methods may not always be identical; micro-organisms may not be able to reproduce on a given medium, but may still accumulate and metabolise a substrate. Conversely, micro-organisms may be unable, at a given state of damage, to accumulate a substrate, but may still be able to recover and reproduce.

Similar considerations arise with the multiplicity of methods used for identification of micro-organisms. Therefore, while characterisation of the pattern of metabolic activity is frequently used for species identification, alternative methods also exist. Again, the outcomes obtained may not be fully consistent for the different identification methods, as one answer may be appropriate for the construction of a correct phylogenetic correlation tree, while another may be more useful in the context of pathogenicity or other property of the differentiated micro-organisms.

3-2 VALIDATION PROCESS

Two levels of validation must be envisaged for the application of alternative microbiological methods, namely primary validation and validation for the intended use. The supplier of the alternative technology typically performs primary validation of a method, whereas validation for the intended use, which is a verification of the suitability or applicability of the method in a given situation, must be seen as the responsibility of the user.

Where specific equipment is critical for the application of a method, the equipment, including computer hardware and software, must be fully qualified.

3-2-1 Description of the technique

In order to characterise a specific microbiological method, the principle of detection must be clearly described by the supplier. Through primary validation, the method must be fully detailed with respect to the conditions required for application, the materials and equipment needed and the expected signal. The user shall critically review the available information.

3-2-2 Risk-benefit analysis

For validation of specific alternative microbiological methods, it is critical that the purpose of the quality assurance procedure is precisely outlined, as this defines the type and

depth of information needed. The information obtained by, and the limitations of, the pharmacopoeial method and the alternative method must be considered and compared in a risk-benefit analysis.

The risk level in adopting an alternative method varies depending on the technology considered, the methodology it replaces, the nature of the measurements taken (qualitative, quantitative or identification), the particular product or process attribute being evaluated, the location of the measurement in the manufacturing process chain and various other factors.

Risk analysis tools may be utilised in order to determine which alternative method is to be implemented, to assist in the justification of its implementation or to better understand the impact of implementation on production and/or product quality. An alternative method can be justified for use if the information obtained gives a scientifically sound measure of microbiological quality, and if the limitations of the method are not more severe than those of the pharmacopoeial method.

3-2-3 Primary validation

The supplier, using a panel of test micro-organisms appropriate for the intended use, must characterise the principle of detection. Depending on the type of alternative method, relevant validation criteria shall be selected from those listed below:

— prerequisite treatment of sample or micro-organisms;
— type of response;
— specificity;
— detection limit;
— quantitation limit;
— range;
— linearity;
— accuracy and precision;
— robustness of the method in a model system.

3-2-4 Validation for the intended use

Validation for the intended use should encompass the entire process, from the decision to change any aspects of a microbiological testing programme to on-going routine use. It should consist of the following phases:

— user requirement specification (URS);
— design qualification (DQ);
— installation qualification (IQ);
— operational qualification (OQ);
— performance qualification (PQ).

The supplier and user have different tasks to perform with regard to the validation and implementation of an alternative method. These tasks are summarised in Table 5.1.6.-1.

Table 5.1.6.-1 – *Tasks to be undertaken during the validation process*

Activity	Normally carried out by	
	Supplier	User
Primary validation	+	-(1)
URS (instrument, application)	-	+
Description of the technique	+	-(2)
Risk benefit analysis	-(3)	+
Design qualification (DQ)	-	+
Installation qualification (IQ)	-(4)	+
Operational qualification (OQ)	-(4)	+
Performance qualification (PQ):		
- verification of primary validation data given by the supplier;	-	+
- verification for the intended use (e.g. sterility testing, TAMC/TYMC, ...);	-	+
- method suitability test	-	+

(1) The user performs primary validation if they employ the alternative method for a use other than that defined by the supplier.
(2) The user shall critically review information provided by the supplier.
(3) As part of commercialisation, the supplier may list advantages of the alternative method over pharmacopoeial techniques.
(4) IQ/OQ for complex equipment, IQ/OQ is often outsourced to supplier.

3-2-4-1 User requirement specification (URS)

The URS describes the functions that the method must be capable of performing and will form the basis of the method selection process. It is an essential document, as acceptance testing will be based on the requirements detailed therein. It is important to consider data management capabilities at this stage, particularly within a regulatory context. The URS shall at least address the following items:

— application of the instrument:
  — the type of analysis to be performed (e.g. quantitative, semi-quantitative, qualitative or identification).
— detection limit or quantitation limit (sensitivity):
  — the detection limit may be linked to time to detection (TTD);
  — the required level of sensitivity, which will depend on the current specification, the dilution regime and the test sample size for the existing test method under replacement.
— specificity:
  — the ability of the alternative test method to selectively detect the micro-organisms or classes of micro-organisms; this should be based on historical data generated from the pharmacopoeial test method and complemented by information from the supplier of the alternative method;
  — the ability to detect only the required viable micro-organisms;
  — for identification methods, the extent of coverage of the database with respect to the range of micro-organisms of interest.
— number and type of samples:
  — the nature of samples to be tested and the manufacturing output per batch or work-shift.
— time to detection (TTD) or time to result (TTR):

— the TTD or TTR is an important attribute for alternative microbiological methods; for monitoring purposes, a relatively short TTD (e.g. a few hours) allows corrective actions to be taken at an early stage; for quality control purposes, a short TTD may be less critical.

— data management capabilities:
  — the new instrumentation may need to have laboratory information management system (LIMS) interface capability and external server compatibility, and the data management tools should be defined; evidence of software validation and functional testing reports will be required to support each part of the software and firmware functions.

3-2-4-2 Design qualification (DQ)

The DQ provides documented evidence that the design of any associated equipment is suitable for correct performance of the method. Most alternative method systems are based on commercial off-the-shelf equipment. The DQ is most suitably performed, therefore, by the instrument developer/manufacturer. Nevertheless, the user shall verify that the equipment meets the specifications laid down in the URS for the intended application.

3-2-4-3 Installation qualification (IQ)

The IQ provides documented evidence that the equipment has been provided and installed in accordance with its specifications.

3-2-4-4 Operational qualification (OQ)

The OQ provides documented evidence that the installed equipment operates within predetermined limits when used in accordance with its operational procedures.

3-2-4-5 Performance qualification (PQ)

The PQ provides documented evidence that the method, with the equipment installed and operated according to operational procedures, consistently performs in accordance with predetermined criteria and thereby yields correct results for the method. This is typically done with a panel of micro-organisms (e.g. pharmacopoeial test strains, in-house isolates or stressed/slow-growing micro-organisms). This assures that the conditions employed by the user laboratory make it possible to satisfy the criteria described by the supplier of the method in the model system used for the primary validation.

Verification of primary validation data given by the supplier (see 3-2-3). The method is verified using the panel of test micro-organisms given by the corresponding pharmacopoeial chapter. The alternative method must be applied according to the specified procedure of the supplier, without the samples to be analysed under the responsibility of the user, and must be shown to give comparable results as characterised in the model system used by the supplier.

Verification for the intended use (e.g. sterility testing, total aerobic microbial count (TAMC)/total combined yeasts/moulds count (TYMC), etc) The following points, where applicable, should be addressed:

— compatibility of the response with the sample preparation that the user normally performs for product testing (method suitability testing);
— limit and range of detection of the method with regard to sample size and sample availability;
— specificity of the response with regard to the influence of the product ingredients;
— linearity of the response with regard to the types of samples to be analysed;
— accuracy and precision of the response with regard to the types of samples to be analysed.

Acceptance criteria for the method will need to be defined as a function of the application and the validation data.

3-3 TYPES OF MICROBIOLOGICAL TESTS

Validation of a microbiological method is the process whereby it is experimentally established by the user that the performance characteristics of the method meet the requirements of the intended application. As microbiological tests have 3 basic applications (qualitative, quantitative and identification), 3 separate sets of validation criteria are required. These criteria are described below and summarised in Table 5.1.6.-2.

Table 5.1.6.-2 – *Validation criteria for qualitative, quantitative and identification tests*

Criterion	Qualitative test	Quantitative test	Identification test
Accuracy	+(1)	+	+
Precision	-	+	-
Specificity	+	+	+
Detection limit	+	-(2)	-
Quantitation limit	-	+	-
Linearity	-	+	-
Range	-	+	-
Robustness	+	+	+
Suitability testing	+	+	-
Equivalence testing	+	+	-

(1) Performing an accuracy test of the alternate method with respect to the pharmacopoeial method can be used instead of the validation of the limit of detection test.
(2) May be needed in some cases.

3-3-1 Validation of alternative qualitative tests for the presence or absence of micro-organisms

3-3-1-1 Specificity

The specificity of an alternative qualitative method is its ability to detect only the required micro-organisms, i.e. does not generate false positive results. This can be demonstrated using a panel of appropriate micro-organisms. Where relevant for the purpose of the test, mixtures of micro-organisms are used during validation. For qualitative methods that rely on growth to demonstrate presence or absence of micro-organisms, specificity is adequately addressed by demonstrating the growth promotion properties of the media. For those methods that do not require growth as an indicator of microbial presence, the specificity assures that extraneous matter in the test system does not interfere with the test.

3-3-1-2 Detection Limit

The detection limit of an alternative qualitative method is the lowest number of micro-organisms in a sample that can be detected under the stated analytical conditions.
A microbiological limit test determines the presence or absence of micro-organisms in a defined quantity of the sample under test. Due to the nature of microbiological tests, the detection limit reflects the number of micro-organisms present in the original sample before any dilution or incubation steps. The detection limit of the alternative method must not be a number greater than that of the pharmacopoeial method.

It is essential that the detection limit is determined using a sufficient number of replicates and a number of independent determinations.

3-3-1-3 Robustness

The robustness of an alternative qualitative method is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters (e.g. incubation period or incubation temperature range). Robustness is a validation parameter best suited to determination by the supplier of the method. Nevertheless, if the user modifies critical parameters, any effect on robustness must be evaluated. Robustness of a qualitative method is judged by its ability to detect the test micro-organisms after deliberate variations to the method parameters.

3-3-1-4 Suitability testing

The alternative method must be applied according to the specified procedure and with the samples to be analysed under the responsibility of the user. It must be shown that the test sample does not interfere with the system's detection capacity or microbial recovery. Specific points to be addressed are:

— the ability of the test to detect micro-organisms in the presence of the sample matrix;
— verifying if the sample matrix interferes with the alternative system (e.g. background signal or inhibiting chemical reactions).

Acceptance criteria for the method in routine use will need to be defined as a function of the application and the validation data.

3-3-1-5 Equivalence testing

Equivalence testing of 2 qualitative methods can be conducted directly on the validation parameters. This approach requires an adequate comparison experiment at low levels of inoculation (e.g. less than 5 CFU) with sufficient numbers of replicates for relevant strains of test micro-organisms. Alternatively, and in some cases additionally, equivalence testing can be carried out by the parallel testing of a predefined number of samples or for a predefined period of time. This parallel testing can be justified based on a risk assessment. The alternative method must enable an unequivocal decision as to whether compliance with the standards of the monographs would be achieved if the official method was used.

3-3-2 Validation of alternative quantitative tests for enumeration of micro-organisms

3-3-2-1 Accuracy

The accuracy of an alternative quantitative method is the closeness of the test results obtained by the alternative method to those obtained by the pharmacopoeial method. Accuracy must be demonstrated across the practical range of the test. It is usually expressed as the percentage recovery of micro-organisms by the alternative method compared to the percentage recovery using the pharmacopoeial method, taking into account statistical analysis.

Accuracy may be shown by preparing and testing a suspension of micro-organisms at the upper end of the test range and serially diluting to the lower end of the test range. For example, if the alternative method is meant to replace the pharmacopoeial plate count method for viable counts, then a reasonable range might be 10^0-10^6 CFU/mL.
If instead, it is a replacement for the MPN method, a much narrower range may be used. At least 1 suspension for each test micro-organism dilution must be analysed.

The alternative method should be shown to recover at least as many micro-organisms as the pharmacopoeial method using appropriate statistical analysis.

The protocol used to check the linearity of the method (see 3-3-2-5) may also be used to check the accuracy.
The suspensions of micro-organisms prepared for the alternative method are counted at the same time using the pharmacopoeial method.

3-3-2-2 Precision

The precision of an alternative quantitative method is the degree of agreement between individual test results when the procedure is applied repeatedly to multiple samplings of homogeneous suspensions of micro-organisms under the prescribed conditions. Precision should be split into repeatability and intermediate precision under normal or routine operating conditions. Repeatability (also referred to as within-run variability) refers to the use of the microbiological method with the same sample (replicate) in the same laboratory over a short period of time with the same analyst and the same equipment. It gives the minimum variability of the method. Intermediate precision (includes run-to-run variability and within-run variability) refers to the use of the microbiological method applied to different sample preparations of the product under test in the same laboratory with different analysts, equipment and/or on different days. It gives the maximum variability of the method.
The precision of a microbiological method is usually expressed as the standard deviation or relative standard deviation (coefficient of variation). At least 1 suspension in the middle of the test range is analysed. The number of replicates is chosen so that the entire test can be carried out during the same working session, i.e. under the same operating conditions and without any change in the suspension of micro-organisms. For intermediate precision, other working sessions are then carried out under conditions of maximum variability (different reagents, operators and/or days, etc.). The variance in the results observed in each of the working sessions is calculated. If the variances are homogeneous, the variance of the repeatability can be calculated. The inter-group variance of the results is also calculated and the resultant variance of the intermediate precision is given as the sum of the variance of the repeatability and the inter-group variance. The coefficient of variation is then calculated. Alternative methods must demonstrate precision comparable to that of the pharmacopoeial methods.

3-3-2-3 Specificity

The specificity of an alternative quantitative method is its ability to quantify only the required micro-organisms, i.e. does not generate false positive results. This may be demonstrated using a panel of appropriate micro-organisms. Where relevant for the purpose of the test, mixtures of micro-organisms are used during validation. For those methods that do not require growth as an indicator of microbial presence, the specificity assures that extraneous matter in the test system does not interfere with the test.

3-3-2-4 Quantitation limit

The quantitation limit of an alternative quantitative method is the lowest number of CFUs in a sample which can be quantitatively determined with suitable precision and accuracy. It is essential that the quantitation limit is determined from a number of replicates. The results of the linearity and accuracy studies can also be used. In this case, the lowest concentration in the linear range is considered to be the quantitation limit of the method. The quantitation

limit of the alternative method must not be greater than that of the pharmacopoeial method.

3-3-2-5 Linearity

The linearity of an alternative quantitative method is its ability (within a given range) to produce results that are proportional to the concentration of micro-organisms present in the sample. The linearity must be determined over a reasonable range (e.g. 10^0-10^6 CFU/mL) so as to correspond to the purpose of the alternative method. One approach would be to select different concentrations of each test micro-organism and test several replicates. For each concentration, an appropriate number of replicates is chosen to confirm linearity. The number of replicates is chosen so that the entire test can be carried out during the same working session. After checking the homogeneity of the variances of the results obtained for each concentration, the regression line is calculated. Linearity is demonstrated if the estimated slope is significant and if the test for deviation from linearity is non-significant (see general chapter *5.3*).

3-3-2-6 Range

The range of an alternative quantitative method is the interval between the upper and lower levels of micro-organisms as determined from the related studies of precision, accuracy and linearity using the specified method; it is dependent on the intended application.

3-3-2-7 Robustness

The robustness of an alternative quantitative method is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters (e.g. incubation period or incubation temperature range). Robustness is a validation parameter best suited to determination by the supplier of the method. Nevertheless, if the user modifies critical parameters, the effects on robustness must be evaluated. Robustness of an alternative quantitative method is judged by its ability to accurately enumerate the test micro-organisms after deliberate variations to the method parameters.

3-3-2-8 Suitability testing

The alternative method must be applied according to the specified procedure and with the samples to be analysed under the responsibility of the user. It must be shown that the test sample does not interfere with the system's enumeration capacity or microbial recovery. Specific points to be addressed are:

— the ability of the test to detect micro-organisms in the presence of the sample matrix;
— verifying if the sample matrix interferes with the alternative system (e.g. background signal or inhibiting chemical reactions).

Acceptance criteria for the method are defined as a function of the application and of the validation data.

3-3-2-9 Equivalence testing

Equivalence testing of 2 quantitative methods can be conducted directly on the validation parameters. This approach requires an adequate comparison experiment at low levels of inoculation (e.g. less than 5 CFU) with sufficient numbers of replicates for relevant strains of test micro-organisms. Alternatively, and in some cases additionally, equivalence testing can be carried out by the parallel testing of a predefined number of samples or for a predefined period of time. This parallel testing can be justified based on a risk assessment.

If the result of the alternative method can be expressed as the number of CFUs per weight or per volume, statistical analysis of the results shall demonstrate that the results of the alternative method enable an unequivocal decision as to whether compliance with the standards of the monographs would be achieved if the official method was used.

If the result of the alternative method cannot be expressed as the number of CFUs, equivalence testing is performed using suitable parameters, followed by statistical analysis to demonstrate that the results of the alternative method enable an unequivocal decision as to whether compliance with the standards of the monographs would be achieved if the official method was used.

3-3-3 Validation of alternative identification tests

There is a large body of evidence that different methods vary considerably in their ability to identify micro-organisms. It must be accepted that a method of identification needs to be internally consistent, but may differ from others in its identification of micro-organisms.

3-3-3-1 Accuracy

The accuracy of an alternative identification method is its ability to identify the desired micro-organism to the required taxonomic level. It must be demonstrated using well-characterised reference micro-organisms, e.g. type strains. Accuracy of the identification method is usually expressed as the number of correct identifications divided by the total number of identifications.

3-3-3-2 Specificity

The specificity of an alternative identification method is its ability to discriminate micro-organisms actually present from interfering factors that cause false identification results. Such factors include chemical substances and mixtures of micro-organisms, which cause the test to identify micro-organisms not actually present in the sample material (e.g. the presence of mixtures of DNA material from 2 micro-organisms in a sequencing test leading to the false identification of a third micro-organism).

3-3-3-3 Robustness

The robustness of an alternative identification method is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters (e.g. incubation period or incubation temperature range). Robustness is a validation parameter best suited to determination by the supplier of the method. Nevertheless, if the user modifies critical parameters, the effects on robustness have to be evaluated. Robustness of an identification method is judged by its ability to correctly identify the test micro-organisms after deliberate variations to the method parameters.

M. Reference Standards

(Ph. Eur. general texts 5.12)

This chapter is published for information.

1 INTRODUCTION

'Reference standard' is used in this chapter as a general term covering reference substances, reference preparations and reference spectra.

Reference standards are frequently necessary to achieve adequate quality control of medicinal products and their components.

Reference standards are established using suitable procedures and their continued suitability for use is monitored according to a predefined programme. Where a reference standard is needed, it is an integral part of the pharmacopoeial

monograph or the manufacturer's specification. Where a European Pharmacopoeia reference standard is referred to in a monograph or general chapter, it represents the official standard that is alone authoritative in case of doubt or dispute.

2 TERMINOLOGY

Primary standard A standard designated or widely acknowledged as having the highest metrological qualities and whose property value is accepted without reference to other standards of the same property or quantity, within a specified context. This definition does not cover international standards.

International standard A primary standard provided to enable the results of biological or immunological assay procedures to be expressed in the same way throughout the world. The value assignment is in International Units (IU) or another suitable unit. The unitage is normally assigned to a first international standard by the World Health Organization (WHO) in an arbitrary manner based on an international interlaboratory study. Activities in International Units are assigned to replacement international standards, where appropriate, by comparing them with a previous standard.

Secondary standard A standard whose property value is assigned by comparison with a primary standard of the same property or quantity.

European Pharmacopoeia reference standard A reference standard established under the aegis of and adopted by the European Pharmacopoeia Commission.

European Pharmacopoeia chemical reference substance (CRS) A substance or mixture of substances intended for use as stated in a monograph or general chapter of the European Pharmacopoeia. CRSs are in general primary standards, except for those (notably antibiotics) that are calibrated in International Units. The latter are secondary standards traceable to the international standard.

European Pharmacopoeia herbal reference standard (HRS) A herbal drug preparation (usually an extract) or a herbal drug intended for use as stated in a monograph or general chapter of the European Pharmacopoeia. Unless otherwise specified, HRSs are designated as primary reference standards for their intended use.

European Pharmacopoeia biological reference preparation (BRP) A substance or mixture of substances intended for use as stated in a monograph or general chapter of the European Pharmacopoeia. BRPs are either secondary standards calibrated in International Units or primary standards, which may be used to define a European Pharmacopoeia Unit (Ph. Eur. U.). Other assigned contents may also be used, for example, virus titre or number of bacteria.

Reference material (RM) A material sufficiently homogeneous and stable with respect to one or more specified properties, which has been established to be fit for its intended use in the measurement process.

Certified reference material (CRM) A reference material characterised by a metrologically valid procedure for one or more specified properties, accompanied by a certificate that states the value of the specified property, its associated uncertainty, and a statement of metrological traceability.

3 USE OF EUROPEAN PHARMACOPOEIA REFERENCE STANDARDS

European Pharmacopoeia reference standards are employed in the identification, purity testing and assay of articles subject to a European Pharmacopoeia monograph or general chapter. European Pharmacopoeia reference standards are shown to be suitable for their intended purpose; they are not necessarily suitable for other purposes. If a European Pharmacopoeia reference standard is to be used for any purpose other than that for which it has been established, its suitability for the new use has to be fully demonstrated and when applicable, to be described in the marketing authorisation application. Any value assigned to a reference standard is valid for the intended use and not necessarily for other uses.

A European Pharmacopoeia reference standard with an assigned content/potency for use in the assay of a substance for pharmaceutical use (see general monograph *Substances for pharmaceutical use (2034)*) may be suitable to determine the content/potency of that substance in a pharmaceutical preparation provided all of the following conditions are fulfilled:

- the chromatographic assay method described in the active substance monograph is employed;
- the applicability of the method to the particular pharmaceutical preparation (absence of interference) is verified by the user;
- any pre-treatment of the sample (e.g. extraction, filtration) is validated for the particular pharmaceutical preparation.

It is the policy of the European Pharmacopoeia to supply reference standards in adequate quantities for immediate use (i.e. the quantity needed to perform the test(s) described in the monograph or general chapter) after opening of the container. Use in other conditions is the responsibility of the analyst. If an unopened container is stored in the recommended conditions, it remains suitable for use as long as it is of the current batch. Information on current batch numbers is provided in the European Pharmacopoeia reference standards database (http://go.edqm.eu/RS). Storage of reconstituted or diluted solutions of reference standards is not recommended unless suitability has been demonstrated by the user.

Secondary standards A secondary standard is usually established to reduce the use of the primary standard and may be used for routine quality control purposes.
A secondary standard shall exhibit the same property or properties as the primary standard to which it is traceable. It shall therefore be used for the same purpose as the primary standard.

International standards are usually available in relatively limited quantities and are intended to be used for the characterisation and calibration of secondary standards; these secondary standards may then be used as working standards.

4 ESTABLISHMENT OF REFERENCE STANDARDS

4-1 PRIMARY STANDARDS

A substance or preparation to be established as a primary standard is characterised by a variety of analytical techniques chosen to demonstrate its suitability for use.

For reference standards used for the control of medicinal products and their components, relevant parts of the following test programme are usually applied.

Test programme:

- Characterisation of the substance (structural elucidation) by appropriate chemical attributes such as structural formula, empirical formula, molecular mass or composition. A number of techniques may be used including:
  - nuclear magnetic resonance spectrometry;
  - mass spectrometry;

  - infrared spectrophotometry;
  - elemental analysis.
- Determination of purity:
  - determination of the content of related substances by an appropriate separation technique and/or spectrometric method, where applicable;
  - quantitative determination of water;
  - determination of the content of residual solvents;
  - determination of loss on drying, which may in certain circumstances replace the determinations of water and residual solvents;
  - determination of inorganic impurities (e.g. sulfated ash, atomic absorption spectrometry, inductively coupled plasma spectrometry, X-ray fluorescence spectrometry); the results are usually not used to determine an assigned content, except where they would have an appreciable impact upon it;
  - determination of purity by an independent method (e.g. quantitative nuclear magnetic resonance spectrometry, differential scanning calorimetry or titration where appropriate; the results of these determinations are usually used to support and confirm the results obtained from separation techniques; they are not used in the calculation of the assigned content).

For biologicals, guidance is given in the WHO recommendations for the preparation, characterisation and establishment of international and other biological reference standards (WHO Technical Report Series).

4-2 EUROPEAN PHARMACOPOEIA CHEMICAL REFERENCE SUBSTANCES

The extent of testing and the number of laboratories involved in the establishment of a CRS depend on the use of the CRS and are tailored to ensure fitness for purpose.

Where an interlaboratory study is carried out during establishment, a protocol is provided for each participant and only valid results derived according to the protocol are used to determine an assigned content or otherwise confirm suitability.

Relevant parts of the following programme are typically applied.

4-2-1 Identification

In general, the candidate batch is shown to comply with the relevant requirements of the monograph; full structural elucidation is carried out for the first batch.

4-2-2 Related substances test

A CRS corresponding to an impurity is characterised for identity and purity. Where a CRS is used to determine the content of a given impurity, the preferred minimum content is 95.0 per cent; where this is achieved the assigned content of the CRS is not given and it is considered to be 100.0 per cent; this approximation is acceptable since there will be no appreciable effect on the determination of impurities. When this minimum content cannot be obtained, an assigned content is given to the CRS.

CRSs used to determine the content of a given impurity are normally in the same acid, base or salt form as the substance that is the subject of the corresponding monograph. Where this is not the case, unless otherwise justified, a corresponding stoichiometric conversion factor is applied.

If an impurity is not available in a sufficient quantity to establish a CRS, a number of other options exist:

- preparation of a CRS that contains a mixture of the compound(s) and the impurity or impurities;
- preparation of a CRS containing a mixture of specified impurities.

Where such a mixture is also used to determine the content of a given impurity, the content of the impurity in the CRS is determined by appropriate separation methods and a content is assigned to the reference standard.

4-2-3 Assay

4-2-3-1 Chemical assay. When a CRS is to be used for quantitative determination of a substance for pharmaceutical use (assay standard), the extent of testing is greater than when a CRS is used for other purposes. Unless the substance is of high purity, several collaborating laboratories are usually involved in testing. The results obtained are used to assign a content. It is particularly important to quantify the impurities if a selective assay is employed. In such a case, it is best to characterise the candidate substance by additional analytical procedures that are scientifically justified, including, where possible, independent methods and methods based on different principles.

For a European Pharmacopoeia chemical reference substance established for assay purposes, the assigned content is usually calculated from the values obtained from the analyses performed for the determination of impurities (organic, inorganic, water and solvents) by applying the principle of mass balance; other suitable methods may also be used. When possible, the assigned content is confirmed by comparing with the result obtained by an independent method.

If a CRS is required for a non-chromatographic assay method (e.g. colorimetry or ultraviolet spectrophotometry), the relative reactivity or relative absorbance of the impurities present in a substance must be checked to ensure that they are not markedly different from those of the substance.

Unless otherwise stated, an assigned content is given for the substance or preparation as presented in the container ('as is'), and the contents are not to be dried before use.
For assay standards prepared by lyophilisation, the content of the pure substance is indicated in milligrams or International Units per vial.

4-2-3-2 Microbiological assay. The potency is expressed in International Units or in European Pharmacopoeia Units if no international standard exists. The assigned potency together with the confidence limits are calculated from statistically valid results of an interlaboratory study, according to the usual statistical procedures (*5.3*).

4-2-3-3 Assay of components of herbal drugs and herbal drug preparations. Reference standards used in monographs on herbal drugs vary in the extent of testing depending on the type of reference standard.

An active component or marker constituent used as a CRS is usually characterised and evaluated for identity and purity; a value for content is assigned irrespective of the purity.

4-2-4 Establishment report

A report containing the results of the establishment study as well as information concerning the use of the CRS is prepared by EDQM, approved by the relevant group of experts and adopted by the European Pharmacopoeia Commission. The report for an assay standard indicates the content assigned to the substance with the rationale for this assignment. The estimated uncertainty of the assigned content is calculated, and where it is less than a predefined value, which is considered to be negligible in relation to the acceptance criteria for the assay, then the study is accepted. Otherwise, the study may be repeated, in whole or in part, or

the limits defined for the pharmaceutical substance may be widened. The uncertainty of the assigned content is usually not given as part of the information provided with the CRS, since the method performance and the uncertainty of the content assigned to the CRS are taken into account when setting the limit(s) in a monograph.

4-3 EUROPEAN PHARMACOPOEIA HERBAL REFERENCE STANDARDS

A HRS is used when the available quantity of pure constituent to be assayed is considered either insufficient or non-sustainable. HRSs may also be established for purposes other than assays, notably for use in tests for adulteration or for system suitability. A HRS is characterised by a variety of analytical techniques chosen to demonstrate its suitability for the intended use; relevant parts of the following test programme may be applied.

Test programme:

- — macroscopy;
- — microscopy;
- — thin-layer chromatography;
- — gas chromatography;
- — liquid chromatography;
- — quantitative determination of water;
- — content of residual solvents;
- — loss on drying;
- — foreign matter;
- — assay of constituents (e.g. constituents with known therapeutic activity, active markers, analytical markers) relevant to the intended use of the reference standard.

The extent of testing and the number of laboratories involved in the establishment of a HRS depend on its intended use.

For a European Pharmacopoeia herbal reference standard used for assay purposes, the assigned content is usually established by an interlaboratory study, using the assay method specified in the individual monograph in which the reference standard is intended to be used, comparing against a suitable pure sample of the constituent or constituents for which the content is to be assigned.

Establishment report

The establishment report for the HRS is prepared in the same manner as CRSs (see section 4-2-4).

4-4 EUROPEAN PHARMACOPOEIA BIOLOGICAL REFERENCE PREPARATIONS AND CHEMICAL REFERENCE SUBSTANCES FOR BIOLOGICALS

Most BRPs and some CRSs used for the testing of biological substances and preparations are established through the Biological Standardisation Programme, under the aegis of the Council of Europe and the European Commission. These reference standards are usually secondary standards calibrated against the corresponding WHO international standard. Where no international standard is available, they are primary standards with an assigned content/potency in European Pharmacopoeia Units or another suitable unit. They are established through interlaboratory studies where participating laboratories test the candidate material(s) and valid data are used to assign the official potency/content. Some of these studies are jointly organised with other organisations to establish a common material or batch of material as standard. In these cases, although the material constituting the European Pharmacopoeia reference standard may be identical to the international standard and its use may be validated through the same interlaboratory study, it is considered as a secondary standard for use as a working standard.

The study reports are endorsed by the study participants and approved by the relevant European Pharmacopoeia group of experts, where applicable, and by the Steering Committee of the Biological Standardisation Programme. The study results are then submitted to the European Pharmacopoeia Commission. Reference standards/materials established through the Biological Standardisation Programme are officially adopted by the European Pharmacopoeia Commission. The establishment reports are published in *Pharmeuropa Bio & Scientific Notes* (http://pharmeuropa.edqm.eu/PharmeuropaBioSN).

4-5 SECONDARY STANDARDS

A secondary standard should exhibit the same property or properties as the primary standard, relevant for the test(s) for which it is established. The extent of testing may not be as comprehensive as is required for the establishment of a primary standard. The secondary standard is established by comparison with the primary standard to which it is traceable. An official primary standard is used wherever possible for establishment of secondary standards.

5 MANUFACTURING, LABELLING, STORAGE AND DISTRIBUTION OF EUROPEAN PHARMACOPOEIA REFERENCE STANDARDS

5-1 MANUFACTURING

All operations are carried out according to the relevant best practices to ensure the traceability and integrity of the reference standard. The manufacturing record includes information regarding filling, labelling and storage. Reference standards are dispensed into containers under appropriate filling and closure conditions to ensure the integrity of the reference standard. The containers employed may be multi-use or single-use, but the latter is preferred to minimise the risk of decomposition, contamination or water uptake.

5-2 LABELLING

The label bears the name of the reference standard, the name and address of the supplier, the batch number and unit quantity (quantity per vial/ampoule).

An accompanying leaflet, considered as part of the labelling, is normally provided.

If used as an assay standard, the following information is also given:

- — the assigned percentage content;
- — or, the content in milligrams or millilitres of the chemical entity in the container;
- — or, the assigned potency (for biological assays or microbiological assays) in units either per milligram, per millilitre or per vial/ampoule.

For European Pharmacopoeia reference standards, no re-test or expiry date is given since the re-test programme (see section 6) monitors continued fitness for use. A batch validity statement (BVS) for each European Pharmacopoeia reference standard is available from the European Pharmacopoeia reference standards database (http://go.edqm.eu/RS).

5-3 STORAGE AND DISTRIBUTION

Reference standards are to be stored and distributed in conditions suitable to ensure optimal stability.

Most European Pharmacopoeia reference standards are stored in temperature-controlled rooms at 5 ± 3 °C. However, a number of reference standards are stored at −20 ± 5 °C and some (e.g. live virus preparations) are stored at − 80 ± 10 °C or at −196 °C to −170 °C under liquid nitrogen.

Appropriate packaging is used to minimise the risk of damage during transport, to keep the reference standard at the

appropriate temperature when necessary and to comply with the current transport regulations.

Reference standards that are stored at 5 ± 3 °C are normally transported without cooling when short-term excursions from the long-term storage temperature are not deleterious to the reference standard. Some of them may nevertheless be sent at + 5 °C, packed with cold packs in cases where an increase in temperature is detrimental to their stability. Reference standards stored at − 20 °C are packed with cold packs or on dry ice (solid carbon dioxide) and dispatched by express courier or air freight. Reference standards stored at − 80 °C or stored under liquid nitrogen are packed on solid carbon dioxide.

Delivery conditions, dispatch and storage temperatures are available in the Reference Standards Catalogue, the Terms of Supply and the European Pharmacopoeia reference standards database (http://go.edqm.eu/RS).

6 RE-TEST PROGRAMME OF EUROPEAN PHARMACOPOEIA STANDARDS

A system is established and implemented to ensure the continued fitness-for-use of the European Pharmacopoeia reference standards. Normally, a re-test programme is applied, taking account of the known physico-chemical properties and stability data for the reference standard. Reference standards are periodically tested for stability during storage. A monitoring programme is applied that is designed to detect at an early stage any sign of degradation using appropriate analytical techniques. The methods employed are typically chosen from amongst those performed during establishment of the reference standard so that baseline data is available.

The periodicity and extent of re-testing reference standards depends on a number of factors including:
- stability;
- container and closure system;
- storage conditions;
- hygroscopicity;
- physical form;
- intended use;
- presentation (single use/multiple use).

The re-test period may be lengthened with the support of sufficient data. The maximum permitted variation from the assigned content should be pre-defined, and if exceeded, the batch should be re-established or replaced.

N. Gene Transfer Medicinal Products for Human Use

(Ph. Eur. general texts 5.14)

This general chapter is published for information.

This general chapter contains a series of texts on gene transfer medicinal products for human use. The texts provide a framework of requirements applicable to the production and control of these products. For a specific medicinal product, application of these requirements and the need for any further texts is decided by the competent authority. The texts are designed to be applicable to approved products; the need for application of part or all of the texts to products used during the different phases of clinical trials is decided by the competent authority. The provisions of the chapter do not exclude the use of alternative production and control methods that are acceptable to the competent authority.

Further detailed recommendations on gene transfer medicinal products for human use are provided by the Note for Guidance on the Quality, Preclinical and Clinical Aspects of Gene Transfer Medicinal Products (CPMP/BWP/3088/99) and the Guideline on Development and Manufacture of Lentiviral Vectors (CHMP/BWP/2458/03) of the Committee for Medicinal Products for Human Use (including any subsequent revisions of these documents).

DEFINITION

For the purposes of this general chapter, gene transfer medicinal product (GTMP) shall mean a product obtained through a set of manufacturing processes aimed at the transfer, to be performed either *in vivo* or *ex vivo*, of a prophylactic, diagnostic or therapeutic gene (i.e. a piece of nucleic acid) to human/animal cells, and its subsequent expression *in vivo*. The gene transfer involves an expression system known as a vector, which can be of viral as well as non-viral origin. The vector can also be included in a human or animal cell.

Recombinant vectors, such as viral vectors and plasmids Recombinant vectors are either injected directly into the patient's body (*in vivo* gene transfer) or transferred into host cells before administration of these genetically modified cells to the patient (*ex vivo* gene transfer). Viral vectors are derived from various viruses (for example, adenoviruses, poxviruses, retroviruses, lentiviruses, adeno-associated-viruses, herpesviruses). These vectors can be replicative, non-replicative or conditionally replicative. Plasmid vectors include nucleic acids in a simple formulation (for example, naked DNA) or complexed to various molecules (synthetic vectors such as lipids or polymers). Genetic material transferred by GTMPs consists of nucleotide sequences, which may notably encode gene products, antisense transcripts or ribozymes. Chemically synthesised oligonucleotides are not within the scope of this general chapter. After transfer, the genetic material may remain either cytoplasmic or episomal, or may be integrated into the host cell genome, depending on the integrating or non-integrating status of the vector.

Genetically modified cells Genetically modified eukaryotic or bacterial cells are modified by vectors to express a product of interest.

PRODUCTION

Substances used in production

The raw materials used during the manufacturing process, including viral seed lot and cell bank establishment, where applicable, are qualified. Unless otherwise justified, all substances used are produced within a recognised quality management system using suitable production facilities. Suitable specifications are established to control notably their identity, potency (where applicable), purity and safety in terms of microbiological quality and bacterial endotoxin contamination. The quality of water used complies with the relevant corresponding monographs (*Purified water (0008)*, *Water for injections (0169)*). Where bovine serum is used, it complies with the monograph *Bovine serum (2262)*. The use of antibiotics is avoided wherever possible during production.

Viral safety

The requirements of chapter *5.1.7* apply.

Transmissible spongiform encephalopathies (*5.2.8*)

A risk assessment of the product with respect to transmissible spongiform encephalopathies is carried out and suitable measures are taken to minimise such risk.

RECOMBINANT VECTORS

PRODUCTION

GENERAL PROVISIONS

For viral vectors, production is based on a cell bank system and a virus seed-lot system, wherever possible.

For plasmid vectors, production is based on a bacterial cell bank system.

The production method shall have been shown to yield a vector of consistent quality. Unless otherwise justified and authorised, the vector in the final product shall have undergone no more passages or subcultures from the master seed lot than were used to prepare the vector shown in clinical trials to be satisfactory with respect to safety and efficacy.

SUBSTRATE FOR VECTOR PROPAGATION

The substrates used comply with relevant requirements of the European Pharmacopoeia (*5.2.2*, *5.2.3*, and the section Bacterial cells used for the manufacture of plasmid vectors for human use).

CHARACTERISATION OF THE VECTOR

Historical records of vector construction are documented, including the origin of the vector and its subsequent manipulation, notably deleted or modified regions.

The vector is characterised using suitable and validated methods.

The genetic stability of the vector at or beyond the maximum passage level or the maximum number of cell doublings of the cell line used for production is assessed by suitable methods.

PROPAGATION AND HARVEST

All processing of the cell banks and subsequent cell cultures is done in an area where no other cells or vectors are handled at the same time. Any material of human or animal origin used in the preparation of cell suspensions and culture media is qualified. The purity of the harvest is verified by suitable tests as defined in the corresponding specific sections.

PURIFIED HARVEST

The bulk of active substance is defined as a lot of purified recombinant vectors (viral vectors, or naked or complexed plasmids).

FINAL LOT

Unless otherwise justified and authorised, formulation and distribution of the final bulk is carried out under aseptic conditions using sterile containers (*3.2*).

The stability of the final lot is assessed using stability protocols including the duration, storage conditions, number of lots to be tested, test schedule and assays to be performed.

ASSAYS AND TESTS

The GTMPs comply with assays and tests described in the corresponding specific sections.

GENETICALLY MODIFIED CELLS

For cells to be modified with a recombinant vector, the data related to the recombinant vector are documented above, under Recombinant vectors.

PRODUCTION

CELL SUBSTRATE

For xenogeneic cell lines, including bacterial cells, a cell bank system comprising a master cell bank and working cell banks is established.

For autologous and allogeneic cells, a cell banking system comprising a master cell bank and working cell banks is established wherever possible.

TRANSFECTION / TRANSDUCTION

Cells are transfected or transduced using a recombinant vector (plasmid or viral vector) qualified as described under Recombinant vectors; the process is validated. They are handled under aseptic conditions in an area where no other cells or vectors are handled at the same time. All reagents used during cell manipulation steps are fully qualified. Antibiotics are avoided unless otherwise justified and authorised. Transfection or transduction is carried out under aseptic conditions.

FINAL LOT

In the case of frozen storage, the viability of genetically modified cells is assessed before freezing and after thawing.

If the cells are not used within a short period, stability is determined by verifying cell viability and expression of the genetic insert.

In the case of genetically modified cells encapsulated before implantation in man, any encapsulating component used is considered as part of the final product, and is therefore quality-controlled and fully characterised (for example, physical integrity, selective permeability, sterility).

ASSAYS AND TESTS

Controls of xenogeneic, allogeneic or autologous cells include the following:

— identity, counting and viability of cells;
— overall integrity, functionality, copies per cell, transfer and expression efficiency of the genetic insert;
— microbiological controls (*2.6.1* or *2.6.27*), endotoxin content, mycoplasma contamination (*2.6.7*), adventitious virus contamination and, where applicable, replicative vector generation.

The competent authority may approve a reduced testing programme where necessary because of limited availability of cells. Where necessary because of time constraints, the product may be released for use before the completion of certain tests.

PLASMID VECTORS FOR HUMAN USE

DEFINITION

Plasmid vectors for human use are double-stranded circular forms of bacterial DNA that carry a gene of interest or a nucleotide sequence encoding antisense sequences or ribozymes and its expression cassette; they are amplified in bacteria extrachromosomally. They are used to transfer genetic material into human somatic cells *in vivo* or to genetically modify autologous, allogeneic, xenogeneic or bacterial cells before administration to humans. Plasmid vectors may be presented as naked DNA or may be formulated with synthetic delivery systems such as lipids (lipoplexes), polymers (polyplexes) and/or peptide ligands that facilitate transfer across the cell membrane and delivery to the cell, or that target delivery via specific receptors.

Plasmids formulated with synthetic delivery systems are not within the scope of this section.

PRODUCTION

PLASMID CONSTRUCTION

A typical plasmid vector is composed of:

— the plasmid vector backbone that contains multiple restriction endonuclease recognition sites for insertion of the genetic insert and the bacterial elements necessary for

plasmid production, such as selectable genetic markers for the identification of cells that carry the recombinant vector;
- the required regulatory genetic elements to facilitate expression of the genetic insert;
- the genetic insert;
- a polyadenylation signal.

A complete description of the plasmid DNA, including its nucleotide sequence, is established with the identification, source, means of isolation and nucleotide sequence of the genetic insert. The source and function of component parts of the plasmid, such as the origin of replication, viral and eukaryotic promoters and genes encoding selection markers, are documented.

GENERAL PROVISIONS

Cell banks
Production of plasmid vectors is based on a bacterial cell-bank system with generation and characterisation of a master cell bank (MCB), working cell banks (WCBs) and end-of-production cells (EOPCs), which comply with the section Bacterial cells used for the manufacture of plasmid vectors for human use. The raw materials used during the manufacturing process, including cell bank establishment, are qualified.

Selection techniques
Unless otherwise justified and authorised, antibiotic-resistance genes used as selectable genetic markers, particularly for clinically useful antibiotics, are not included in the vector construct. Other selection techniques for the recombinant plasmid are preferred.

Reference standards
A suitable batch of the formulated plasmid, preferably one that has been clinically evaluated, is fully characterised and retained for use as a reference standard as necessary in routine control tests.

PROPAGATION AND HARVEST
Plasmid DNA is transferred to host strain bacterial cells and a single clone of transformed bacteria is expanded to create the MCB. The WCB is then derived from the MCB. The EOPCs are obtained from the WCB by fermentation in production conditions.

Plasmid DNA is isolated from harvested cells using an extraction step and is purified to obtain the bulk product.

Unless otherwise justified and authorised, caesium chloride-ethidium bromide density gradients are not used for production.

PURIFIED PLASMID
The production process is optimised to remove impurities consistently while retaining product activity. The requirement to test for a particular impurity depends on the following:
- the demonstrated capability of the manufacture and purification processes to remove or inactivate the impurity through process validation, using specific quantification methods;
- the potential toxicity associated with the impurity;
- the potential decrease of the efficacy of the genetic insert product associated with the impurity.

If selective resistance to specific antibiotics has been used for selection, data from validation studies of purification procedures are required to demonstrate the clearance capability for residual antibiotics.

Relevant in-process controls are performed to ensure that the process is continuously under control, for example, amount and form of plasmid after the extraction steps and amount of endotoxins after the extraction steps.

Only a batch of purified plasmid that complies with the following requirements may be used.

Identity and integrity of the purified plasmid
Identity and integrity of the purified plasmid are established by suitable methods such as sequencing or nucleic acid amplification techniques (NAT) (*2.6.21*); restriction enzyme analysis may be used where it is sufficient to detect potential critical modifications in the plasmid and confirm the plasmid identity.

Plasmid DNA
The following indications are given as examples.

DNA concentrations greater than 500 ng/mL may be determined using absorbance measurement at 260 nm. A 50 µg/mL double-stranded DNA solution has an absorbance of 1 (specific absorbance 200).

DNA concentrations less than 500 ng/mL are determined following incubation with fluorescent dyes that bind specifically to double-stranded DNA, using a reference standard of DNA to establish a calibration curve.

Liquid chromatography may also be used to determine the concentration of plasmid DNA using a reference standard. In some cases, capillary electrophoresis is also acceptable.

DNA forms
Plasmid DNA is characterised in terms of the proportions of supercoiled, multimeric, relaxed monomer and linear forms, using suitable analytical methods, examples of which are given below. For quantification of supercoiled forms, anion-exchange high performance liquid chromatography (HPLC) or capillary electrophoresis may be used. Capillary electrophoresis is also suitable for the quantification of other forms.

Residual host-cell DNA
The content of residual host-cell DNA is determined using a suitable method, unless the process has been validated to demonstrate suitable clearance. Quantitative PCR is recommended for its sensitivity and specificity, but other suitable techniques may also be used.

Residual RNA
The content of residual RNA is determined, unless the process has been validated to demonstrate suitable clearance. Reverse-phase HPLC (RP-HPLC) may be used, or quantitative reverse-transcriptase polymerase chain reaction (RT-PCR) (*2.6.21*) when a lower limit of detection is required.

Residual host-cell protein
The concentration of residual host-cell protein is determined using standard protein assays (*2.5.33*), SDS-PAGE followed by silver staining, or specific immuno-assays such as western blot or ELISA, unless the process has been validated to demonstrate suitable clearance.

Microbiological control
Depending on the preparation concerned, it complies with the test for sterility (*2.6.1*) or the bioburden is determined (*2.6.12*).

Bacterial endotoxins (*2.6.14*)
Less than the limit approved for the particular preparation.

FINAL BULK
Several purified harvests may be pooled during preparation of the final bulk. A stabiliser and other excipients may be added. The formulated product is filtered through a bacteria-retentive filter.

Only a final bulk that complies with the following requirement may be used in the preparation of the final lot.

Sterility (*2.6.1*)
It complies with the test for sterility.

FINAL LOT
Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use.

IDENTIFICATION
The plasmid vector is identified by restriction enzyme analysis or by sequencing. The test for biological activity also serves to identify the product.

TESTS
Tests carried out on the final lot include the following.

Appearance

pH (*2.2.3*)
Within the limits approved for the particular preparation.

Extractable volume (*2.9.17*)
It complies with the test for extractable volume.

Residual moisture (*2.5.12*)
Within the limits approved for the particular freeze-dried preparation.

DNA forms
The percentage of the specific monomeric supercoiled form is determined as described for the purified plasmid.

Sterility (*2.6.1*)
It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*)
Less than the limit approved for the particular preparation.

ASSAY

Plasmid DNA
Not less than the quantity stated on the label, determined, for example, by 1 of the following methods.

DNA concentrations greater than 500 ng/mL may be determined using absorbance measurement at 260 nm. A 50 µg/mL double-stranded DNA solution has an absorbance of 1 (specific absorbance 200).

DNA concentrations less than 500 ng/mL are determined following incubation with fluorescent dyes that bind specifically to double-stranded DNA, using a reference standard of DNA to establish a calibration curve.

Liquid chromatography may also be used to determine the concentration of plasmid DNA using a reference standard. In some cases, capillary electrophoresis is also acceptable.

Biological activity
Wherever possible, biological activity is assessed through *in vitro* or *in vivo* bioassays. A well-defined, representative reference standard is required as a positive control for the assay. Bioassays employed to assay plasmid vectors generally involve transfection of a relevant cell line *in vitro*, followed by some functional measure of the expressed genetic insert. Such functional assays provide information about the activity of the product encoded by the genetic insert instead of the expression level of the genetic insert itself.

It may be necessary to supplement the bioassay with western-blot and ELISA assays to assess the integrity and quantity of the expressed product.

LABELLING
The label states:
— the plasmid DNA concentration;
— the recommended human dose;
— for freeze-dried preparations:
  — the name and volume of the liquid to be added;
  — the time within which the product is to be used after reconstitution.

BACTERIAL CELLS USED FOR THE MANUFACTURE OF PLASMID VECTORS FOR HUMAN USE

Production of plasmid vectors for human use is based on the use of a bacterial cell-bank system with generation and characterisation of a master cell bank (MCB), working cell banks (WCBs) and end-of-production cells (EOPCs).
A bacterial cell bank for the manufacture of plasmid vectors is a collection of vials containing bacterial cells stored under defined conditions, with uniform composition, and obtained from pooled cells derived from a single clone of a transformed host strain. The MCB has a known, documented history; it is preferably derived from a qualified repository source. The WCB is produced by expanding one or more vials of the MCB. Methods and reagents used to produce the bank and storage conditions are documented.

MCBs and WCBs are qualified by testing an aliquot of the banked material or testing a subculture of the cell bank.

The following table indicates the tests required at each stage of production.

Assay	Host strain	MCB	WCB	EOPCs*
Identity and purity				
Viability	+	+	+	+
Bacterial strain characterisation	+	+	–	+
Genotyping / phenotyping	+	+	–	+
Presence of the plasmid				
— Sequence of the DNA plasmid	–	+	–	+
— Copy number	–	+	+	+
— Restriction map	–	+	+	+
— Percentage of cells retaining the plasmid	–	+	+	+
Adventitious agents				
Purity by plating	+	+	+	+
Presence of bacteriophage	+	+	–	+

* EOPCs are cells with a passage number at least equivalent to that used for production. The analysis has to be done once to validate each new WCB, except for purity, which has to be tested for each fermentation.

IDENTITY AND PURITY TESTING

Viability
The number of viable cells is determined by plating a diluted aliquot of bacterial cells on an appropriate medium and counting individual colonies.

Biochemical and physiological bacterial strain characterisation
Depending on the bacterial strain used for production, relevant biochemical and physiological characterisation is performed to confirm cell identity at the species level.

Genotyping / phenotyping
The genotype of bacterial cells is verified by determination of the suitable specific phenotypic markers or by appropriate genetic analysis.

Presence of the plasmid
Sequencing The whole nucleotide sequence of the plasmid is verified.

Copy number The plasmid DNA is isolated and purified from a known number of bacteria and the copy number

determined by a suitable method such as quantitative PCR (*2.6.21*).

Restriction map Restriction endonuclease digestion is performed with sufficient resolution to verify that the structure of the plasmid is unaltered in bacterial cells.

Percentage of cells retaining the plasmid Bacterial elements present in the plasmid, such as selectable genetic markers, are used to define the percentage of bacteria retaining the plasmid.

ADVENTITIOUS AGENTS AND ENDOGENOUS VIRUSES

Purity by plating

Bacterial cells are streaked out onto suitable media and incubated in the required conditions in order to detect potential bacterial contaminants. In order to test for inhibition of the growth of contaminating organisms, additional tests in the presence of a definite amount of relevant positive control bacteria are carried out. A suitable number of colonies is examined; no contamination is detected.

Presence of bacteriophage

Bacterial cells are plated and incubated in a medium allowing proliferation of bacteriophages, to test for bacteriophage presence. The test is validated by the use of a reference bacteriophage strain and permissive cells as positive controls. A suitable number of colonies is examined; no contamination is detected.

ADENOVIRUS VECTORS FOR HUMAN USE

DEFINITION

Adenovirus vectors for human use are freeze-dried or liquid preparations of recombinant adenoviruses, genetically modified to transfer genetic material to human somatic cells *in vivo* or *ex vivo*.

PRODUCTION

VECTOR CONSTRUCTION

There are different approaches for the design and construction of an adenovirus vector. The purpose of clinical use determines which approach is optimal. A method is chosen that minimises the risk of generating replication-competent adenovirus vectors or that effectively eliminates helper viruses that might be used during production.

VECTOR PRODUCTION

The production method shall have been shown to yield a vector of consistent quality. Unless otherwise justified and authorised, the vector in the final product shall have undergone no more passages from the master seed lot than were used to prepare the vector shown in clinical trials to be satisfactory with respect to safety and efficacy.

The genetic and phenotypic stability of the vector at or beyond the maximum passage level used for production is assessed by suitable methods.

SUBSTRATE FOR VECTOR PROPAGATION

The vector is propagated in continuous cell lines (*5.2.3*) based on a cell bank system. The occurrence of replication-competent adenoviruses may be significant when large regions of homology exist between the viral genome and the genome of the complementation cells. This occurrence may be minimised by minimising the homology between both genomes. The use of cells with no sequence homology with the vector is recommended for production.

VECTOR SEED LOT

Production of the vector is based on a seed-lot system.

The strain of adenovirus used is identified by historical records that include information on its origin and its subsequent manipulation, notably deleted or modified regions. A detailed description of the genetic insert(s) and the flanking control regions is established, including the nucleotide sequence. The method by which the genetic insert is introduced into the vector is documented.

Only a seed lot that complies with the following requirements may be used for vector production.

Identification

The vector is identified in the master seed lot and each working seed lot by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Genetic and phenotypic characterisation

The following tests are carried out.

- The entire genome of the vector is sequenced at a passage level comparable to a production batch and the analytically determined sequence is compared to the theoretical sequence based on vector construction and available databases.
- Restriction enzyme analysis is performed on the vector DNA of the master seed lot, each working seed lot and a production batch. The viral DNA is extracted, purified and digested with sufficient resolution. The digested fragments are separated by gel electrophoresis or capillary electrophoresis and the observed restriction pattern is compared to the theoretical restriction pattern based on vector construction.
- A suitable number of isolated sub-clones are tested for expression of the genetic insert product(s) and biological activity at a passage level comparable to a production batch. Sub-clones giving lower levels of expression or biological activity need further characterisation.

Vector concentration

The titre of infectious vector or the concentration of vector particles in the master seed lot and each working seed lot are determined.

Extraneous agents (*2.6.16*)

The master seed lot and each working seed lot comply with the tests for extraneous agents.

Replication-competent adenoviruses

Replication-competent adenoviruses are generated by homologous recombination between the recombinant viral DNA and the adenovirus sequences integrated into the genome of the complementation cells.

Detection of replication-competent adenoviruses is performed by a suitable method approved by the competent authority. It is generally performed by an infectivity assay on sensitive detector cell lines, which are not able to complement for the genes deleted from the vector. Other indicators of viral replication may be used as appropriate.

When replication-competent adenoviruses are not supposed to be present in the test sample, considering vector construction and cell lines used, at least 2, but preferably 3 or 4 successive passages are performed on the detector cell line, where applicable. Detection of a cytopathic effect at the end of the passages reveals the presence of replication-competent adenoviruses in the preparation. Positive controls are included in each assay to monitor its sensitivity.

When replication-competent adenoviruses are expected to be present in the test sample, plaque-assays or limit dilution assays on a detector cell line may be performed.

PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done in an area with a suitable containment level where no other cells or vectors are handled at the same time.

Any material of human or animal origin used in the preparation of cell suspensions and culture media is qualified.

The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration, but it is preferable to have a substrate free from antibiotics during production. Unless otherwise justified and authorised, at no stage during production is penicillin or streptomycin used. A portion of the production cell cultures is set aside as uninfected cell cultures (control cells).

Each single harvest that complies with the following requirements may be used in the preparation of the purified harvest.

Identification

The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Vector concentration

The titre of infectious vector and the concentration of vector particles in single harvests are determined.

Extraneous agents (*2.6.16*)

The single harvest complies with the tests for extraneous agents.

Control cells

Control cells comply with a test for identification (*5.2.3*) and a test for extraneous agents (*2.6.16*).

PURIFIED HARVEST

Several single harvests may be pooled before the purification process. The purification process is validated to demonstrate the satisfactory removal of impurities.

Purified harvests that comply with the following requirements may be used in the preparation of the final bulk.

Identification

The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Genomic integrity

Genomic integrity of the vector is verified by suitable methods such as restriction enzyme analysis.

Vector concentration

The titre of infectious vector and the concentration of vector particles in purified harvests are determined.

Residual host-cell protein

The concentration of residual host-cell protein is determined by a suitable immunochemical method (*2.7.1*), unless the process has been validated to demonstrate suitable clearance.

Residual host-cell DNA

The content of residual host-cell DNA is determined using a suitable method, unless the process has been validated to demonstrate suitable clearance. Quantitative polymerase chain reaction (PCR) is recommended for its sensitivity and specificity, but other suitable techniques may also be used.

Residual reagents

Where reagents are used during the production process, tests for these substances are carried out on the purified harvest, unless the process has been validated to demonstrate suitable clearance.

Residual antibiotics

Where antibiotics are used during the production process, their residual concentration is determined by a microbiological assay (adapted from general method *2.7.2*) or by other suitable methods (for example, liquid chromatography), unless the process has been validated to demonstrate suitable clearance.

FINAL BULK

Several purified harvests may be pooled during preparation of the final bulk. A stabiliser and other excipients may be added. The formulated product is filtered through a bacteria-retentive filter.

Only a final bulk that complies with the following requirement may be used in the preparation of the final lot.

Sterility (*2.6.1*)

It complies with the test for sterility.

FINAL LOT

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for bovine serum albumin (when bovine serum is used to manufacture the vector) and replication-competent adenoviruses have been carried out with satisfactory results on the final bulk, they may be omitted on the final lot.

IDENTIFICATION

The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

TESTS

Osmolality (*2.2.35*)

Within the limits approved for the particular preparation.

pH (*2.2.3*)

Within the limits approved for the particular preparation.

Extractable volume (*2.9.17*)

It complies with the test for extractable volume.

Residual moisture (*2.5.12*)

Within the limits approved for the particular freeze-dried preparation.

Bovine serum albumin

Not more than the limit approved for the particular preparation, determined by a suitable immunochemical method (*2.7.1*), where bovine serum has been used during production.

Replication-competent adenovirus concentration

Within the limits approved for the particular preparation.

Vector aggregates

Vector aggregates are determined by suitable methods (for example, light scattering).

Sterility (*2.6.1*)

It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*)

Less than the limit approved for the particular preparation.

Thermal stability

Maintain samples of the vector final lot at a temperature and for a length of time that are adapted and authorised for the particular preparation. Determine the total infectious vector concentration after heating, as described below under Assay. Determine in parallel the vector concentration of a non-heated sample. The estimation of the difference between the total vector concentration without heating and after heating is within the limits approved for the particular preparation.

ASSAY

Vector particle concentration

Physical titration is performed by a suitable technique (for example, liquid chromatography, absorbance measurement or

NAT (*2.6.21*)). Use an appropriate vector reference standard to validate each assay.

The vector particle concentration of the preparation to be examined is not less than the concentration stated on the label.

Infectious vector titre

Titrate the preparation to be examined by inoculation into cell cultures. Titrate an appropriate vector reference standard to validate each assay.

The assay is invalid if:

— the confidence interval ($P = 0.95$) of the logarithm of the vector concentration is greater than a value authorised by the competent authority;
— the infectious vector titre of the reference standard is outside limit values defined by a control chart.

Ratio of vector particle concentration to infectious vector titre

Within the limits approved for the particular preparation.

Expression of the genetic insert product

The expression of the genetic insert product(s) is determined wherever possible, following inoculation of cell cultures with the particular preparation at a predetermined multiplicity of infection, by suitable immunochemical (*2.7.1*) or biochemical assays or by flow cytometry (*2.7.24*).

Biological activity

Unless otherwise justified and authorised, biological activity is determined by a suitable *in vitro* or *in vivo* test.

LABELLING

The label states:

— the content of active substance;
— the recommended human dose, expressed in vector particle concentration;
— for freeze-dried preparations:
  — the name or composition and the volume of the reconstituting liquid to be added;
  — the time within which the product is to be used after reconstitution.

POXVIRUS VECTORS FOR HUMAN USE

DEFINITION

Poxvirus vectors for human use are freeze-dried or liquid preparations of recombinant poxviruses, genetically modified to transfer genetic material to human somatic cells *in vivo* or *ex vivo*.

PRODUCTION

VECTOR CONSTRUCTION

The general design of a poxvirus vector is currently as follows: the genetic insert is inserted downstream of a poxvirus promoter. This expression cassette is inserted into the poxvirus genome in such a manner that it interrupts a viral gene non-essential for replication or is positioned between 2 virus open reading frames.

In most strategies used so far for the construction of the vector, the expression cassette is first inserted within the target site of a virus DNA fragment cloned into a bacterial plasmid. The plasmid is then introduced into host cells, cultured *in vitro*, which are simultaneously infected with the parental poxvirus. DNA recombination occurs within the infected cells, between homologous sequences in the viral genome and viral sequences in the plasmid so as to transfer the genetic insert into the targeted site of the viral genome. The correct targeting of the inserted DNA is checked by restriction-enzyme mapping, NAT (*2.6.21*) and sequencing.

Successive plaque-cloning steps are performed to purify the recombinant poxvirus from the mixture of parental and recombinant poxviruses. A variety of methods (for example, foreign marker genes, DNA hybridisation, immunological detection, phenotypic changes in the virus) are employed to facilitate recognition and/or selection of the recombinant poxvirus from the background of parental virus. Where foreign marker genes have been transiently employed, they are removed by appropriate methods from the final recombinant poxvirus.

An alternative strategy for creating poxvirus vectors begins with the *in vitro* construction of a full-length virus genome harbouring the expression cassette within a chosen target site. This recombinant genome is then introduced into host cells simultaneously infected with a helper poxvirus that is unable to multiply. The helper virus may be a poxvirus of the same species whose ability to multiply has been inactivated, or another poxvirus species that does not multiply in the host cells.

The construction of non-replicative poxvirus vectors relies on specific host cell lines or primary cells that are naturally permissive, or on host cell lines that have been modified to express an essential poxvirus gene. These cells fulfill the general requirements for the production of medicinal products (*5.2.3*) and do not allow the generation of replicative vectors.

VECTOR PRODUCTION

The production method shall have been shown to yield a vector of consistent quality. Unless otherwise justified and authorised, the vector in the final product shall have undergone no more passages from the master seed lot than were used to prepare the vector shown in clinical trials to be satisfactory with respect to safety and efficacy.

The genetic and phenotypic stability of the vector at or beyond the maximum passage level used for production is assessed by suitable methods.

SUBSTRATE FOR VECTOR PROPAGATION

The vector is propagated under aseptic conditions in human diploid cells (*5.2.3*), in continuous cell lines (*5.2.3*) or in cultures of chick-embryo cells derived from a chicken flock free from specified pathogens (*5.2.2*). When the vector is propagated in a continuous cell line or in human diploid cells, a cell-bank system is established.

VECTOR SEED LOT

Production of the vector is based on a seed-lot system.

The strain of poxvirus used is identified by historical records that include information on its origin and its subsequent manipulation, notably deleted or modified regions. A detailed description of the genetic insert(s) and the flanking control regions is established, including the nucleotide sequence. The method by which the genetic insert is introduced into the vector is documented.

Only a seed lot that complies with the following requirements may be used for vector production.

Identification

The vector is identified in the master seed lot and each working seed lot by immunochemical methods (*2.7.1*) or NAT (*2.6.21*).

Genetic and phenotypic characterisation

The following tests are carried out.

— The entire genome of the vector is sequenced at a passage level comparable to a production batch and the analytically determined sequence is compared to the

theoretical sequence based on vector construction and available databases.
- Restriction enzyme analysis is performed on the vector DNA of the master seed lot, each working seed lot and a production batch. The viral DNA is extracted, purified and digested with sufficient resolution. The digested fragments are separated by gel electrophoresis or capillary electrophoresis and the observed restriction pattern is compared to the theoretical restriction pattern based on vector construction.
- A suitable number of isolated sub-clones are tested for expression of the genetic insert product(s) and biological activity at a passage level comparable to a production batch. Sub-clones giving lower levels of expression or biological activity need further characterisation.
- The host range is verified by determining the replication properties of the vector and comparing them with that of the parental virus, at a passage level comparable to a production batch.

Infectious vector titre
The titre of infectious vector in the master seed lot and each working seed lot is determined.

Extraneous agents (*2.6.16*)
The master seed lot and each working seed lot comply with the tests for extraneous agents, except where cytopathic strains cannot be neutralised and the vector causes interference. Where a test cannot be performed, carry out a suitable validated alternative.

PROPAGATION AND HARVEST
All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area with a suitable containment level where no other cells or vectors are handled at the same time. Any material of human or animal origin used in the preparation of cell suspensions and culture media is qualified. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration, but it is preferable to have a substrate free from antibiotics during production. Unless otherwise justified and authorised, at no stage during production is penicillin or streptomycin used. A portion of the production cell culture is set aside as uninfected cell cultures (control cells).

Each single harvest that complies with the following requirements may be used in the preparation of the purified harvest.

Identification
The vector is identified by immunochemical methods (*2.7.1*) or NAT (*2.6.21*).

Infectious vector titre
The titre of infectious vector in single harvests is determined.

Extraneous agents (*2.6.16*)
The single harvest complies with the tests for extraneous agents, except where cytopathic strains cannot be neutralised and the vector causes interference. Where a test cannot be performed, carry out a suitable validated alternative.

Control cells
If human diploid cells or a continuous cell line are used for production, the control cells comply with a test for identification (*5.2.3*). They comply with the tests for extraneous agents (*2.6.16*).

PURIFIED HARVEST
Processing is carried out under aseptic conditions. Several single harvests may be pooled before the purification process. The harvest is first clarified to remove cells and then, where applicable, purified by validated methods.

Purified harvests that comply with the following requirements may be used in the preparation of the final bulk.

Identification
The vector is identified by immunochemical methods (*2.7.1*) or NAT (*2.6.21*).

Genomic integrity
Genomic integrity of the vector is verified by suitable methods such as restriction enzyme analysis.

Infectious vector titre
The titre of infectious vector in purified harvests is determined.

Ratio of infectious vector titre to total protein concentration
The total protein concentration is determined by a suitable method (*2.5.33*). The ratio between infectious vector titre and total protein concentration is calculated.

Residual host-cell protein
The concentration of residual host-cell protein is determined by a suitable immunochemical method (*2.7.1*), unless the process has been validated to demonstrate suitable clearance.

Residual host-cell DNA
The content of residual host-cell DNA is determined using a suitable method, unless the process has been validated to demonstrate suitable clearance. Quantitative PCR is recommended for its sensitivity and specificity, but other suitable techniques may also be used.

Residual reagents
Where reagents are used during the production process, tests for these substances are carried out on the purified harvest, unless the process has been validated to demonstrate suitable clearance.

Residual antibiotics
Where antibiotics are used during the production process, their residual concentration is determined by a microbiological assay (adapted from general method *2.7.2*) or by other suitable methods (for example, liquid chromatography), unless the process has been validated to demonstrate suitable clearance.

FINAL BULK
Several purified harvests may be pooled during preparation of the final bulk. A stabiliser and other excipients may be added.

Only a final bulk that complies with the following requirement may be used in the preparation of the final lot.

Sterility (*2.6.1*)
It complies with the test for sterility.

FINAL LOT
Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the test for bovine serum albumin (when bovine serum is used to manufacture the vector) has been carried out with satisfactory results on the final bulk, it may be omitted on the final lot.

IDENTIFICATION
The vector is identified by immunochemical methods (*2.7.1*) or NAT (*2.6.21*).

TESTS
Osmolality (*2.2.35*)
Within the limits approved for the particular preparation.

pH (*2.2.3*)
Within the limits approved for the particular preparation.

Extractable volume (*2.9.17*)
It complies with the test for extractable volume.

Residual moisture (*2.5.12*)
Within the limits approved for the particular freeze-dried preparation.

Bovine serum albumin
Not more than the limit approved for the particular preparation, determined by a suitable immunochemical method (*2.7.1*), where bovine serum has been used during production.

Sterility (*2.6.1*)
It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*)
Less than the limit approved for the particular preparation.

Thermal stability
Maintain samples of the vector final lot at a temperature and for a length of time that are adapted and authorised for the particular preparation. Determine the total infectious vector concentration after heating, as described below under Assay. Determine in parallel the vector concentration of a non-heated sample. The estimation of the difference between the total vector concentration without heating and after heating is within the limits approved for the particular preparation.

ASSAY

Infectious vector titre
Titrate at least 3 vials of the preparation to be examined by inoculation into cell cultures. Titrate a vial of an appropriate vector reference standard to validate each assay.

The vector titre of the preparation to be examined is not less than the minimum titre stated on the label.

The assay is invalid if:
- the confidence interval ($P = 0.95$) of the logarithm of the vector concentration is greater than a value authorised by the competent authority;
- the infectious vector titre of the reference standard is outside limit values defined by a control chart.

Expression of the genetic insert product
The expression of the genetic insert product(s) is determined, wherever possible, following inoculation of cell cultures with the particular preparation at a predetermined multiplicity of infection, by suitable immunochemical (*2.7.1*) or biochemical assays or by flow cytometry (*2.7.24*).

Biological activity
Unless otherwise justifed and authorised, biological activity is determined by a suitable *in vitro* or *in vivo* test.

LABELLING

The label states:
- the minimum vector titre per human dose;
- the recommended human dose;
- for freeze-dried preparations:
  - the name or composition and the volume of the reconstituting liquid to be added;
  - the time within which the product is to be used after reconstitution.

RETROVIRIDAE-DERIVED VECTORS FOR HUMAN USE

DEFINITION

Retroviridae-derived vectors for human use are liquid or freeze-dried preparations of recombinant retroviruses, lentiviruses or spumaviruses, genetically modified to render them replication-incompetent, which are used to transfer genetic material to human somatic cells *in vivo* or *ex vivo*. This section applies to non-replicative vectors.

PRODUCTION

VECTOR CONSTRUCTION

A typical vector is composed of:
- the minimal genome from parental viruses containing the structural genetic elements shown to be indispensable for vector production;
- the required regulatory genetic elements for expression of the genetic insert (for example, long terminal repeats (LTRs));
- the genetic insert.

The vector construction is designed to prevent the generation of replication-competent viruses.

VECTOR PRODUCTION

The production method shall have been shown to yield a vector of consistent quality. Unless otherwise justified and authorised, the packaging or producer cells shall have undergone no more cell doublings from the master cell bank (MCB) than were used to prepare the vector shown in clinical trials to be satisfactory with respect to safety and efficacy.

The genetic and phenotypic stability of the packaging or producer cells at or beyond the maximum number of cell doublings used for production is assessed by suitable methods.

Vectors are produced in continuous cell lines (*5.2.3*) using a cell-bank system. Production may involve either stably or transiently transfected cells.

DEFINITIONS

Packaging cells A source cell line stably transfected with plasmids containing the viral genes necessary for production of empty vector particles: *gag*, *pol*, *env*.

Producer cells Contain the viral genes and expression cassette necessary for vector production.
- In stable production systems, the producer cells are generated by stable transfection of the packaging cell line by a transfer plasmid containing the sequence of interest.
- In transient production systems, the producer cells are generated at the time of manufacture by simultaneous transfection of the source cell line with both the viral genes and the transgene expression plasmid, or by transient transfection of the packaging cell line by a transfer plasmid containing the sequence of interest.

PRODUCTION INTERMEDIATES

Packaging cells

Copy number
The genomic DNA is isolated and purified from a known number of cells and the *gag*, *pol* and *env* genes copy number is determined by a suitable method such as quantitative PCR (*2.6.21*).

Sequence integrity of the viral genes
Complete nucleotide sequencing of the inserted viral genes and their regulatory elements is performed.

Genetic stability
Genetic stability of the packaging cells is verified at or beyond the maximum number of cell doublings used for production.

Plasmids

Production of the vector requires the use of plasmid intermediates. For each plasmid DNA used during

production, a complete description is established, including identification, source, means of isolation and nucleotide sequence. The source and function of component parts of these plasmids, such as the origin of replication, viral and eukaryotic promoters and genes encoding selection markers, are documented.

Production of plasmid intermediates is based on a bacterial cell-bank system. The MCB complies with the requirements of the section Bacterial cells used for the manufacture of plasmid vectors for human use. Plasmids are purified by suitable techniques.

Only plasmid batches that comply with the following requirements may be used for the production of the vector.

Identification
Plasmids are identified by restriction enzyme analysis, sequencing or NAT (*2.6.21*).

Genomic integrity
Genomic integrity of the plasmid is verified by suitable methods such as restriction enzyme analysis of the viral genes, the genetic insert and their respective regulation elements.

Plasmid DNA
The following indications are given as examples.

DNA concentrations greater than 500 ng/mL may be determined using absorbance measurement at 260 nm. A 50 µg/mL double-stranded DNA solution has an absorbance of 1 (specific absorbance 200).

DNA concentrations less than 500 ng/mL are determined following incubation with fluorescent dyes that bind specifically to double-stranded DNA, using a reference standard of DNA to establish a calibration curve.

Liquid chromatography may also be used to determine the concentration of plasmid DNA using a reference standard. In some cases, capillary electrophoresis is also acceptable.

Residual host-cell DNA
The content of residual host-cell DNA is determined using a suitable method, unless the production process has been validated to demonstrate suitable clearance. Quantitative PCR is recommended for its sensitivity and specificity, but other suitable techniques may also be used.

Bacterial endotoxins (*2.6.14*)
Less than the limit approved for the particular preparation.

Sterility (*2.6.1*)
It complies with the test for sterility.

Producer cells used in a stable production system

Copy number
The copy number of the integrated viral genes and expression cassette is determined by a suitable method.

Genetic stability
Genetic stability of the producer cells at or beyond the maximum number of cell doublings used for production is confirmed.

Sequence integrity of the viral genes and expression cassette
Complete nucleotide sequencing of the inserted viral genes, the expression cassette and their respective regulation elements (for example, LTRs, promoters, psi sequence, polyadenylation signal) is performed.

Replication-competent viruses
The detection of replication-competent viruses is performed by suitable methods. Detection may be based on a co-cultivation for several cell doublings of the producer cells with a permissive cell line, followed by detection (either by observation of a cytopathic or haemadsorbing effect on indicator cells like PG4 S+L-, by detection using indicator cell lines by NAT (*2.6.21*) or by marker-rescue assay). Positive controls are included in each assay to monitor its sensitivity. No replication competent viruses are found.

PRODUCTION AND HARVEST
All processing of the cell bank and subsequent cell cultures is done in an area with a suitable containment level where no other cells or vectors are handled at the same time.
Any material of human or animal origin used in the preparation of cell suspensions and culture media must be qualified. It is preferable to have a substrate free from antibiotics during production. Unless otherwise justified and authorised, at no stage during production is penicillin or streptomycin used.

Each single harvest that complies with the following requirements may be used in the preparation of the purified harvest.

Identification
The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Vector concentration
The titre of infectious vector and/or the concentration of vector particles in single harvests is determined.

Extraneous agents
Each single harvest complies with the tests for extraneous agents (*2.6.16*).

Control cells
Where a transient production process is used, control cells comply with a test for identification (*5.2.3*) and a test for extraneous agents (*2.6.16*).

PURIFIED HARVEST
Several single harvests may be pooled before purification. Purified harvests that comply with the following requirements may be used in the preparation of the final bulk.

Identification
The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Genomic integrity
Genomic integrity of the vector is verified by a suitable method.

Vector concentration
The infectious particle titre is determined by a suitable method, for example infection of permissive cells followed by quantitative NAT (for example, quantitative PCR), Southern blot or protein expression. For lentivirus vectors, the physical titre is measured, for example by ELISA (p24).

Replication-competent viruses
Detection of replication-competent viruses is performed by suitable methods. It is generally performed by amplification on permissive cells followed by NAT (*2.6.21*), by detection of a viral antigen (for example, p24 by ELISA) or by marker-rescue assay. Positive controls are included in each assay to monitor its sensitivity.

Detection of replication-competent viruses is performed on the purified harvest or on the final lot. No replication-competent viruses are found.

Residual host-cell protein
The concentration of residual host-cell protein is determined by a suitable immunochemical method (*2.7.1*), unless the process has been validated to demonstrate suitable clearance.

Residual host-cell DNA
The content of residual host-cell DNA is determined using a suitable method, unless the process has been validated to demonstrate suitable clearance. Quantitative PCR is recommended for its sensitivity and specificity, but other suitable techniques may also be used.

Residual reagents
Where reagents are used during production, tests for these substances are carried out on the purified harvest, unless the process has been validated to demonstrate suitable clearance.

Residual antibiotics
Where antibiotics are used during the production process, their residual concentration is determined by a microbiological assay (adapted from general method *2.7.2*) or by other suitable methods (for example, liquid chromatography), unless the process has been validated to demonstrate suitable clearance.

Residual plasmids
Where a transient production process is used, the concentration of residual contaminating plasmids must be quantified.

FINAL BULK
Several purified harvests may be pooled during preparation of the final bulk. A stabiliser and other excipients may be added. The formulated product is filtered through a bacteria-retentive filter.

Only a final bulk that complies with the following requirement may be used in the preparation of the final lot.

Sterility (*2.6.1*)
It complies with the test for sterility.

FINAL LOT
Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for bovine serum albumin (when bovine serum is used to manufacture the vector) and replication-competent viruses have been carried out with satisfactory results on the purified harvest, they may be omitted on the final lot.

IDENTIFICATION
Retroviridae-derived vectors are identified by NAT (*2.6.21*), immunochemical methods (*2.7.1*) or restriction enzyme analysis.

TESTS
Osmolality (*2.2.35*)
Within the limits approved for the particular preparation.

pH (*2.2.3*)
Within the limits approved for the particular preparation.

Extractable volume (*2.9.17*)
It complies with the test for extractable volume.

Residual moisture (*2.5.12*)
Within the limits approved for the particular freeze-dried preparation.

Bovine serum albumin
Where bovine serum has been used during production, not more than the limit approved for the particular preparation, determined by a suitable immunochemical method (*2.7.1*).

Replication-competent viruses
Detection of replication-competent viruses is performed by suitable methods. It is generally performed by amplification on permissive cells followed by NAT (*2.6.21*), detection of a viral antigen (for example, p24 by ELISA) or marker-rescue assay. Positive controls are included in each assay to monitor its sensitivity.

Detection of replication-competent viruses is performed on the purified harvest or on the final lot. No replication-competent viruses are found.

Sterility (*2.6.1*)
It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*)
Less than the limit approved for the particular preparation.

ASSAY
Vector-particle concentration
Physical titration is performed by a suitable technique (for example, immunochemical methods (*2.7.1*) or NAT (*2.6.21*)). Use an appropriate vector reference standard to validate each assay.

Infectious vector titre
Titrate the preparation to be examined by inoculation into cell cultures. Titrate an appropriate vector reference standard to validate each assay.

The infectious vector titre of the preparation to be examined is not less than the minimum titre stated on the label.

The assay is invalid if:
- the confidence interval ($P = 0.95$) of the logarithm of the vector concentration is greater than a value authorised by the competent authority;
- the infectious vector titre of the reference standard is outside limit values defined by a control chart.

Ratio of vector-particle concentration to infectious vector titre
Within the limits approved for the particular product, where applicable.

Expression of the genetic insert product
The expression of the genetic insert product(s) is determined wherever possible, following inoculation of cell cultures with the product at a predetermined multiplicity of infection, by suitable immunochemical (*2.7.1*) or biochemical assays or by flow cytometry (*2.7.24*).

Biological activity
Unless otherwise justified and authorised, biological activity is determined by a suitable *in vitro* or *in vivo* test.

LABELLING
The label states:
- the minimum vector titre per human dose;
- the recommended human dose;
- for freeze-dried preparations:
  - the name or composition and the volume of the reconstituting liquid to be added;
  - the time within which the product is to be used after reconstitution.

ADENO-ASSOCIATED-VIRUS VECTORS FOR HUMAN USE

DEFINITION
Adeno-associated-virus (AAV) vectors for human use are freeze-dried or liquid preparations of recombinant AAV (rAAV), genetically modified to transfer genetic material to human somatic cells *in vivo* or *ex vivo*.

PRODUCTION
VECTOR CONSTRUCTION
RAAV vectors are developed by replacement of the *rep* and *cap* genes with the genetic insert of interest. The inverted terminal repeat (ITR) sequences are retained in the rAAV

vector since these are the only AAV sequences absolutely required in *cis* to function as the origin of replication. The *rep* and *cap* genes are required in *trans* and function for replication and packaging respectively. In summary, the rAAV vector contains the ITRs and the genetic insert.

Wild-type AAV normally replicate only in the presence of helper functions, provided by a coinfecting adenovirus or herpes virus. Therefore, there are different approaches to the manufacture of an AAV vector. The manufacturing strategy chosen is designed to minimise the risk for the generation of replication-competent AAV vectors and effectively eliminate helper viruses that might be used during production.

VECTOR PRODUCTION

The production method shall have been shown to yield a vector of consistent quality and stability.

To produce AAV vectors, several strategies are currently used, for example:

— transient co-transfection of a cell line with plasmids containing the ITRs and the genetic insert, *rep* and *cap* genes and helper functions;
— infection with a replication-deficient helper virus of a producer cell line harbouring *rep* and *cap* genes, the ITRs and the genetic insert;
— infection of a permissive cell line with 1 or several production viruses encoding *rep* and/or *cap* and/or the genetic insert and the ITRs, and that may or may not provide helper functions (helper viruses and baculoviruses, respectively).

Depending on the strategy used to produce AAV vectors, different production intermediates are required (plasmids, viruses used for production, packaging cells).

The occurrence of replication-competent AAV may be significant when regions of homology exist between the genomes of the production intermediates and the rAAV vector. This occurrence may be minimised by reducing the homology between these genomes to a minimum. The use of production intermediates with no sequence homology is recommended for production.

The genetic and phenotypic stability of the vector at or beyond the maximum number of passage levels used for production is assessed by suitable methods.

PRODUCTION INTERMEDIATES

Viruses used for production and the rAAV vector are produced in continuous cell lines (*5.2.3*) using a seed lot and a cell-bank system.

Packaging and producer cells

Copy number

The genomic DNA is isolated and purified from a known number of cells and the copy number of the inserted viral genes and of the expression cassette is determined by a suitable method such as quantitative PCR (*2.6.21*).

Sequence integrity of the viral genes and expression cassette

Complete nucleotide sequencing of the inserted viral genes, of their regulatory elements and where applicable, of the expression cassette is performed.

Genetic stability

Genetic stability of the cells is verified at or beyond the maximum number of cell doublings used for production.

Wild-type AAV

The absence of wild-type AAV is verified using NAT (*2.6.21*).

Plasmids

Production of the AAV vector by transient co-transfection requires the use of plasmid intermediates. For each plasmid DNA used during production, a complete description is established, including identification, source, means of isolation and nucleotide sequence. The source and function of component parts of these plasmids, such as the origin of replication, viral and eukaryotic promoters and genes encoding selection markers, are documented.

Production of plasmid intermediates is based on a bacterial cell-bank system. The master cell bank complies with the requirements of the section Bacterial cells used for the manufacture of plasmid vectors for human use. Plasmids are purified by suitable techniques.

Only plasmid batches that comply with the following requirements may be used for the production of the AAV vector.

Identification

Plasmids are identified by restriction enzyme analysis, sequencing or NAT (*2.6.21*).

Genomic integrity

Genomic integrity of the plasmid is verified by suitable methods such as restriction enzyme analysis of the region corresponding to *rep*, *cap* and the expression cassette.

Plasmid DNA

The following indications are given as examples.

DNA concentrations greater than 500 ng/mL may be determined using absorbance measurement at 260 nm. A 50 µg/mL double-stranded DNA solution has an absorbance of 1 (specific absorbance 200).

DNA concentrations less than 500 ng/mL are determined following incubation with fluorescent dyes that bind specifically to double-stranded DNA, using a reference standard of DNA to establish a calibration curve.

Liquid chromatography may also be used to determine the concentration of plasmid DNA using a reference standard. In some cases, capillary electrophoresis is also acceptable.

Residual host-cell DNA

The content of residual host-cell DNA is determined using a suitable method, unless the production process has been validated to demonstrate suitable clearance. Quantitative PCR is recommended for its sensitivity and specificity, but other suitable techniques may also be used.

Bacterial endotoxins (*2.6.14*)

Less than the limit approved for the particular preparation.

Sterility (*2.6.1*)

It complies with the test for sterility.

Viruses used for production

Their production is based on a seed lot and a cell-bank system or, where applicable (for example, for baculoviruses), on a transient system. The strain of virus used is identified by historical records that include information on its origin and its subsequent manipulation, notably deleted or modified regions. The nucleotide sequence of the viruses is documented.

Only a virus used for production that complies with the following requirements may be used.

Identification

Viruses used for production are identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Genomic integrity
Genomic integrity of the virus used for production is verified by suitable methods such as restriction enzyme analysis. Where viruses are modified to express *rep* or *cap* genes or the expression cassette, genomic integrity is assessed by sequencing or by quantitative PCR of these regions.

Genetic stability
Where a stable production system is used, genetic stability is verified at or beyond the maximum number of cell doublings used for production.

Virus titration
The infectious titre is determined by a suitable assay.

Wild-type AAV
Where applicable, the absence of wild-type AAV in helper virus seed lots is verified using NAT (*2.6.21*).

Replication-competent viruses
Detection of replication-competent viruses is performed by suitable methods. No replication-competent viruses are found.

Extraneous agents (*2.6.16*)
It complies with the test for extraneous agents. In addition, detection of potential contamination with specific insect viruses is required where applicable.

PRODUCTION AND HARVEST
All processing of the cell bank and subsequent cell cultures is done in an area with a suitable classified space with appropriate containment level where no other cells, viruses or vectors are handled at the same time. Any material of human or animal origin used in the preparation of cell suspensions and culture media is qualified. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production, and at no stage during production is penicillin or streptomycin used. A portion of the production cell cultures is set aside as uninfected cell cultures (control cells).

Each single harvest that complies with the following requirements may be used in the preparation of the purified harvest.

Identification
The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Vector concentration
The titre of infectious vector and the concentration of vector particles in single harvests are determined.

Extraneous agents (*2.6.16*)
The single harvest complies with the tests for extraneous agents.

Control cells
Control cells comply with a test for identification (*5.2.3*) and a test for extraneous agents (*2.6.16*) and specific insect viruses, where insect cell lines are used for production.

PURIFIED HARVEST
Several single harvests may be pooled before the purification process. The purification process is validated to demonstrate satisfactory removal of impurities.

Purified harvests that comply with the following requirements may be used in the preparation of the final bulk.

Identification
The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

Genetic characterisation
The following tests are carried out.
- The entire genome of the vector is sequenced for a suitable number of production runs at the level of the purified harvest or final bulk and the analytically determined sequence is compared to the theoretical sequence based on vector construction and available databases.
- Genomic integrity is checked on the vector DNA. PCR analysis may be used.

Vector concentration
The titre of infectious vector and the concentration of vector particles are determined.

Residual viruses used for production
Residual viruses used for production are assessed by plaque assays or tissue culture infective dose 50 ($TCID_{50}$) on permissive cell lines or by quantitative PCR, according to the production system used.

Residual proteins
The concentrations of residual host-cell and/or viral proteins are determined by a suitable immunochemical method (*2.7.1*), unless the process has been validated to demonstrate suitable clearance.

Residual DNA
The content of residual producer-cell DNA and of residual DNA from intermediates such as plasmids and production viruses where applicable, is determined using a suitable method, unless the process has been validated to demonstrate suitable clearance. Quantitative PCR is recommended for its sensitivity and specificity, but other suitable techniques may also be used.

Residual reagents
Where reagents are used during production, tests for these substances are carried out on the purified harvest, unless the process has been validated to demonstrate suitable clearance.

Residual antibiotics
Where antibiotics are used during the production process, their residual concentration is determined by a microbiological assay (adapted from general method *2.7.2*) or by other suitable methods (for example, liquid chromatography), unless the process has been validated to demonstrate suitable clearance.

FINAL BULK
Several purified harvests may be pooled during preparation of the final bulk. A stabiliser and other excipients may be added. The formulated product is filtered through a bacteria-retentive filter.

Only a final bulk that complies with the following requirement may be used in the preparation of the final lot.

Sterility (*2.6.1*)
It complies with the test for sterility.

FINAL LOT
Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for bovine serum albumin (when bovine serum is used to manufacture the vector), replication-competent AAV and residual viruses used for production have been carried out with satisfactory results on the final bulk, they may be omitted on the final lot.

IDENTIFICATION
The vector is identified by immunochemical methods (*2.7.1*), NAT (*2.6.21*) or restriction enzyme analysis.

TESTS

Osmolality (*2.2.35*)
Within the limits approved for the particular preparation.

pH (*2.2.3*)
Within the limits approved for the particular preparation.

Extractable volume (*2.9.17*)
It complies with the test for extractable volume.

Residual moisture (*2.5.12*)
Within the limits approved for the particular freeze-dried product.

Bovine serum albumin
Where bovine serum has been used during production, not more than the limit approved for the particular preparation, determined by a suitable immunochemical method (*2.7.1*).

Replication-competent AAV concentration
Within the limits approved by the competent authority.

Detection of replication-competent AAV is performed by a replication assay on a permissive cell line previously infected with a helper virus and analysis of the replicative forms by Southern blot on low-molecular-weight DNA, or by detection of the *rep* gene by quantitative PCR.

Vector aggregates
Vector aggregates are determined by suitable methods (for example, light scattering).

Sterility (*2.6.1*)
It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*)
Less than the limit approved for the particular preparation.

ASSAY

Vector-particle concentration
Vector-particle concentration is determined using a suitable method such as quantitative PCR by comparison with a standard curve obtained using the recombinant AAV plasmid or an AAV reference standard. This concentration is within the limits approved for the particular product.

Infectious vector titre
Titrate the preparation to be examined by inoculation into cell cultures. Titrate an appropriate vector reference standard to validate each assay.

The infectious vector titre of the preparation to be examined is not less than the minimum amount stated on the label.

The assay is invalid if:
- the confidence interval ($P = 0.95$) of the logarithm of the vector concentration is greater than a value authorised by the competent authority;
- the infectious vector titre of the reference standard is outside limit values defined by a control chart.

Ratio of vector-particle concentration to infectious vector titre
Within the limits approved for the particular product.

Expression of the genetic insert product
The expression of the genetic insert product is determined wherever possible, following inoculation of cell cultures with the product at a predetermined multiplicity of infection, by suitable immunochemical (*2.7.1*) or biochemical assays or by flow cytometry (*2.7.24*).

Biological activity
Unless otherwise justified and authorised, biological activity is determined by a suitable *in vitro* or *in vivo* test.

LABELLING

The label states:
- the content of active substance;
- the recommended human dose;
- for freeze-dried preparations:
  - the name or composition and the volume of the reconstituting liquid to be added;
  - the time within which the product is to be used after reconstitution.

O. Functionality-related Characteristics of Excipients

(Ph. Eur. general texts 5.15)

This chapter and the Functionality-related characteristics (FRCs) sections in individual monographs are not mandatory and are published for information and guidance.

PREAMBLE

Excipients that have previously been evaluated for safety are used in the formulation of pharmaceutical preparations to bring functionality to the formulation. The intended function of an excipient is to guarantee the required physico-chemical and biopharmaceutical properties of the pharmaceutical preparation.

The functionality of an excipient is determined by its physical and chemical attributes and, in some cases, also by its content of by-products or of additives used to improve the intended functionality. In addition, the functionality may depend on complex interactions between the constituents of the formulation and stresses related to the process. Excipient functionality can therefore be evaluated only in the context of a particular formulation and manufacturing process, frequently by the use of a number of analytical methods.

Pharmaceutical development should be science-based and ensure a quality medicinal product. It is defined in the current ICH guideline Q8 Pharmaceutical Development. Its purpose is to provide justification for the dosage form selected, the qualitative and quantitative composition of the medicinal product, the manufacturing process, the critical quality attributes (CQAs) of the constituents and medicinal product, and the critical process parameters (CPPs). The 'quality by design' (QbD) concept described in the ICH Q8 guideline requires a comprehensive understanding of the chemical and physical nature of the individual active substance(s) and excipients, and of the way their attributes interact in the formulation and with the manufacturing process.

Pharmaceutical development includes identification of which excipient quality attributes are critical.

A CQA is a physical, chemical, biological or microbiological property or characteristic that must be within appropriate limits to ensure the desired medicinal product quality.

Monographs of the European Pharmacopoeia on excipients are designed to ensure acceptable quality for users. Information on the characters of the excipient, and requirements concerning identity, chemical and microbiological purity and physical characteristics associated with the chemical structure, such as optical rotation, are given in individual monographs and in the general monograph *Substances for pharmaceutical use (2034)*.

Certain excipient attributes, such as the particle size of an excipient intended for a solid dosage form or the molecular mass of a polymeric material used as a viscosity-increasing agent, may however relate to functionality in a more general

sense. These attributes are called functionality-related characteristics (FRCs). When the pharmaceutical development work of a specific product has identified the existence of one or more critical FRCs for an excipient, they are considered to be CQAs for that excipient and should be controlled accordingly.

Knowledge of FRCs may facilitate the application of process analytical technology (PAT).

FRCs are included in excipient monographs to aid excipient manufacturers and users in establishing specifications based on standard analytical methods. They provide a common language to support the supply of excipients with specified properties. FRCs may be stated (in the certificate of analysis, for example) by the excipient manufacturer with a reference to the Pharmacopoeia monograph, thus indicating the method used to test a particular characteristic. The FRCs section in individual monographs contains FRCs that are known to have an impact on the functionality of the excipient for the stated uses. The uses and the FRCs listed are not exhaustive due to the multiple uses of many excipients and the development of new uses.

REGULATORY GUIDANCE

According to current regulatory guidelines, for example the ICH Q8 guideline, the marketing authorisation application should discuss the excipients chosen, their concentration, and the attributes that can influence the medicinal product quality or manufacturability relative to the respective function of each excipient. The ability of excipients to provide their intended functionality and to perform throughout the intended medicinal product shelf life should also be demonstrated. The information on excipient performance can be used as appropriate to justify the choice and quality attributes of the excipient.

During pharmaceutical development, the attributes that are critical to the manufacturing process and quality of the medicinal product are identified. Having identified the critical attributes of the excipients, preferably by a risk-based approach, pharmaceutical development may establish the acceptable range of the critical material attributes including both the physical and the chemical property variation. The FRCs concerned may not be properties controlled by the excipient manufacturer and could therefore be variable. The design of a robust manufacturing process for the medicinal product that limits the effect of the normal excipient variability is preferable.

Evaluation of the physical and chemical grades and, where appropriate, the setting of a specification for the critical attributes and thus the critical FRCs, is part of the pharmaceutical development irrespective of the non-mandatory character of FRCs. This evaluation should be seen in light of regulatory guidance on pharmaceutical development and the appropriate acceptance criteria should be based on an understanding of the extent to which the variation of the critical FRCs can have an impact on the quality of the medicinal drug product. An acceptable range of FRCs may be established within the limits of the design space. The design space may be described as a space in which the quality attributes of the constituents and the process parameters may vary without modification of the quality of the medicinal product.

PHYSICAL GRADES

Excipients that are particulate solids can be available in a variety of physical grades, for example with regard to particle-size distribution, which is usually controlled by the excipient supplier. However, FRCs for these excipients may concern a wide range of properties, resulting from solid-state properties and properties of the particulate solid, which may not be controlled by the excipient supplier.

Properties of particulate solids include for example particle-size distribution, specific surface area, bulk density, flowability, wettability and water sorption. Depending on the size range, the particle-size distribution can be determined by sieve analysis (see general chapter *2.9.38. Particle-size distribution estimation by analytical sieving*) or instrumental methods, for example *2.9.31. Particle size analysis by laser light diffraction*. The method described in general chapter *2.9.26. Specific surface area by gas adsorption* is based on the Brunauer-Emmett-Teller (BET) technique. Methods to characterise flowability and bulk density of powders are described in general chapters *2.9.36. Powder flow* and *2.9.34. Bulk density and tapped density*. Solid-state properties may have an impact on the wettability (see general chapter *2.9.45. Wettability of porous solids including powders*) and water-solid interactions (see general chapter *2.9.39. Water-solid interactions: determination of sorption-desorption isotherms and of water activity)* of particulate solids.

Examples of solid-state properties to be considered in the development of solid dosage forms include polymorphism, pseudopolymorphism, crystallinity and density. Techniques to study them are given in general chapters *5.9. Polymorphism*, *5.16. Crystallinity* and *2.2.42. Density of solids*.

CHEMICAL GRADES

Excipients that are available in different chemical grades are of natural, semi-synthetic or synthetic origin. Individual monographs usually control the chemical composition of excipients that are composed of a mixture of related compounds, for example the composition of fatty acids in vegetable oils or surfactants. There are, however, individual monographs in the Pharmacopoeia each describing a class of polymeric materials that may vary in their composition with regard to the structure of homopolymers, block polymers and copolymers, the degree of polymerisation, the molecular mass and mass distribution, the degree of substitution and in some cases even different substituents on the polymer backbone. This variation may, however, have a profound effect on the functionality of the excipient and should be subject to investigations during the pharmaceutical development, preferably to establish the acceptable range of each attribute being critical to the manufacturing process and quality of the medicinal product.

FUNCTIONALITY-RELATED CHARACTERISTICS SECTION IN MONOGRAPHS

Monographs on excipients may have a section entitled 'Functionality-related characteristics'. This section is included for information for the user and is not a mandatory part of the monograph. The section gives a statement of characteristics that are known to be relevant for certain uses of the excipient. The use for which the characteristic is relevant is stated. For other uses, the characteristic may be irrelevant. For this reason, the section should not be seen simply as a supplement to the monograph. It is the responsibility of the manufacturer of the medicinal product to decide how the information on FRCs will be applied in the manufacturing process in light of the use of the excipient and data from pharmaceutical development.

The information on the FRCs may be given in different ways:

— name of the FRC;

— name of the FRC and a recommended method for its determination, referring wherever possible to a general chapter of the Pharmacopoeia;
— name of the FRC with a recommended method for its determination and typical values, which may be in the form of tolerances from the nominal value.

A given characteristic may be the subject of a mandatory requirement in the monograph. If it is relevant for certain uses, it is also referred to in the FRCs section as a relevant characteristic that the manufacturer of the medicinal product may choose to specify for the grade used of a particular pharmaceutical preparation.

The section on FRCs is intended to reflect current knowledge related to the major uses of an excipient. In view of the multiple uses of some excipients and the continuous development of new uses, the section may not be complete. In addition, the methods cited for the determination of a particular characteristic are given as recommendations for methods that are known to be satisfactory for the purpose, and the use of other methods is not excluded.

PHARMACOPOEIAL HARMONISATION

A number of excipient monographs are subject to pharmacopoeial harmonisation among the European, Japanese and United States pharmacopoeias (see general chapter *5.8. Pharmacopoeial harmonisation*). Introduction of the FRCs section in the monographs of the European Pharmacopoeia means that the presentation of harmonised monographs differs. Tests for physical and chemical attributes regarded as both quality-related and functionality-related in the European Pharmacopoeia are, in the 2 other pharmacopoeias, included only in the body of the monograph. The different format has no implications on the specification of excipient characteristics for the manufacturer of the medicinal product. Current regulatory guidance recommends the identification and specification of only such critical attributes that impact the manufacturing process and the quality of the medicinal product. The different legal environments of the 3 pharmacopoeias allow for different formats of the monographs without affecting the pharmacopoeial harmonisation status.

GLOSSARY

Critical characteristic or critical quality attribute (CQA)
A physical, chemical, biological or microbiological property or characteristic that must be within appropriate limits or an appropriate range or distribution to ensure the desired product quality.

Critical process parameter (CPP)
A process parameter whose variability has an impact on a critical quality attribute and therefore should be monitored or controlled to ensure the process produces the desired quality.

Design space
The multidimensional combination and interaction of input variables (e.g. material attributes) and process parameters that have been demonstrated to provide assurance of quality.

Functionality-related characteristic (FRC)
A controllable physical or chemical characteristic of an excipient that is shown to impact on its functionality.

Process analytical technology (PAT)
A system for designing, analysing and controlling manufacturing through timely measurements (i.e. during processing) of critical quality and performance attributes of raw and in-process materials and processes with the goal of ensuring final product quality.

Quality by design (QbD)
A systematic approach to development that begins with predefined objectives and emphasises product and process understanding and process control, based on sound science and quality risk management.

P. Guidelines for Using the Test for Sterility

(Ph. Eur. general texts 5.1.9)

The purpose of the test for sterility (*2.6.1*), as that of all pharmacopoeial tests, is to provide an independent control analyst with the means of verifying that a particular material meets the requirements of the European Pharmacopoeia. A manufacturer is neither obliged to carry out such tests nor precluded from using modifications of, or alternatives to, the stated method, provided he is satisfied that, if tested by the official method, the material in question would comply with the requirements of the European Pharmacopoeia.

PRECAUTIONS AGAINST MICROBIAL CONTAMINATION

Aseptic conditions for performance of the test can be achieved using, for example, a class A laminar-air-flow cabinet located within a class B clean room, or an isolator

GUIDANCE TO MANUFACTURERS

The level of assurance provided by a satisfactory result of a test for sterility (the absence of contaminated units in the sample) as applied to the quality of the batch is a function of the homogeneity of the batch, the conditions of manufacture and the efficiency of the adopted sampling plan. Hence for the purpose of this text a batch is defined as a homogeneous collection of sealed containers prepared in such a manner that the risk of contamination is the same for each of the units contained therein.

In the case of terminally sterilised products, physical proofs, biologically based and automatically documented, showing correct treatment throughout the batch during sterilisation are of greater assurance than the sterility test.
The circumstances in which parametric release may be considered appropriate are described under *5.1.1. Methods of preparation of sterile products*. The method of media-fill runs may be used to evaluate the process of aseptic production. Apart from that, the sterility test is the only analytical method available for products prepared under aseptic conditions and furthermore it is, in all cases, the only analytical method available to the authorities who have to examine a specimen of a product for sterility.

The probability of detecting micro-organisms by the test for sterility increases with their number present in the sample tested and varies according to the readiness of growth of micro-organism present. The probability of detecting very low levels of contamination even when it is homogenous throughout the batch is very low. The interpretation of the results of the test for sterility rests on the assumption that the contents of every container in the batch, had they been tested, would have given the same result. Since it is manifest that every container cannot be tested, an appropriate sampling plan should be adopted. In the case of aseptic production, it is recommended to include samples filled at the beginning and at the end of the batch and after significant intervention.

OBSERVATION AND INTERPRETATION OF RESULTS

Conventional microbiological/biochemical techniques are generally satisfactory for identification of micro-organisms recovered from a sterility test. However, if a manufacturer wishes to use condition (d) as the sole criterion for invalidating a sterility test, it may be necessary to employ sensitive typing techniques to demonstrate that a micro-organism isolated from the product test is identical to a micro-organism isolated from the test materials and/or the testing environment. While routine microbiological/biochemical identification techniques can demonstrate that 2 isolates are not identical, these methods may not be sufficiently sensitive or reliable enough to provide unequivocal evidence that 2 isolates are from the same source. More sensitive tests, for example molecular typing with RNA/DNA homology, may be necessary to determine that micro-organisms are clonally related and have a common origin.

Q. Elemental Impurities

(Ph. Eur. general text 5.20)

The International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) has adopted the ICH Q3D guideline for elemental impurities in medicinal products.

The European Pharmacopoeia (Ph. Eur.) applies this guideline to medicinal products (referred to hereunder and in the ICH Q3D guideline as 'drug products'), with the exception of products for veterinary use, unlicensed preparations and products excluded from the scope of the guideline. The guideline prescribes a permitted daily exposure (PDE) according to the route of administration for elements of toxicological concern which may be present in medicinal products. The guideline also describes some acceptable approaches to establishing concentrations of elemental impurities in medicinal products or components that would ensure that the PDEs for these impurities are not exceeded.

Parts of the introduction and the scope of the guideline are reproduced hereunder, and the full text is available from the ICH website.

The drug products containing purified proteins and polypeptides (including proteins and polypeptides produced from recombinant or non-recombinant origins), their derivatives, and products of which they are components (e.g., conjugates) are within the scope of the guideline, as are drug products containing synthetically produced polypeptides, polynucleotides, and oligosaccharides.

The guideline does not apply to herbal products, radiopharmaceuticals, vaccines, cell metabolites, DNA products, allergenic extracts, cells, whole blood, cellular blood components or blood derivatives including plasma and plasma derivatives, dialysate solutions not intended for systemic circulation, and elements that are intentionally included in the drug product for therapeutic benefit. The guideline does not apply to products based on genes (gene therapy), cells (cell therapy) and tissue (tissue engineering). In some regions, these products are known as advanced therapy medicinal products.

The guideline does not apply to drug products used during clinical research stages of development. As the commercial process is developed, the principles contained in the guideline can be useful in evaluating elemental impurities that may be present in a new drug product.

Elemental impurities in drug products may arise from several sources; they may be residual catalysts that were added intentionally in synthesis or they may be present as impurities (e.g., through interactions with processing equipment or container/closure systems or by being present in components of the drug product). Because elemental impurities do not provide any therapeutic benefit to the patient, their levels in the drug product should be controlled within acceptable limits.

An applicant is not expected to tighten the limits based on process capability, provided that the elemental impurities in drug products do not exceed the PDEs. The PDEs established in the guideline are considered to be protective of public health for all patient populations. In some cases, lower levels of elemental impurities may be warranted when levels below toxicity thresholds have been shown to have an impact on other quality attributes of the drug product (e.g., element catalysed degradation of drug substances).

R. Chemometric Methods Applied to Analytical Data

(Ph. Eur. general text 5.21)

The following chapter is published for information only. It is an introduction to the use of chemometric techniques for processing analytical data sets. The objective is to provide indications on good chemometric practice and requirements.

1 GENERAL ASPECTS

1-1 INTRODUCTION

1-1-1 Scope of the chapter

This chapter is an introduction to the use of chemometric techniques for the processing of analytical data sets, which is an area of interest for research, quality control and manufacturing in the pharmaceutical industry. The objective is to provide information on the requirements for good chemometric practice and to also present a selection of established chemometric methods, but not an exhaustive review of these techniques, as refinements and innovations are constantly being introduced. The principles of the proposed methods will be briefly described along with their critical aspects and limitations. Mathematical details and algorithms are mostly omitted and a glossary is provided at the end of the chapter.

1-1-2 Definition

The actual definition of chemometrics is "the chemical discipline that uses mathematical and statistical methods, (a) to design or select optimal measurement procedures and experiments, and (b) to provide maximum chemical information by analysing chemical data".

From a more general point of view, chemometrics is not limited to chemical data and can contribute greatly to system understanding by analysing data, when limited knowledge and theory do not sufficiently explain observations and behaviour. Chemometric methods consist mainly of multivariate data-driven modelling techniques that result in empirical mathematical models that are subsequently used for the indirect prediction of properties of interest.

1-1-3 Background

Applications of chemometrics can be qualitative or quantitative, and it can help the analyst to structure the data set and to recognise hidden variable relationships within the system. However, it should be stressed that although such

data-driven methods may be powerful, they would not replace a verified or established theory if available.

Chemometric methods have revolutionised near-infrared spectroscopy (NIR) and such techniques are now integral components of process analytical technology (PAT) and quality by design (QbD) for use in improved process monitoring and quality control in a variety of fields. Chemometric methods can be found throughout the scientific and technological community, with a principal but non-exclusive focus on life and health sciences such as agriculture, food, pharmacy, chemistry, biochemistry and genomics, but also other industries such as petrochemicals, textiles, sensors and cosmetics, with the potential to expand even further into other domains.

The associated mathematical principles have been understood since the early twentieth century, but chemometrics came of age with the development of digital technology and the related progress in the elaboration of mathematical algorithms. Many techniques and methods are based on geometric data representations, transformations and modelling. Later, mathematical and theoretical developments were also consolidated.

1-1-4 Introducing chemometrics

In chemometrics, a property of interest is evaluated solely in terms of the information contained in the measured samples. Algorithms are applied directly to the data set, and information of interest is extracted with models (modelling or calibration step). Chemometrics is associated with multivariate data analysis, which usually depends less on assumptions about the distribution of the data than many other statistical methods since it rarely involves hypothesis testing. During modelling the most sensitive changes in properties of interest can be amplified, while the less relevant changes in disturbing factors, whatever their origin, i.e. physical, chemical, experimental or instrumental variation, are minimised to the level of noise.

A model in chemometrics is a prediction method and not a formal or simplified representation of a phenomenon from physics, chemistry, etc. The ability of a model to predict properties has to be assessed with regard to its performance. The best model or calibration will provide the best estimations of properties of interest. A useful model is one that can be trusted and used for decision-making, for example. Adoption of a model in decision-making must be based on acceptable, reliable, and well-understood assessment procedures.

In univariate analysis, identified variables in a system are analysed individually. However, in reality, systems tend to be more complex, where interactions and combination effects occur between sample variables and cannot be separated. Multivariate data analysis handles many variables simultaneously and the relationship within or between data sets (typically matrices) has to be rearranged to reveal the relevant information. In multivariate methods, the original data is often combined linearly to account as much as possible for the explainable part of the data and ideally, only noise will remain unmodelled. The model, when properly validated, can be used in place of costly and time-consuming measurements in order to predict new values.

Generally, projection techniques such as principal components analysis (PCA), principal components regression (PCR) or partial least squares regression (PLS) are recommended. However, the approach will be different depending on whether the data has been generated using experimental design (i.e. designed data) or has been collected at random from a given population (i.e. non-designed data). With designed data matrices, the variables are orthogonal by construction and traditional multilinear statistical methods are therefore well suited to describing the data within. However, in non-designed data matrices, the variables are seldom orthogonal, but are more or less collinear, which favours the use of multivariate data analysis.

1-1-5 Qualitative and quantitative data analysis

Qualitative data analysis can be divided into exploration, an unsupervised analysis where data from a new system is to be analysed, and classification, a supervised analysis where class-labels are predicted.

Unsupervised analysis

In exploratory data analysis, multivariate tools are used to gather an overview of the data in order to build hypotheses, select suitable analytical methods and sampling schemes, and to determine how multivariate analysis of current and future data of similar type can be performed. When the first exploratory treatment is finalised, classification can be subsequently carried out in the form of a secondary treatment, where samples are organised into specific groups or classes.

Supervised analysis

Classification is the process of determining whether or not samples belong to the same class as those used to build the model. If an unknown sample fits a particular model well, it is said to be a member of that class. Many analytical tasks fall into this category, e.g. materials may be sorted according to quality, physical grade and so on. Identity testing is a special situation where unknown samples are compared with suitable reference materials, either by direct comparison or indirect estimation, e.g. using a chemometric model.

Quantitative data analysis, on the other hand, mainly consists of calibration, followed by direct application to new and unknown samples. Calibration consists of predicting the mathematical relationship between the property to be evaluated (e.g. concentration) and the variables measured.

1-2 GOOD CHEMOMETRIC PRACTICE

The following notation will be used in the chapter:

X, Y	data sets
X	independent variable
Y	dependent variable
$\mathbf{X}$, $\mathbf{Y}$	matrices
$\mathbf{x}$, $\mathbf{y}$	vectors
x, y	scalar values
i, j	indices, points
x_i	i^{th} value of vector $\mathbf{x}$
$x_{i,j}$	i^{th} and j^{th} value of matrix $\mathbf{X}$
$\mathbf{X}^T$	transpose of matrix $\mathbf{X}$
$\mathbf{X}^{-1}$	inverse (if it exists) of matrix $\mathbf{X}$
$\hat{\mathbf{X}}$	estimate of matrix $\mathbf{X}$
$\lvert\mathbf{X}\rvert$	determinant of (square) matrix $\mathbf{X}$
$\lVert\mathbf{x}\rVert$	norm of vector $\mathbf{x}$
b	regression equation coefficient
e	residuals of X
f	residuals of Y

1-2-1 Figures of merits for regression

In quantitative analysis, building a regression model involves fitting a mathematical relationship to the corresponding independent data (X) and dependent data (Y).
The independent data may represent a collection of signals, i.e. responses from a number of calibration samples, while the dependent data may correspond to the values of an attribute, i.e. the property of interest in the calibration samples. It is advisable to test the regression model with internal and external test sets. The internal test set consists of

samples that are used to build the model (or achieve calibration) by applying resampling within the calibration data and samples that are initially left out of the calibration in order to validate the model. Use of the internal test set is part of model optimisation and model selection. The external independent test set represents data that normally is available after the model has been fixed, thus the external test set challenges the model and tests its robustness for the analysis of future data.

1-2-1-1 Root mean square error of prediction

The link between X and Y is explored through a common set of samples (calibration set) from which both x and y-values have been collected and are clearly known. For a second set of samples (validation set) the predicted y-values are then compared to the reference y-values, resulting in a prediction residual that can be used to compute a validation residual variance, i.e. a measure of the uncertainty of future predictions, which is referred to as root mean square error of prediction (*RMSEP*). This value estimates the average uncertainty that can be expected when predicting y-values for new samples. Since no assumptions concerning statistical error distribution are made during modelling, prediction error cannot be used to report a valuable statistical interval for the predicted values. Nevertheless, *RMSEP* is a good error estimate in cases where both calibration and validation sample sets are representative of future samples.

A confidence interval for predicted y-values would be $\pm\ n \times RMSEP$, with n fixed by the operator. A common choice is $n = 2$. This choice should be dependent on the requirements of the specific analytical method.

Chemometric models can end up with better precision than the reference methods used to acquire calibration and testing data. This is typically observed for water content determinations by NIR and PLS where semi-micro determination titration (*2.5.12*) is the reference method.

1-2-1-2 Standard error of calibration and coefficient of determination

Figures of merit can be calculated to help assess how well the calibration fits the data. Two examples of such statistical expressions are the standard error of calibration (*SEC*) and the coefficient of determination (R^2).

SEC has the same units as the dependent variables and reflects the degree of modelling error, but cannot be used to estimate future prediction errors. It is an indication of whether the calculation using the calibration equation will be sufficiently accurate for its intended purpose. In practice *SEC* has to be compared with the error of the reference method (*SEL, Standard Error of Laboratory*, see Glossary). Usually *SEC* is larger than *SEL*, in particular if modelling does not account for all interferences in the samples or if other physical phenomena are present.

The coefficient of determination (R^2) is a dimensionless measure of how well the calibration fits the data. R^2 can have values between 0 and 1. A value close to 0 indicates that the calibration fails to relate the data to the reference values and as the coefficient of determination increases, the X-data becomes an increasingly more accurate predictor of the reference values. Where there is more than 1 independent variable, adjusted R^2 should be used rather than R^2, since the number of independent variables in the model inflates the latter even if the fraction of variance explained by the model is not increased.

1-2-2 Implementation steps

The implementation of chemometric methods varies case by case depending on the specific requirements of the system to be analysed. The following generic approach can be followed when analysing non-designed data sets:

- in formulating the study problem, define the precise objective of data collection and the expected analysis results;
- investigate the origin and availability of the data. The data set should cover the variation of the explored variable(s) or attribute(s);
- if the available data does not cover the expected variation, prepare and measure samples that fill the gap;
- variable selection: sometimes selecting the right variables can give more robustness and also enhance model accuracy;
- raw data may have to be transformed and mathematical pre-treatments performed;
- elaborate the model through calibration and validation;
- challenge the model and check its performance on new samples or data;
- validate the method according to current pharmaceutical usage and requirements.

1-2-3 Data considerations

1-2-3-1 Sample quality

Careful sample selection increases the likelihood of extracting useful information from the analytical data. Whenever it is possible to actively adjust selected variables or parameters according to an experimental design, the quality of the results is increased. Experimental design (also referred to as design of experiments, DoE) can be used to introduce systematic and controlled changes between samples, not only for analytes, but also for interferences. When modelling, common considerations include the determination of which variables are necessary to adequately describe the samples, which samples are similar to each other and whether the data set contains related sub-groups.

1-2-3-2 Data tables, geometrical representations

Sample responses result in a group of numerical values relating to signal intensities (X-data), i.e. the independent variables. However, it should be recognised that these variables are not necessarily linearly independent (i.e. orthogonal) according to mathematical definitions. These values are best represented in data tables and by convention each sample is associated with a specific row of data. A collection of such rows constitutes a matrix, where the columns are the variables. Samples can then be associated with certain features reflecting their characteristics, i.e. the value of a physical or chemical property or attribute and these data are usually referred to as the Y-data, i.e. the dependent variables. It is possible to add this column of values to the sample response matrix, thereby combining both the response and the attribute of each sample.

When n objects are described by m variables the data table corresponds to an $n \times m$ matrix. Each of the m variables represents a vector containing n data values corresponding to the objects. Each object therefore appears as a point in an m dimensional space described by its m coordinate values (1 value for each variable in the m axes).

1-2-3-3 First assessment of data

Before performing multivariate data analysis, the quality of the sample response can be optionally assessed using statistical tools. Graphical tools are recommended for the 1st visual assessment of the data, e.g. histograms and/or boxplots for variables for evaluation of the data distribution, and scatter plots for detection of correlations. Descriptive statistics are useful for obtaining a rapid evaluation of each variable, taken separately, before starting multivariate

analysis. For example, mean, standard deviation, variance, median, minimum, maximum and lower/upper quartile can be used to assess the data and detect out-of-range values and outliers, abnormal spread or asymmetry. These statistics reveal anomalies in a data table and indicate whether a transformation might be useful or not. Two-way statistics, e.g. correlation, show how variations in 2 variables may correlate in a data table. Verification of these statistics is also useful when reducing the size of the data table, as they help in avoiding redundancies.

1-2-3-4 Outliers

An outlier is a sample that is not well described by the model. Outliers can be *X* or *Y* in origin. They reflect unexpected interference in the original data or measurement error. The predicted data that is very different from the expected value calls into question the suitability of the modelling procedure and the range spanned by the original data. In prediction mode, outliers can be caused by changes in the interaction between the instrument and samples or if samples are outside the model's scope. If this new source of variability is confirmed and is relevant, the corresponding data constitutes a valuable source of information. Investigation is recommended to decide whether the existing calibration requires strengthening (updating) or whether the outliers should be ignored as uncritical or unrelated to the process (i.e. operator error).

In the case of classification an outlier test should be performed on each class separately.

1-2-3-5 Data error

Types of data error include random error in the reference values of the attributes, random error in the collected response data and systematic error in the relationship between the two. Sources of calibration error are problem specific, for example, reference method errors and errors due to either sample non-homogeneity or the presence of non-representative samples in the calibration set. Model selection during calibration usually accounts for only a fraction of the variance or error attributable to the modelled analytical technique. However, it is difficult to assess if this error is more significant than the reference method error or vice versa.

1-2-3-6 Pre-processing and variable selection

The raw data may not be optimal for analysis and are generally pre-processed before performing chemometric calculations to improve the extraction of physical and chemical information.

Interferences, for example background effects, baseline shifts and measurements in different conditions, can impede the extraction of information when using multivariate methods. It is therefore important to minimise the noise introduced by such effects by carrying out pre-processing operations.

A wide range of transformations (scaling, smoothing, normalisation, derivatives, etc.) can be applied to *X*-data as well as *Y*-data for pre-processing prior to multivariate data analysis in order to enhance the modelling. The main purpose of these transformations is focussing the data analysis on the pertinent variability within the data set. For example, pre-processing may involve mean centering of variables so that the mean does not influence the model and thus reduce the model rank.

The selection of the pre-processing is mostly driven by parameters such as type of data, instrument or sample, the purpose of the model and user experience. Pre-processing methods can be combined, for example standard normal variate (SNV) with 1st derivative, as an empirical choice.

1-2-4 Maintenance of chemometric models

Chemometric methods should be reassessed regularly to demonstrate a consistent level of acceptable performance. In addition to this periodical task, an assessment should be carried out for critical parameters when changes are made to application conditions of the chemometric model (process, sample sources, measurement conditions, analytical equipment, software, etc.).

The aim of maintaining chemometric models up-to-date is to provide applications that are reliable over a longer period of use. The extent of the validation required, including the choice of the necessary parameters, should be based on risk analysis, taking into account the analytical method used and the chemometric model.

1-3 ASSESSMENT AND VALIDATION OF CHEMOMETRIC METHODS

1-3-1 Introduction

Current use of the term 'validation' refers to the regulatory context as applied to analytical methods, but the term is also used to characterise a typical computation step in chemometrics. Assessment of a chemometric model consists of evaluating the performance of the selected model in order to design the best model possible with a given set of data and prerequisites. Provided sufficient data are available, a distribution into 3 subsets should always be considered: 1) a learning set to elaborate models, 2) a validation set to select the best model, i.e. the model that enables the best predictions to be made, 3) an independent test set to estimate objectively the performance of the selected final model. Introducing a 3rd set for objective model performance evaluation is necessary to estimate the model error, among other performance indicators. An outline is given below on how to perform a typical assessment of a chemometric model, starting with the initial validation, followed by an independent test validation and finally association/correlation with regulatory requirements.

1-3-2 Assessment of chemometric models

1-3-2-1 Validation during modelling

Typically, algorithms are iterative and perform self-optimisation during modelling through an on-going evaluation of performance criteria and figures of merit. This step is called validation. The performance criteria are specific to the chemometric technique used and to the nature of the analytical data, as well as the purpose of the overall method which includes both the analytical side and the chemometric model. The objective of the validation is to evaluate the model and provide help to select the best performing model. Selected samples are either specifically assigned for this purpose or are selected dynamically through reselection/re-use of data from a previous data set (sometimes called resampling – for clarification, see Glossary). A typical example of data reselection is cross-validation with specific segments, for example 'leave-one-out' cross-validation when samples are only a few, or 'leave-subset-out' cross-validation (Figure 5.21.-1). Another type of resampling is bootstrapping.

1-3-2-2 Assessment of the model

Once the model matches the optimisation requirements, fitness for purpose is assessed. Independent samples not used for modelling or model optimisation are introduced at this stage as an independent test-set in order to evaluate the performance of the model. Ideally, when sufficient data are available, the sample set can be split into 3 subsets comprising 1 learning set for model computation, 1 validation set for optimisation of the model, and 1 test set for

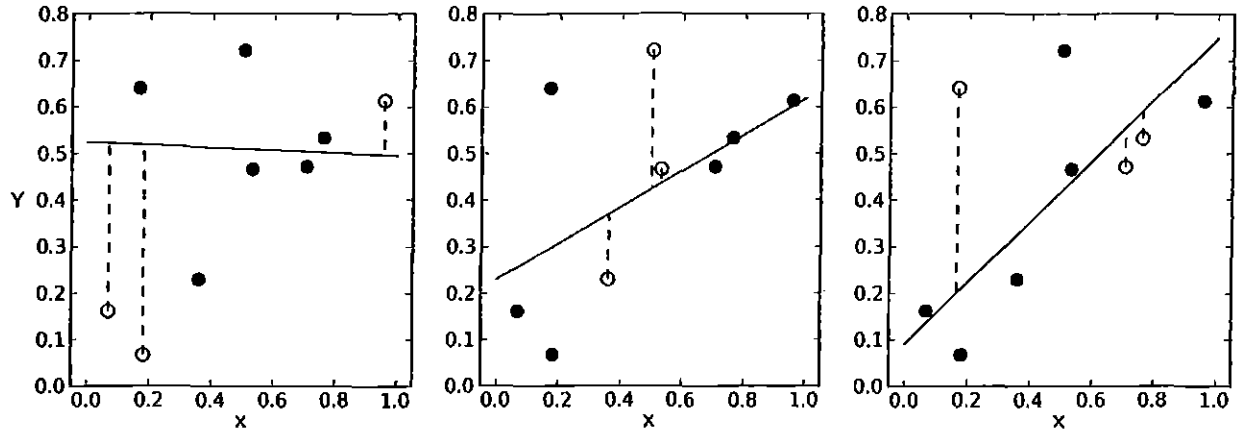


Figure 5.21.-1. – *Cross-validation with leave subset of 3 out applied to linear regression. Regression model data = •. Subset used for test = o. The errors of fit (interrupted lines) are collected to form the cumulated cross-validation error.*

evaluation of the prediction ability, i.e. whether the model is fit for purpose. The 3 subsets are treated independently and their separation should be performed in such a way that model computation is not biased. The aim is to obtain a representative distribution of the samples within the 3 subsets with regard to their properties and expected values.

1-3-2-3 Size and partitioning of data sets

The size of the data set needed for building the calibration is dependent on the number of analytes and interfering properties that needs to be handled in the model. The size of the learning data set for calibration usually needs to be larger when the interfering variations are acquired randomly than when all major interferences are known and they can be varied according to a statistical experimental design.

The lowest possible number of samples needed to cover the calibration range can be estimated from the corresponding design. The size of the independent test set should be in the order of 20-40 per cent of the samples used for the calibration model. However, when representative samples are abundant, the larger the test data set (above 40 per cent), the more reliably the prediction performance can be estimated.

It is common practice to mix learning and model validation sets and as a result, the definitive assessment of the model relies on the separate test set.

1-3-3 Validation according to the regulatory framework

Validation principles and considerations are described in established international guidelines and apply to the validation of analytical methods. However, due to the special nature of data treatment and evaluation, as carried out in most chemometric methods, additional aspects have to be taken into account when validating analytical procedures.

In this context, validation comprises both the assessment of the analytical method performance and the evaluation of the model. In some special cases, it might only be necessary to validate the chemometric model (see section 1-2-4).

1-3-3-1 Qualitative models

For validation of qualitative models, the most critical parameters are specificity and robustness. When not applicable, scientific justification is required.

Specificity

During validation it has to be shown that the model possesses sufficient discriminatory capability. Therefore, a suitable set of materials that pose a risk of mix-up must be defined and justified. If, in addition to chemical identification, other parameters (such as polymorphism, particle size, moisture content, etc.) are relevant, a justification for these parameters should also be included. The selection of materials to be included when validating specificity should be based on logistic considerations (e.g. materials handled close to the process under review, especially those with similar appearance), chemical considerations (e.g. materials with similar structure) and also physical considerations where relevant (e.g. materials with different physical properties). After definition of this set of materials, the discriminatory ability of the chemometric method to reject them must be proven. Therefore, for each material a representative set of samples covering typical variance within the material has to be analysed and evaluated. If the specificity of the chemometric model is insufficient, the parameters of the model should be optimised accordingly and the method revalidated.

Whenever new elements that may potentially affect identification are introduced, e.g. new materials that are handled at the same site and represent a risk of mix-up, a revalidation of specificity should be carried out. This revalidation can be limited to the new element and does not necessarily need to encompass the complete set of elements, whose constituents may not all be affected by the change.

If properties of materials change over time (e.g. batches of materials with lower or higher particle size, lower or higher moisture content etc.) and these changes become relevant, they should also be included as part of the validation. This can be achieved for example, by an amendment to the validation protocol and does not necessarily require a complete revalidation of the chemometric model.

To assess specificity, the number of false-positive and false-negative errors can be evaluated by classification of the test set.

Robustness

For validation of robustness, a comprehensive set of critical parameters (e.g. process parameters such as temperature, humidity, instrumental performance of the analytical equipment) should be considered. The reliability of the analytical method should be challenged by variation of these parameters. It can be advantageous to use experimental design (DoE) to evaluate the method.

To assess robustness the number of correct classifications, correct rejections, false-positive and false-negative errors can be evaluated by classification of samples under robustness conditions.

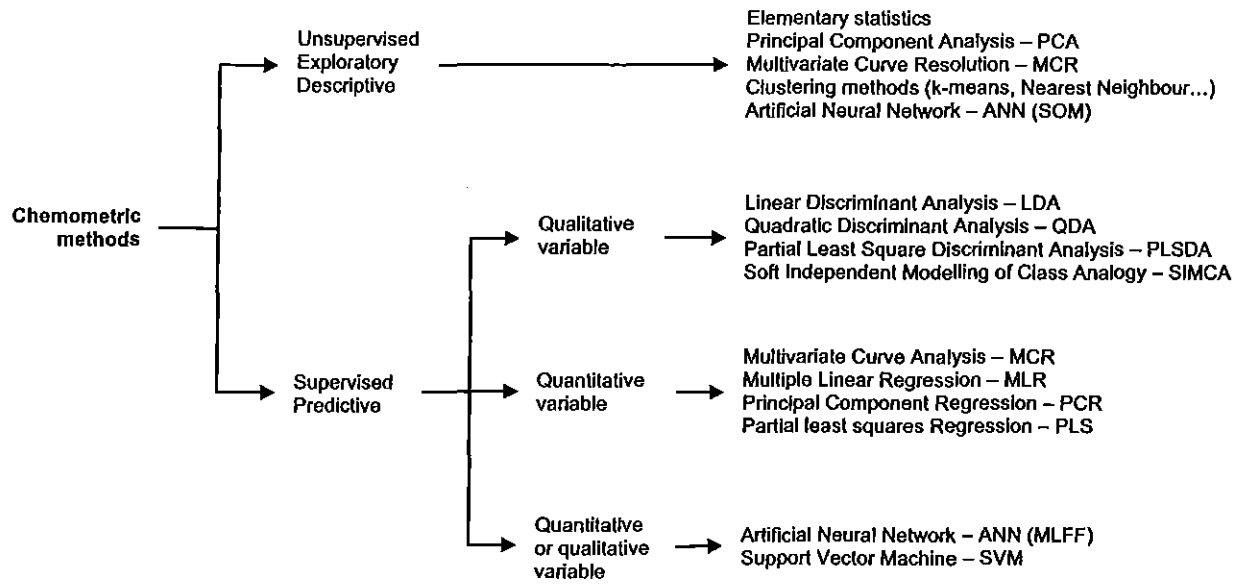

Figure 5.21.-2. – *Map of chemometric methods discussed in the chapter*

1-3-3-2 Quantitative models

The following parameters should be addressed unless otherwise justified: specificity, linearity, range, accuracy, precision and robustness.

Specificity

It is important to detect that the sample that is quantified is not an outlier with respect to the calibration space. This can be done using the correlation coefficient between the sample and the calibration mean, as well as Hotelling T^2 among others.

Linearity

Linearity should be validated by correlating results from the chemometric model with those from an analytical reference method. It should cover the entire range of the method and should involve a specifically selected set of samples that is not part of the calibration set. For orientation purposes, a 'leave-subset-out' cross-validation based on the calibration set may be sufficient, but should not replace assessment using an independent test set. Linearity can be evaluated through the correlation coefficient, slope and intercept of predicted values versus reference values.

Range

The range of analyte reference values defines the range of the chemometric model, and its lower limit determines the limits of detection and quantification of the analytical method. Controls must be in place to ensure that results outside this range are recognised as such and identified. Within the range of the model, acceptance criteria for accuracy and precision have to be fulfilled.

Accuracy

The accuracy of the chemometric model can be determined by comparison of analytical results obtained from the chemometric model with those obtained using a reference method. The evaluation of accuracy should be carried out over the defined range of the chemometric model using an independent test set. It may also be helpful to assess the accuracy of the model using a 'leave-subset-out' cross-validation, although, this should not replace assessment using an independent test set. Accuracy can be evaluated through the slope and intercept of predicted values versus reference values.

Precision

The precision of the analytical method should be validated by assessing the standard deviation of the measurements performed through the chemometric model. Precision covers repeatability (replicate measurements of the same sample by the same person on the same day) and intermediate precision (replicate measurements of the same sample by another person on different days). Precision should be assessed at different analyte values covering the range of the chemometric model, or at least at a target value.

Robustness

For validation of robustness, the same principles as described for qualitative methods apply. Extra care should be taken to investigate the effects of any parameters relevant for robustness on the accuracy and precision of the chemometric model. It can be an advantage to evaluate these parameters using experimental design.

The chemometric model can also be investigated using challenge samples, which may be samples with analyte concentrations outside the range of the method or samples of different identity. During the validation, it must be shown that these samples are clearly recognised as outliers.

2 CHEMOMETRIC TECHNIQUES

A non-exhaustive selection of chemometric methods are discussed below. A map of the selected methods is given in Figure 5.21.-2.

2-1 PRINCIPAL COMPONENTS ANALYSIS

2-1-1 Introduction

The complexity of large data sets or tables makes human interpretation difficult without supplementary methods to aid in the process. Principal components analysis (PCA) is a projection method used to visualise the main variation in the data. PCA can show in what respect 1 sample differs from another, which variables contribute most to this difference and whether these variables contribute in the same way and are correlated or are independent of each other. It also reveals sample set patterns or groupings within the data set. In addition, PCA can be used to estimate the amount of useful information contained in the data table, as opposed to noise or meaningless variations.

2-1-2 Principle

PCA is a linear data projection method that compresses data by decomposing it to so-called latent variables.

The procedure yields columns of orthogonal vectors (scores), and rows of orthonormal vectors (loadings). The principal components (PCs), or latent variables, are a linear combination of the original variable axes. Individual latent variables can be interpreted via their connection to the original variables. In essence, the same data is shown but in a new coordinate system. The relationships between samples are revealed by their projections (scores) on the PCs. Similar samples group together in respect to PCs. The distance between samples is a measure of similarity/dissimilarity.

The original data table is transformed into a new, rearranged matrix whose structure reveals the relationships between rows and columns that may be hidden in the original matrix (Figure 5.21.-3). The new structure constitutes the explained part of the original data. The procedure models the original data down to a residual error, which is considered the unexplained part of the data and is minimised during the decomposition step.

The underlying idea is to replace a complex data table with a simpler counterpart version having fewer dimensions, but still fitting the original data closely enough to be considered a good approximation (Figure 5.21.-4). Extraction of information from a data table consists of exploring variations between samples, i.e. finding out what makes a sample different from or similar to another. Two samples can be described as similar if they have similar values for most variables. From a geometric perspective, the combination of measurements for 1 sample defines a point in a multidimensional space with as many dimensions as there are variables. In the case of close coordinates the 2 points are located in the same area or volume. With PCA, the number of dimensions can be reduced while keeping similar samples close to each other and dissimilar samples further apart in the same way as in the multidimensional space, but compressed into an alternate lower dimensional coordinate system.

The principle of PCA is to find the directions in the data space that describe the largest variation of the data set, i.e. where the data points are furthest apart. Each direction is a linear combination of the initial variables that contribute most to the actual variation between samples.

By construction, principal components (PCs) are orthogonal to each other and are also ranked so that each carries more information than any of those that follow. Priority is therefore given to the interpretation of these PCs, starting with the 1st, which incorporates the greatest variation and thereby constitutes an alternative less complex system that is more suitable for interpreting the data structure. Normally, only the 1st PCs contain pertinent information, with later PCs being more likely to describe noise. In practice, a specific criterion is used to ensure that noise is not mistaken for information and this criterion should be used in conjunction with a method such as cross-validation or evaluation of loadings in order to determine the number of PCs to be used for the analysis. The relationships between samples can then be subsequently viewed in 1 or a series of score plots.

Residuals $\hat{E}$ keep the variation that is not included in the model, as a measure of how well samples or variables fit that model. If all PCs were retained, there would be no approximation at all and the gain in simplicity would consist only of ordering the variation of the PCs themselves by size. Deciding on the number of components to retain in a PCA model is a compromise between simplicity, robustness and goodness of fit/performance.

2-1-3 Assessment of model

Total explained variance R^2 is a measure of how much of the original variation in the data is described by the model. It expresses the proportion of structure found in the data by the model. Total residual and explained variances show how well the model fits the data. Models with small total residual variance (close to 0 per cent) or large total explained variance (close to 100 per cent) can explain most of the variation in the data. With simple models consisting of only a few components, residual variance falls to 0; otherwise, it usually means that the data contains a large amount of noise. Alternatively, it can also mean that the data structure is too complex to be explained using only a few components. Variables with small residual variance and large explained variance for a particular component are well defined by the model. Variables with large residual variance for all or the 1st components have a small or moderate relationship with other variables. If some variables have much larger residual variance than others for all or the 1st components, they may be excluded in a new calculation and this may produce a model that is more suitable for its purpose. Independent test set variance is determined by testing the model using data that was not used in the actual building of the model itself.

2-1-4 Critical aspects

PCA catches the main variation within a data set. Thus comparatively smaller variations may not be distinguished.

2-1-5 Potential use

PCA is an unsupervised method, making it a useful tool for exploratory data analysis. It can be used for visualisation, data compression, checking groups and trends in the data, detecting outliers, etc.

For exploratory data analysis, PCA modelling can be applied to the entire data table once. However, for a more detailed overview of where a new variation occurs, evolving factor analysis (EFA) can be used and, in this case, PCA is applied in an expanding or fixed window, where it is possible to identify, for example, the manifestation of a new component from a series of consecutive samples.

PCA also forms the basis for classification techniques such as SIMCA and regression methods such as PCR. The property of PCA to capture the largest variations in the 1st principal components allows subsequent regression to be based on fewer latent variables. Examples of utilising components as independent data in regression are PCR, MCR, and ANN.

PCA is used in multivariate statistical process control (MSPC) to combine all available data into a single trace and to apply a signature for each unit operation or even an entire manufacturing process based on, for example, Hotelling T^2 statistics, PCA model residuals or individual scores.

In addition to univariate control charts, 1 significant advantage with PCA is that it can be used to detect multivariate outliers, i.e. process conditions or process output that has a different correlation structure than the one present in the previously modelled data.

2-2 MEASURES BETWEEN OBJECTS

The primary use of the following algorithms is to measure the degree of similarity between an object and a group or the centre of the data.

2-2-1 Similarity measures

Calculation of the correlation is the simplest statistical tool used to compare data and to determine the degree of similarity, provided the data sets have the same dimension, e.g. spectral data. It is a measure of the linear association between a pair of vectors. A correlation score between -1 and +1 is calculated for the match, based on the system below,

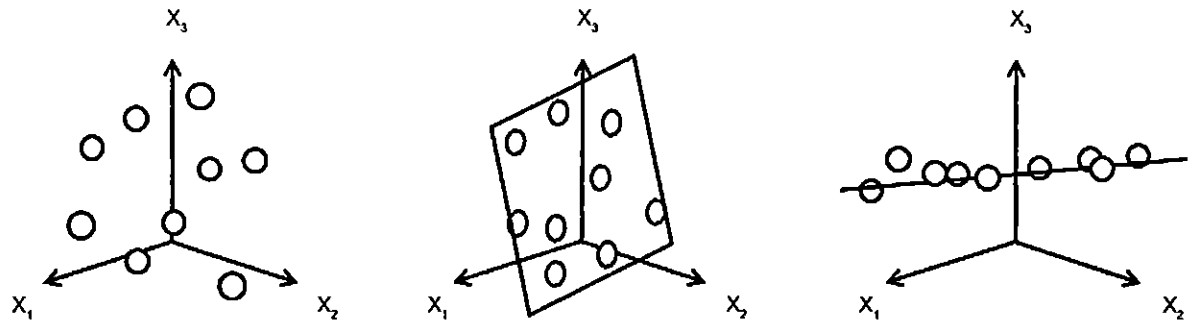

Figure 5.21.-3. – *Geometrical representation of 3 different X-data sets. On the left, objects are plotted in the multivariate space, and the following examples reveal a hidden structure, i.e. a plane and a line respectively*

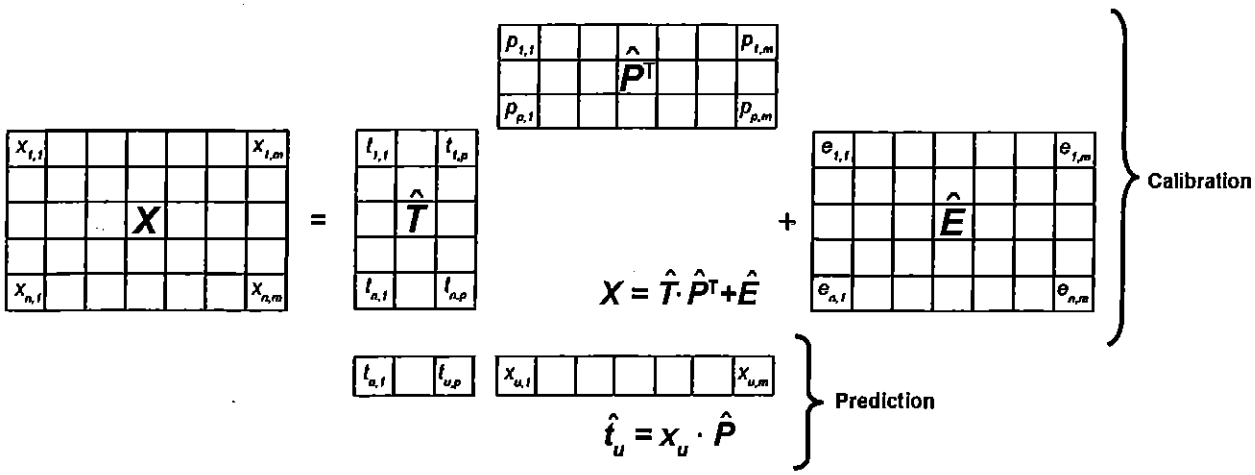

$\hat{X}$ = original data matrix of n rows and m columns
$\hat{T}$ = score matrix with n rows and p columns
$\hat{P}^T$ = loadings matrix with p rows and m columns
$\hat{E}$ = residual matrix (same size as matrix X)
m = number of data points (variables)
n = number of measurements (samples)
p = number of factors
x_u = data of unknown sample
$\hat{t}_u$ = score values for unknown sample

Figure 5.21.-4. – *Decomposition of the X-matrix for principal components analysis (PCA)*

where a perfect match (mirror image) would have a score of +1 and 2 lines that are complete opposites would have a score of -1 (Figure 5.21.-5).

Correlation is used to compare data sets in any of the following ways:

— comparison of 2 selected samples;
— comparison of 1 or more selected samples represented by vectors with a reference data library (from a group or class).

The reference data can be the average of a group of typical characteristics.

Correlation r between 2 mean centred vectors x and y of the same dimension can be calculated using the following equation:

$$r = \frac{\Sigma_i x_i y_i}{\sqrt{\Sigma_i x_i^2 \Sigma_i y_i^2}}$$

2-2-2 Distance measures

In the object space, a collection of objects will be seen as points that are more or less close to each other and will gather into groups or clusters. Measuring the distance between points will express the degree of similarity between objects. In the same way, measuring the distance of a point to the centre of a group will give information about the group membership of this object. The following algorithms are given to illustrate the way objects can be compared.

2-2-2-1 Euclidean distance

The Euclidean distance $ed_{i,j}$ between 2 points i and j can be calculated as:

$$ed_{i,j} = \sqrt{\sum_{k=1}^{m} (x_{i,k} - x_{j,k})^2}$$

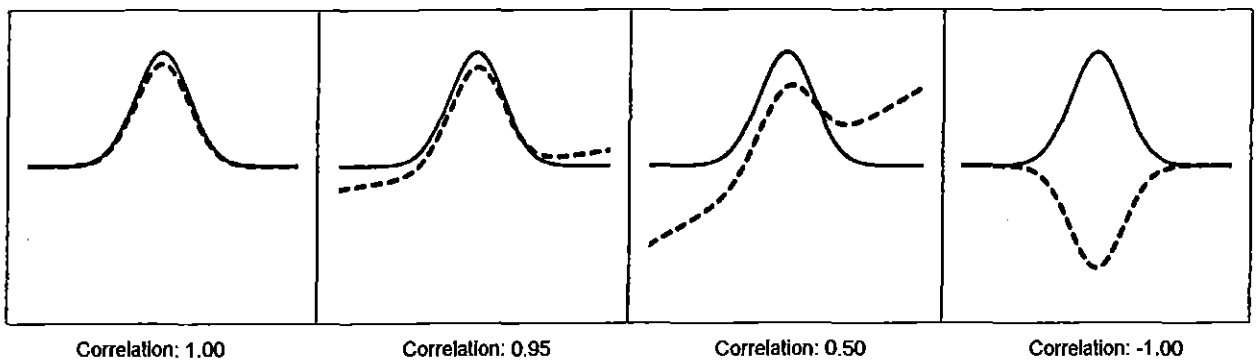

Figure 5.21.-5. – *Examples of correlation scores illustrated by matching of the shapes*

Similarly, the Euclidean distance $ed_{i,c}$ between the point i and the centre c of the data can be calculated as the square root of the sum of the squared differences of the coordinates of point i to the mean value of the x-coordinates for each of the m axes, which can be expressed by the following matrix notation:

$$ed_{i,c} = \sqrt{(x_i - \bar{x})(x_i - \bar{x})^T}$$

where x_i denotes the m values of coordinates describing the point i and $\bar{x}$ denotes the mean coordinates calculated for the m variables. The superscript T indicates that the 2nd term of the equation is transposed.

2-2-2-2 Mahalanobis distance

The Mahalanobis distance (*md*) takes into account the correlation between variables by using the inverse of the variance-covariance matrix.

The variance-covariance matrix C_x is calculated using the following equation:

$$C_x = (1/(n-1))X_C^T X_C$$

where X_c is the $n \times m$ data matrix centred over the mean of each column. Thus C_x is a square matrix that contains the variance of each variable over its diagonal and the covariance between variables on both sides of the diagonal.

The Mahalanobis distance of point i to the centre c of the data is given by the following equation:

$$md_{i,c} = \sqrt{(x_i - \bar{x})C_x{}^{-1}(x_i - \bar{x})^T}$$

The C_x^{-1} matrix is the inverse of the variance-covariance matrix and $C_x C_x^{-1} = I$, where I is the identity matrix.

The number of variables or principal components involved in calculating the distance is designated p, and n is the number of objects in the group or in the data set. Under the assumption that the data is normally distributed, the random variable $(n\text{-}1)^2/n \times md^2$ is beta distributed with degrees of freedom $u = p/2$ and $v = (n\text{-}p\text{-}1)/2$. Thus, if for a point x_i this expression exceeds the (1 - α)-quantile of the beta distribution then the point can be classified as an outlier with the significance level α (i.e. α is the probability of the type-I error classifying the point as an outlier although it is not).

In the same way, the leverage effect (h) of a data point located at the extremity of the X-space on the regression parameters of a multivariate model can be calculated using the following equation:

$$h = \frac{1}{n} + \frac{(md_{i,c})^2}{(n-1)}$$

Data points with high leverage have a large influence on the model.

2-2-2-3 Critical aspects

Euclidean distances only express the similarities or differences between data points when the variables are strictly uncorrelated. If correlations between variables exist they contain at least partially the same information and the dimensionality of data space is in fact smaller than the number of variables. Mahalanobis distances allow for the correction of correlations but their calculation supposes the variance-covariance matrix to be invertible. In some instances where there is high collinearity in the data set, this matrix is singular and cannot be inverted. This is especially the case with spectroscopic data where the high resolution of spectrometers introduces redundancy by essentially describing the same signal through measurements at several consecutive wavelengths. Another constraint in variance-covariance matrix inversion is that the number of variables has to be smaller than the number of objects ($n > m$).

Distances can be computed in the PC space, thus providing the benefits of reduced dimensionality, orthogonality between PCs and also PC ordering. As the 1st PCs carry the maximum amount of information, data reduction without loss of information can be achieved by eliminating the later insignificant PCs.

If a sufficient number of PCs are used to closely model the data, the Euclidean distance of data points to the centre of the data set will be identical when calculated from PC scores and from the coordinates on the original variables. This can be understood by considering that PCA calculation does not transform data but only extracts latent variables to describe the data space without distorting it. The same applies when using Mahalanobis distances, where the values are identical whether the original data space or that of the PCs is used. The only difference is the simplification of the calculation of Mahalanobis distances. Due to the orthogonality between PCs, Mahalanobis distances can be computed as the Euclidean distances calculated over the range of the normalised scores using the multiplication factor $\sqrt{n-1}$.

2-2-3 Linear and quadratic discriminant analysis

2-2-3-1 Principle

In Linear Discriminant Analysis and Quadratic Discriminant Analysis (LDA, QDA), the assignment of a test object x_i to

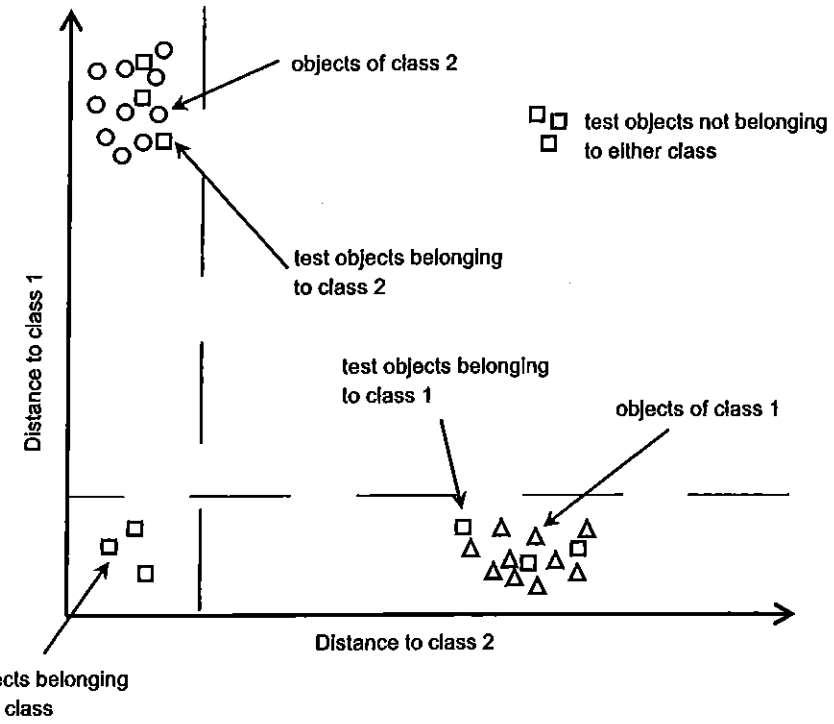

Figure 5.21.-6. – *Plot representing the 4 possible classifications of test objects in a two-class SIMCA analysis (□ = unknown sample to classify, Δ = class 1 sample, ○ = class 2 sample)*

one of K predefined groups (or classes) identified in the data set is determined by the classification score, which is given in the following equation for LDA:

$$cf(x_{i,K}) = (x_i - \bar{x}_K)^T C^{-1}(x_i - \bar{x}_K) + \ln|C| - 2\ln(\pi_K)$$

where π_K is the prior probability of group K and is equal to the number of objects contained in group K divided by the total number of objects in the training set. C is the variance-covariance matrix and $|C|$ is its determinant.

2-2-3-2 Critical aspects

LDA assumes that the variance-covariance matrix for all classes is identical, while QDA estimates a variance-covariance matrix for each class. Hence in QDA far more parameters need to be estimated which should only be done if sufficient data are available.

2-2-3-3 Potential use

It can be used in the case of straightforward classification schemes.

2-3 SOFT INDEPENDENT MODELLING OF CLASS ANALOGY

2-3-1 Introduction

Soft independent modelling of class analogy (SIMCA) is a method for supervised classification of data. The method requires a training set, which consists of samples with known attributes that have been pre-assigned to different classes. SIMCA classes can be overlapping and share common elements. Therefore, a sample can belong to 1, multiple or none of the classes.

2-3-2 Principle

PCA models are 1st established for individual classes. The samples of the training set have to be analysed by PCA (see the section on PCA) and for each class a distinct principal components model is generated. The number of relevant principal components can be adjusted for each class of objects separately. According to this procedure the data sets of each class can be reduced to the relevant principal components models.

New objects are then classified based on the individual PCA models. A new object is projected into each of these models and assigned to a certain class when its residual distance from this model is below the limit for this class (Figure 5.21.-6). Distances of objects to the respective classes can be calculated by procedures such as either Euclidean or Mahalanobis distance. Consequently an object may belong to either 1 or multiple classes if the corresponding distances are within the required threshold. If the distance of an object to all of the SIMCA classes is above the threshold, then it will be classified as an outlier.

2-3-3 Critical aspects

Since SIMCA is mainly based on PCA principles, the validation of the method should follow that of PCA.

In addition to this, the overlap of different classes must also be taken into account. For example, a molecule can have several chemical groups that appear in its spectroscopic profile. Thus, grouping such data into chemical subgroups results in overlap since separation is not possible.

2-3-4 Potential use

SIMCA is often used for the classification of analytical data from techniques such as near-infrared (NIR) or mass spectroscopy, and other analytical techniques such as chromatography and chemical imaging. SIMCA is more suitable than PCA for discriminating between classes that are difficult to separate.

2-4 CLUSTERING

2-4-1 Introduction

A cluster consists of a group of objects or data points similar to each other. Clustering tools can be used to visualise how

data points 'self-organise' into distinct groups or to highlight the degree of similarity between data objects. Data points from a particular cluster share some common characteristics that differentiate them from those gathered in other clusters. Clusters are characterised using 3 main properties; size, shape and distance to the nearest cluster. Clustering is an unsupervised method of data analysis and is used either for explanatory or confirmatory analysis. It differs from discriminant analysis, which is a supervised classification technique, where an unlabelled object is assigned to a group of pre-classified objects.

2-4-2 Principle

Numerous data clustering approaches are available and are typically classed as either hierarchical or non-hierarchical. Hierarchical clustering leads to the classical dendrogram graphical representation of the data, whereas non-hierarchical clustering finds clusters without imposing a hierarchical structure. Numerous algorithms are described in the literature, where data is partitioned either in a specific way or by optimising a particular clustering criterion. This simple and exclusive distinction is incomplete since mixed algorithms have similarities to both approaches. Hierarchical clustering recursively finds clusters either in agglomerative (bottom-up) or divisive (top-down) mode to form a tree shaped structure. Agglomerative mode starts with defining each data point as its own cluster and then merging similar clusters in pairs before repeating this step until the complete data set is classified (Figure 5.21.-7). Divisive mode starts by considering the entire data set as a single cluster, which is then recursively divided until only clusters containing a unique data point are obtained. Algorithms differ in the way they calculate the similarity between clusters. Complete link and single link algorithms calculate the distance between all pairs of objects that belong to different clusters in order to evaluate the similarity between them. In the single link method, this distance corresponds to the minimum distance separating 2 objects originating from 2 different clusters whereas in complete link algorithm this distance corresponds to the largest distance between 2 objects from 2 different clusters. Ward's algorithm, also called the minimum variance algorithm, calculates the similarity between clusters by means of decreasing cluster variance when the 2 most similar clusters are merged.

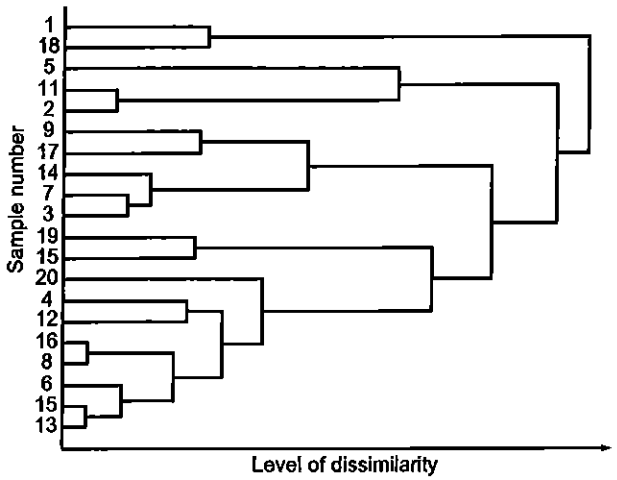

Figure 5.21.-7. – *Dendrogram for agglomerative hierarchical clustering until clusters containing a unique data point are obtained*

Non-hierarchical clustering cannot be described and categorised as easily as hierarchical clustering. Different algorithms exist, which give rise to different classification schemes. An overview of the different categories of algorithms is given below ranging from simple distance based methods such as the minimum spanning tree and the nearest neighbour algorithms, to more sophisticated methods such as the *K*-means algorithm (often cited as a classical partition method), the expectation-maximisation algorithm (for 'model-based' methods) and DBSCAN for 'density-based' algorithms and, also, the 'grid-based' methods which are exemplified by the statistical information grid (STING) algorithm.

Minimum spanning tree clustering, such as Kruskal's algorithm, is similar to the graph theory algorithm as all the data points are first of all connected by drawing a line between the closest points. When all data points are linked, the lines of largest length are broken, leaving clusters of closely connected points. For nearest neighbour clustering, an iterative procedure is used to assign a data point to a cluster when the distance between this point and its immediate neighbour (that belongs to a cluster) is below a pre-defined threshold value.

The *K*-means algorithm is one of the most popular and as with partition algorithms, the number of clusters must be chosen *a priori*, together with the initial position of the cluster centres. A squared error criterion measures the sum of the squared distance between each object and the centroid of its corresponding cluster. The *K*-means algorithm starts with a random initial partition and progresses by reassigning objects to clusters until the desired criteria reach a minimum. Some variants of the *K*-means algorithm allow the splitting or merging of clusters in order to find the optimum number of clusters, even when starting from an arbitrary initial clustering. Model-based clustering attempts to find the best fit for the data using a preconceived model. An example of this is the EM or expectation-maximisation algorithm, which assigns each object to a particular cluster according to the probability of membership for that object. In the EM algorithm, the probability function is a multivariate Gaussian distribution and that is iteratively adjusted to data by use of the maximum-likelihood estimation. The EM algorithm is considered as an extension of the *K*-means algorithm since the residual sum of squares used for *K*-means convergence is similar to the maximum-likelihood criterion.

Density-based (DB) clustering, such as the DBSCAN algorithm, assimilates clusters to regions of high density separated by regions of low or no density.
The neighbourhood of each object is examined to determine the number of other objects that fit within a specified radius and a cluster is defined when a sufficient number of objects inhabit this neighbourhood.

Grid-based algorithms, such as STING, divide the data space into a finite number of cells. The distribution of objects within each cell is then computed in terms of mean, variance, minimum, maximum and type of distribution. There are several levels of cells, providing different levels of resolution and each cell of a particular level corresponds to the union of 4 child cells from the lower level.

2-4-3 Critical aspects

Algorithms are sensitive to the starting conditions used to initialise the clustering of data. For example, *K*-means needs a pre-set number of clusters and the resultant partitioning will vary according to the chosen number of clusters.
The metrics used in distance calculation will also influence

data clustering. For Euclidean distances, the *K*-means algorithm will define spherical clusters whereas they could be ellipsoidal when using Mahalanobis distances. The cluster shape can be modified by data pre-treatments prior to cluster analysis. DB algorithms can deal with arbitrarily shaped clusters, but their weakness is their limitation in handling high-dimensional data, where objects are sparsely distributed among dimensions.

When an object is considered to belong to a cluster with a certain probability, algorithms such as density based clustering, allow a soft or fuzzy clustering. In this case, the border region of 2 adjacent clusters can house some objects belonging to both clusters.

2-4-4 Potential use

Clustering is an exploratory method of analysis that helps in the understanding of data structure by grouping objects that share the same characteristics and in addition, hierarchical clustering allows for classification within data objects. Clustering is used in a vast variety of fields, in particular for information retrieval from large databases. For the latter, the term 'data mining' is frequently used, where the objective is to extract hidden and unexploited information from a large volume of raw data in search of associations, trends and relationships between variables.

2-5 MULTIVARIATE CURVE RESOLUTION

2-5-1 Introduction

Multivariate curve resolution (MCR) is related to principal components analysis (PCA) but, where PCA looks for directions that represent maximum variance and are mutually orthogonal, MCR strives to find contribution profiles (i.e. MCR scores) and pure component profiles (i.e. MCR loadings). MCR is also known as self-modelling curve resolution (SMCR) or end-member extraction. When optimising MCR parameters the alternating least squares (ALS) algorithm is commonly used.

2-5-2 Principle

MCR-ALS estimates the contribution profiles C and the pure component profiles S from the data matrix X, i.e. $X = C \cdot S^T + E$ just as in classical least squares (CLS). The difference between CLS and ALS is that ALS is an iterative procedure that can incorporate information that is known about the physico-chemical system studied and use this information to constrain the components/factors. For example, neither contribution nor absorbance can be negative by definition. This fact can be used to extract pure component profiles and contributions from a well-behaved data set. There are also other types of constraints that may be used, such as equality, unimodality, closure and mass balance.

It is often possible to obtain an accurate estimation of the pure component spectra or the contribution profiles and these estimates can then be used as initial values in the constrained ALS optimisation. New estimates of the profile matrix S and of the contribution profile C are obtained during each iteration. In addition, the physical and chemical knowledge of the system can be used to verify the result, and the resolved pure component contribution profiles should be explainable using existing knowledge. If the MCR results do not match the known system information, then other constraints may be needed.

2-5-3 Critical aspects

Selection of the correct number of components for the ALS calculations is important for a robust solution and a good estimate can be obtained using for example, evolving factor analysis (EFA) or fixed-size moving window EFA.

Furthermore, the constraints can be set as either 'hard' or 'soft', where hard constraints are strictly enforced while soft constraints leave room for deviations from the restricted value. Generally, due to inherent ambiguities in the solution obtained, the MCR scores will need to be translated into, for example, the concentration of the active pharmaceutical ingredient, using a simple linear regression step. This means that the actual content must be known for at least 1 sample. When variations of 2 or more chemical entities are in some way correlated, rank deficiency occurs, for example 1 entity is formed while the other is consumed, or 2 entities are consumed at the same rate to yield a third. As a result, the variation of the individual substance is essentially masked and in such cases, simultaneous analysis of data from independent experiments using varied conditions or combined measurements from 2 measurement techniques generally results in better strategies than analysing the experiments separately one by one.

2-5-4 Potential use

MCR can be applied when the analytical method produces multivariate data for which the response is either linear or can be linearised. This has the advantage that only 1 standard is needed per analyte, which is particularly beneficial when the measurements are at least partly selective between analytes. When linearity and selectivity is an issue, more standards per analyte may be required for calibration. When there is no pure analytical response for an analyte, it is also possible to estimate starting vectors by applying PCA to analyte mixtures together alongside varimax rotation of the PCA coordinate system. ALS implementations of MCR may also allow analyte profiles that are freely varied by the algorithm, which can then be used to model a profile that is difficult to estimate separately, for example a baseline.

2-6 MULTIPLE LINEAR REGRESSION

2-6-1 Introduction

Multiple Linear Regression (MLR) is a classical multivariate method that uses a combined set of x-vectors (X-data matrix) in linear combinations that are fitted as closely as possible to the corresponding single y-vector.

MLR extends linear regression to more than 1 selected variable in order to perform a calibration using least squares fit.

2-6-2 Principle

In MLR, a direct least squares regression is performed between the X- and the Y-data. For the sake of simplicity, the regression of only 1 column vector y will be addressed here, but the method can be readily extended to a Y-matrix, as is common when MLR is applied to data from experimental design (DoE), with multiple responses. In this case, single independent MLR models for each y-variable can be applied to the same X-matrix.

The following MLR model equation is an extension of the normal univariate straight line equation; it may also contain cross and square terms:

$$y = b_0 + b_1 x_1 + b_2 x_2 + \ldots + b_k x_k + f$$

This can be compressed into the convenient matrix form:

$$y = Xb + f$$

The objective is to find the vector of regression coefficients b that best minimises the error term f. This is where the least squares criterion is applied to the squared error terms, i.e. to find b-values so that y-residuals f are minimised.

MLR estimates the model coefficients using the following equation:

$$b = (X^T X)^{-1} X^T y$$

This operation involves the matrix inversion of the matrix $(X^T X)^{-1}$. If any of the X-variables show any collinearity with each other i.e. if the variables are not linearly independent, then the MLR solution will not be robust or a solution may not even be possible.

2-6-3 Critical aspects

MLR requires independent variables in order to adequately explain the data set, but as pharmaceutical samples are comprised of a complex matrix in which components interact to various degrees, the selection of appropriate variables is not straightforward. For example, in ultra-violet spectroscopy, observed absorbance values are linked because they may describe related behaviours in the spectroscopic data set. When observing the spectra of mixtures, collinearity is commonly found among the wavelengths, and consequently, MLR will struggle to perform a usable linear calibration.

The ability to vary the x-variables independently of each other is a crucial requirement when using variables as predictors with this method. This is why in DoE the initial design matrix is generated in such a way as to establish this independence (i.e. orthogonality) from the start. MLR has the following constraints and characteristics:

— the number of X-variables must be smaller than the number of samples ($n > m$), otherwise the matrix cannot be inverted;
— in case of collinearity among X-variables, the b-coefficients are not reliable and the model may be unstable;
— MLR tends to over-fit.

To avoid overfitting MLR is often used with variable selection.

The selection of the optimal number of X-variables can be based on their residual variance, but also on the prediction error.

2-6-4 Potential use

MLR is typically suited to simple matrices/data sets, where there is a high degree of specificity and full rank. As matrices become more complex, more suitable methods such as PLS may be required to provide more accurate and/or robust calibration. In these cases, MLR may be used as a screening technique prior to the application of more advanced calibration methodologies.

2-7 PRINCIPAL COMPONENTS REGRESSION

2-7-1 Introduction

Principal components regression (PCR) is an expansion of principal components analysis (PCA) for use in quantitative applications. It is a two-step procedure whereby the calibration matrix X is first of all transformed by PCA into the scores and loadings matrices $\hat{T}$ and $\hat{P}$ respectively. In the following step, the score matrix for the principal components is used as the input for an MLR model to establish the relationship between the X- and the Y-data.

2-7-2 Principle

As in PCA, the calibration matrix is decomposed into scores and loadings matrices in such a way as to minimise the residual matrix E that ideally consists only of random errors, i.e. noise. For quantitative calibration, an additional matrix Y with the reference analytical data of the calibration samples is necessary. As the concentration information is contained in the orthogonal score vectors of the $\hat{T}$-matrix it can be optimally correlated by multiple linear regression using the actual concentrations in the Y-matrix via the matrix $\hat{Q}$ (Figure 5.21.-8), while minimising the entries in the residual matrix F.

2-7-3 Critical aspects

A crucial point in the development of a model is the selection of the optimal number of principal components. In this respect, the plot of the number of principal components versus the residual Y-variance is an extremely useful diagnostic tool when defining the optimal number of PCs, i.e. when the minimum of the residual Y-variance observed during model assessment has been reached. In most cases, additional PCs beyond this point do not improve the prediction performance but the calibration model falls into overfitting.

Despite its value as an important tool when dealing with collinear X-data, the weakness of PCR lies in its independent decomposition of the X and Y matrices. This approach may take into account variations of the X-data that are not necessarily relevant for an optimal regression with the Y-data. Also, Y-correlated information may even get lost in higher order principal components that are neglected in the above-mentioned selection process of the optimal number of PCs.

A stepwise principal component selection (e.g. selection of PC2 instead of PC1) may be useful to improve the performance of the calibration model.

2-7-4 Potential use

PCR is a multivariate technique with many diagnostic tools for the optimisation of the quantitative calibration models and the detection of erroneous measurements.

In spectroscopy for example, PCR provides stable solutions when dealing with the calibration data of either complete spectra or large spectral regions. However, it generally requires more principal components than PLS and in view of the limitations and disadvantages discussed above, PLS regression has become the preferred alternative for quantitative modelling of spectroscopic data.

2-8 PARTIAL LEAST SQUARES REGRESSION

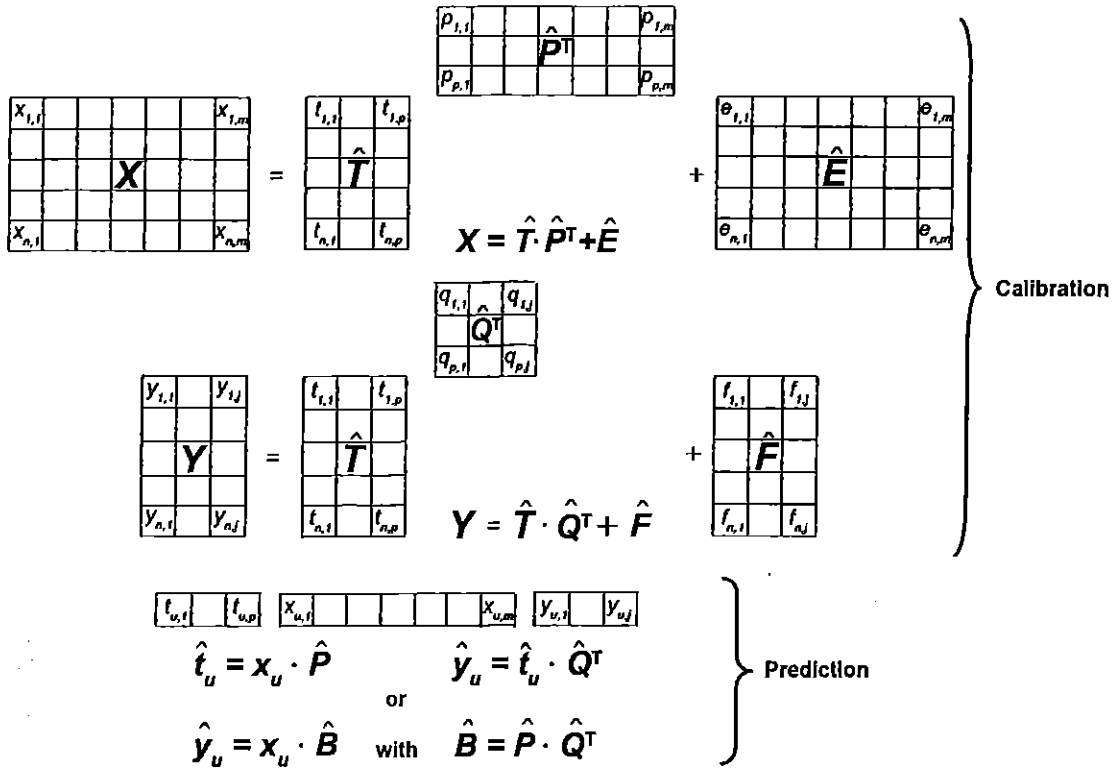
2-8-1 Introduction

Partial least squares regression (PLSR, generally known as PLS and alternatively named projection on latent structures) has developed into the most popular algorithm for multivariate regression.

PLS relates 2 data sets (X and Y) irrespective of collinearity. PLS finds latent variables from X and Y data blocks simultaneously, while maximising the covariance structure between these blocks. In a simple approximation PLS can be viewed as 2 simultaneous PCA analyses applied to the X and Y-data in such a way that the structure of the Y-data is used for the search of the principal components in the X-data. The amount of variance modelled, i.e. the explained part of the data, is maximised for each component. The non-explained part of the data set is made up of residuals, which function as a measure of the modelling quality.

2-8-2 Principle

The major difference between PCR and PLS regression is that the latter is based on the simultaneous decomposition of the X and Y-matrices for the derivation of the components (preferably denoted as PLS factors, factors, or latent-variables). Consequently, for the important factors, the information that describes a maximum variation in X, while correlating as much as possible with Y, is collected. This is



X	=	original data matrix of n rows and m columns	m	=	number of data points (variables)
$\hat{T}$	=	scores matrix with n rows and p columns	n	=	number of measurements (samples)
$\hat{P}^T$	=	loadings matrix with p rows and m columns	j	=	number of property values per sample
$\hat{E}$	=	residual matrix (same size as X-matrix)	p	=	number of principal components (factors)
Y	=	property matrix of n rows and j columns	x_u	=	data of unknown sample
$\hat{Q}^T$	=	correlation matrix of p rows and j columns	$\hat{y}_u$	=	predicted property values of unkown sample
$\hat{F}$	=	residual matrix (same size as Y-matrix)	$\hat{t}_u$	=	score values for unknown sample
$\hat{B}$	=	matrix of regression coefficients			

Figure 5.21.-8. – *Decomposition of the matrices for principal components regression (PCR)*

precisely the information that is most relevant for the prediction of the *Y*-values of unknown samples. In practice PLS can be applied to either 1 *Y*-variable only (PLS1), or to the simultaneous calibration of several *Y*-variables (PLS2 model).

As the detailed PLS algorithms are beyond the scope of this chapter, a simplified overview is instead given (Figure 5.21.-9). Arrows have been included between the $\hat{T}$ and $\hat{U}$ scores matrices in order to symbolise the interaction of their elements in the process of this iteration. While the *Y*-matrix is decomposed into the loadings and scores matrices $\hat{Q}$ and $\hat{U}$ respectively, the decomposition of the *X*-matrix produces not only the loadings and scores matrices $\hat{P}$ and $\hat{T}$, but also a loading weights matrix $\hat{W}$, which represents the relationship between the *X* and *Y*-data.

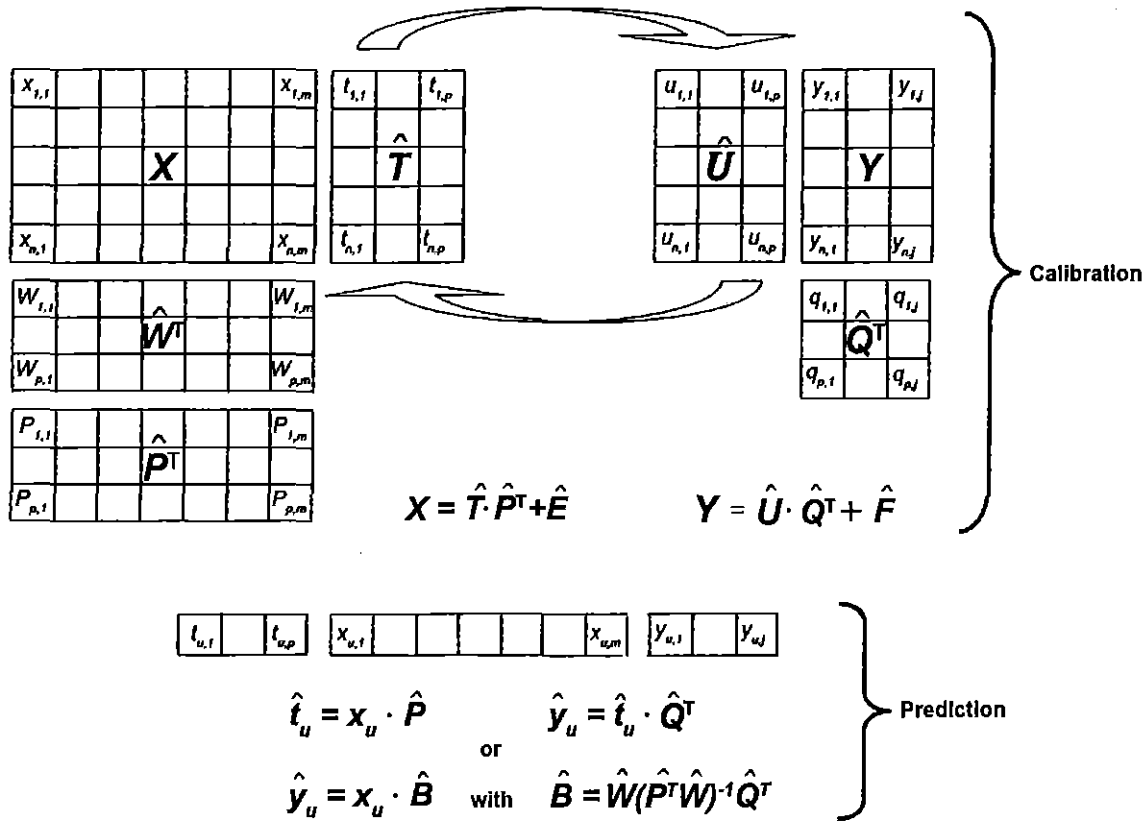
To connect the *Y*-matrix with the *X*-matrix decomposition for the first estimation of the $\hat{T}$ score values, the *Y*-data are used as a guide for the decomposition of the *X*-matrix. By interchanging the score values of the $\hat{U}$ and $\hat{T}$ matrices, an interdependent modelling of the *X* and *Y* data is achieved, thereby reducing the influence of large *X*-variations that do not correlate with *Y*. Furthermore, simpler calibration models with fewer PLS-factors can also be developed where, as is the case for PCR, residual variances are used during validation to determine the optimal number of factors that model useful information and consequently, avoid overfitting.

2-8-3 Critical aspects

A critical step in PLS is the selection of the number of factors. Selecting too few factors will inadequately explain variability in the training data set, while too many factors will cause overfitting and instability in the resulting calibration (Figure 5.21.-10). The optimal number of factors is estimated during validation of the calibration.

Figure 5.21.-10 shows the changes in the calibration error (A) of a model and 2 cases of prediction errors (B, C) according to the number of factors used in the model. The calibration error decreases continuously as the number of factors increases. In case B prediction error reveals that no minimum can be observed; however, a minimum is observed in case C. In the absence of a minimum, the number of components can be chosen based on where no significant decreasing of error is observed.

As far as the decision between PLS1 or PLS2 models is concerned PLS1 modelling is chosen if there is only 1 *Y*-variable of interest. In cases where there is more than 1 *Y*-variable of interest, either one PLS2 model or individual



X = original data matrix of n rows and m columns
Y = property matrix of n rows and j columns
$\hat{T}$ = scores matrix with n rows and p columns
$\hat{P}^T$ = loadings matrix with p rows and m columns
$\hat{W}^T$ = loading weights matrix with p rows and m columns
$\hat{E}$ = residual matrix (same size as X-matrix)
$\hat{Q}^T$ = loadings matrix of Y-data
$\hat{U}$ = scores matrix of Y-data
$\hat{F}$ = residual matrix (same size as Y-matrix)
$\hat{B}$ = matrix of regression coefficients
m = number of data points (variables)
n = number of measurements (samples)
j = number of property values per sample
p = number of factors
x_u = data of unknown sample
$\hat{y}_u$ = predicted property values of unknown sample
$\hat{t}_u$ = score values for unknown sample.

Figure 5.21.-9. – *Decomposition of the data matrices for PLS regression*

PLS1 models for each Y-variable can be calculated. In general, PLS2 is the preferred approach for screening purposes and in cases of highly correlated Y-variables of interest; otherwise separate PLS1 models for the different Y-variables will yield more satisfactory prediction results.

2-8-4 Potential use

PLS has emerged as a preferable alternative to PCR for quantitative calibration because it incorporates the intervention of the Y-data structure for the decomposition of the calibration X-matrix. Consequently, information from the most important factors is collected and is capable of describing maximal variation in the X-data, while also correlating as closely as possible with the Y-data. In general, this yields simpler models with fewer factors compared to PCR and also provides superior interpretation possibilities and visualisation diagnostics for the optimisation of the calibration performance. In addition PLS can handle presence of noise in both X- and Y-data.

PLS discriminant analysis (PLS-DA) is a special case of PLS where X-matrix is regressed into a dummy Y-matrix consisting of ones and zeroes. Ones and zeroes indicate the class to which samples are belonging or not. PLS-DA is used as a semi-quantitative method in, for example, chemical imaging estimating the pixel components.

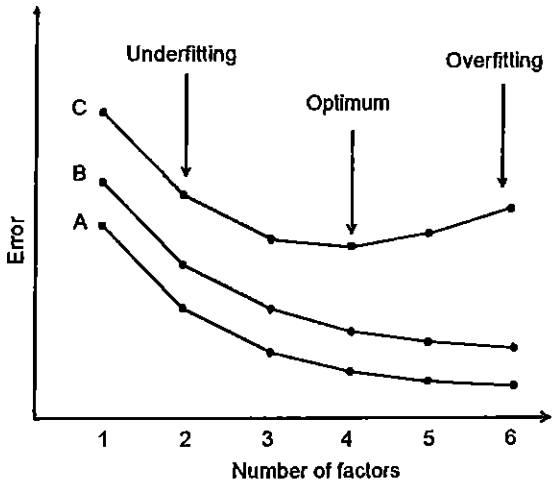


Figure 5.21.-10. – *Effects of adding factors to a model; the calibration becomes more accurate i.e. the residual error diminishes, while the predictive performance of the model could deteriorate as for prediction C. The optimum number of factors reflects a compromise.*

2-9 SUPPORT VECTOR MACHINES

2-9-1 Introduction

To achieve classification, multivariate techniques reduce the dimensionality and complexity of the data set. Kernel methods project data into higher dimensional feature spaces.

2-9-2 Principle

Support vector machines (SVMs) project *X*-data of the training set into a feature space of usually much higher dimension than the original data space. In the feature space a hyperplane (also called decision plane) is computed that separates individual points of known group membership (Figure 5.21.-11). The best discriminating separation is achieved by maximising the margin between groups. The margin is defined by 2 parallel hyperplanes at an equal distance from the decision plane. The optimum position of the decision plane is obtained if the margin is maximal. Points in the feature space that define the margin are called support vectors.

For each training point the distance to the decision plane is computed. In the case of a two-class separation for example, the sign of the distance gives the group membership and the value corresponds to the certainty of classification. During modelling the distance between the training points and the hyperplane contributes to the weight attributed to the point. Very distant points will have a lesser weight, and to avoid overfitting, distances smaller than a trade-off parameter will not be considered.

For non-separable object groups overlapping is allowed to a certain extent. So-called slack variables are added to objects, with value 0 if correctly classified and a positive value otherwise. The optimal hyperplane is found by maximising the margin at the same time allowing for a minimum number of training points to be misclassified (Figure 5.21.-12). The proportion of misclassified points becomes a control parameter during margin maximisation.

In practice SVM computation is extremely complex and would be infeasible without simplifying of the optimisation problem. To project *X*-data into the feature space the original data is expanded by a set of basis functions. Selecting particular basis functions makes it possible to reformulate the whole optimisation procedure. Only products of the expanded variables remain part of the optimisation procedure and they can be advantageously replaced by a Kernel function.

2-9-3 Critical aspects

Numerous algorithms and different types of software can be used to compute SVMs, which may lead to differing results. Optimisation will vary depending on the algorithm used. Control criteria may differ, thus leading either to divergence during the iterations, or to unstable computations sensitive to redundant and uninformative data.

During SVM computation training points that are well inside their class boundaries have little or even no effect on the position of the decision plane. The latter focusses mainly on points that are difficult to separate and not on objects that are clearly distinct. Thus, SVMs are sensitive to redundant values and atypical points like outliers, for example. As a consequence it may be pertinent to select or screen out specific variables prior to performing SVM. The data should be normalised and standardised to avoid having input data of different scales, which may lead to poor conditions for the boundary optimisation.

The best performing model must be adequately validated and test data that is completely untouched during iterations is required for this purpose. It should be ensured that this data is well balanced in the sense that both easy and difficult samples are equally represented in the training and validation sets.

2-9-4 Potential use

SVMs are mainly used for binary supervised classification. They can be generalised to multiclass classification or extended to regression problems, though these applications are not considered within the scope of this chapter. Objects that are difficult to classify rather than those that are clearly distinct drive the optimisation process in SVMs. SVMs can be used for the separation of classes of objects, but not for the identification of these objects. They operate well on large data sets that are obtained, for example, by NIR spectroscopy, magnetic resonance, chemical imaging or process data mining, where PCA and related methods fail. Their strength mainly lies in separation of samples featuring highly correlated signals, i.e. polymorphs, excipients, tracing of adulterated substances, counterfeits etc.

2-10 ARTIFICIAL NEURAL NETWORKS

2-10-1 Introduction

Artificial neural networks (ANNs) are general computational tools, whose initial development was inspired by the need for further understanding of biological neural networks and which have since been widely used in various areas that require data processing with computers or machines. The methods for building ANN models and their subsequent applications can be dramatically different depending on the architecture of the neural networks themselves. In the field of chemometrics, ANNs are generally used for multivariate calibration and unsupervised classification, which is achieved by using multi-layer feed-forward (MLFF) neural networks, or self-organising maps (SOM) respectively. As a multivariate calibration tool, ANNs are more generally associated with the mapping of non-linear relationships.

2-10-2 Principle

2-10-2-1 General

The basic data processing element in an artificial neural network is the artificial neuron, which can be understood as a mathematical function that uses the sum of a weighted vector and a bias as the input. The vector is the 'input' of the neuron and is obtained either directly from a sample in the

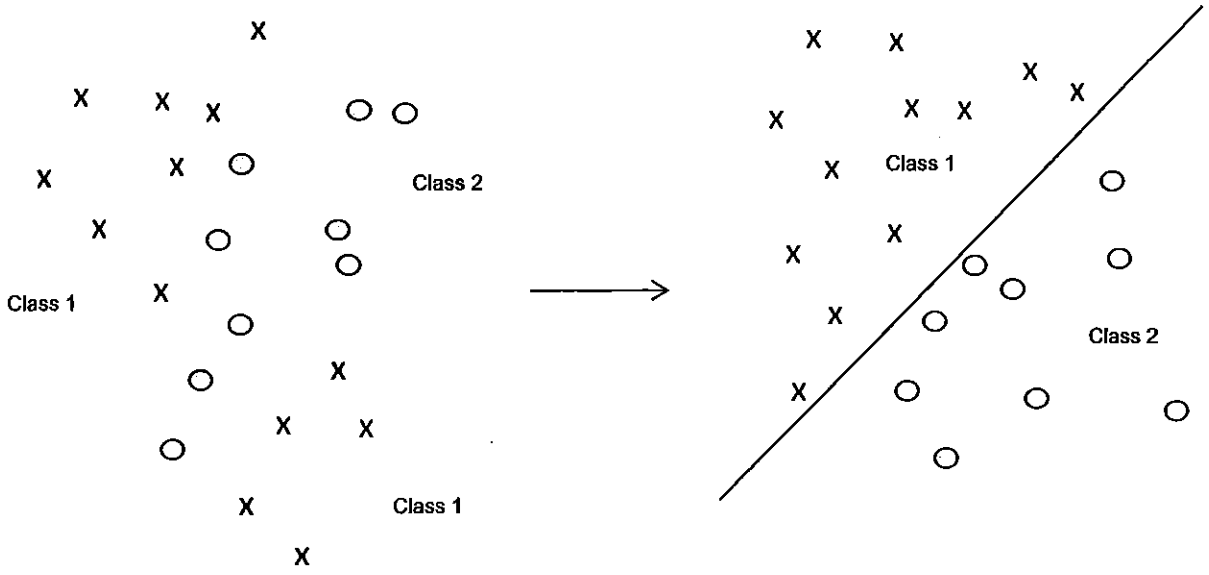

Figure 5.21.-11. – *The object space, where separation of the 2 classes is not possible, is mapped into a feature space where separation is possible*

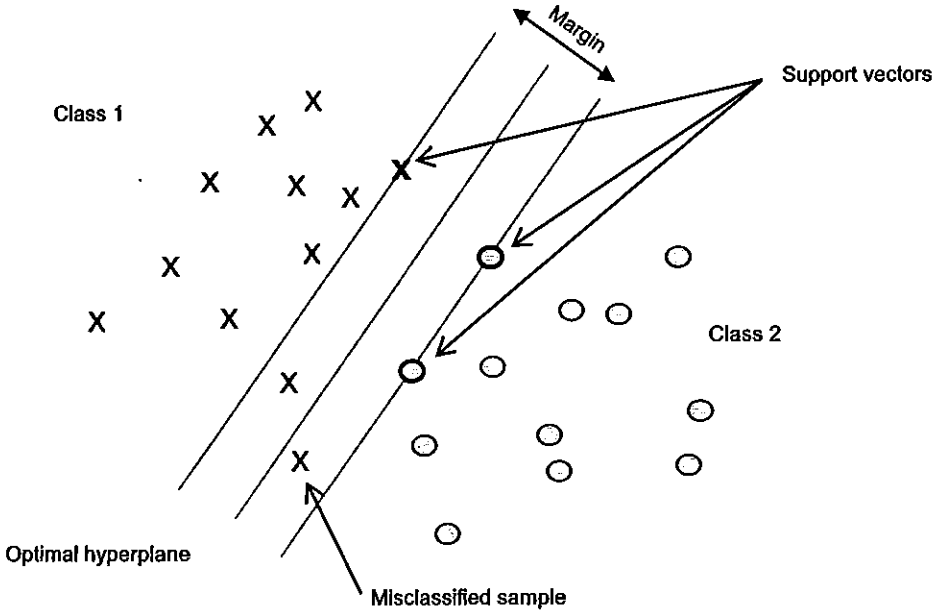

Figure 5.21.-12. – *In the feature space, the separation of classes 1 and 2 was achieved with toleration of certain misclassified samples*

data set or calculated from previous neurons. The user chooses the form of the function (called transfer function). The weights and bias are the coefficients of the ANN model and are determined through a learning process using known examples. An ANN often contains many neurons arranged in layers, where the neurons in each layer are arranged in parallel. They are connected to neurons in the preceding layer from which they receive inputs and also to neurons in the following layer where the outputs are sent (Figure 5.21.-13). The output of 1 neuron is therefore used as the input for neurons in the following layer. The input layer is a special layer that receives data directly from the user and sends this information directly to the next layer without applying a transfer function. The output layer is similar in that its output is also directly used as the model output without any additional processing. The unlimited possibilities when connecting different numbers and layers of neurons, is often called an ANN architecture, and provides the potential for ANNs to meet any complicated data modelling requirements.

2-10-2-2 Multi-layer feed-forward artificial neural network

A multi-layer feed-forward network (MLFF ANN) contains an input layer, an output layer and 1 or more layers of neurons in-between called hidden layers. Even though there is no limit on how many hidden layers may be included, an MLFF ANN with only 1 hidden layer is sufficiently capable of handling most multivariate calibration tasks in chemometrics. In an MLFF ANN, each neuron is fully connected to all the neurons in the neighbouring layers. A hyperbolic tangent sigmoid transfer function is usually used in MLFF ANN, but other transfer functions, including linear functions, can also be used.

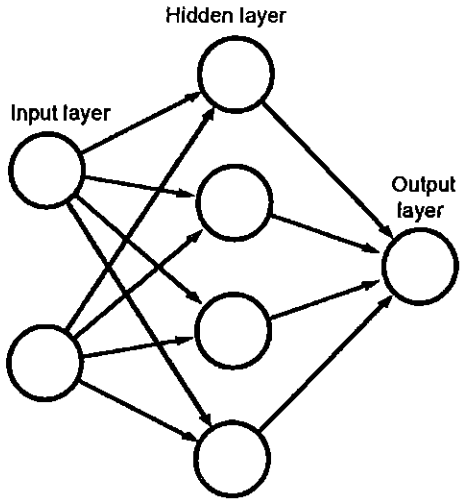

Figure 5.21.-13. - *Typical arrangements of neuron layers and their inter-connections*

The initial weights and biases can be set as small random numbers, but can also be initialised using other algorithms. The most popular training algorithm for determining the final weights and biases is the back-propagation (BP) algorithm or its related variants. In the BP algorithm, the prediction error, calculated as the difference between the ANN output and the actual value, is propagated backward to calculate the changes needed to adjust the weights and biases in order to minimise the prediction error.

An MLFF ANN must be optimised in order to achieve acceptable performance. This often involves a number of considerations including the number of layers, the number of neurons in each layer, transfer functions for each layer or neuron, initialisation of weights, learning rate, etc.

2-10-2-3 Self-organising map

The aim of the self-organising map (SOM) is to create a map where observations that are close to each other have more similar properties than more distant observations.

The neurons in the output layer are usually arranged in a two-dimensional map, where each neuron can be represented as a square or a hexagon. SOMs are trained using competitive learning that is different from the above described method using BP. The final trained SOM is represented as a two-dimensional map of the observations.

2-10-3 Critical aspects

The 2 most common pitfalls of using ANNs are over-training and under-training. Over-training means that an ANN model can predict the training set very well but ultimately fails to make good predictions. Under-training means that the ANN training ended too soon and therefore the resultant ANN model underperforms when making predictions. Both of these pitfalls should be avoided when using ANNs for calibration. A representative data set with a proper size, i.e. more observations or samples than variables, is required before a good ANN model can be trained. Generally, since the models are non-linear, more observations are needed than for a comparable data set subjected to linear modelling. As for other multivariate calibration methods, the input may need pre-processing to balance the relative influence of variables. One advantage of pre-processing is the reduction in the number of degrees of freedom of input to the ANN, for example by compression of the *X*-data to scores by PCA and then using the resulting scores for the observations as input.

2-10-4 Potential use

The advantage of MLFF ANN in multivariate calibration lies in its ability to model non-linear relationships. Since the neurons are fully connected, all the interactions between variables are automatically considered. It has been proven that a MLFF ANN with sufficient hidden neurons can map any complicated relationship between the inputs and outputs.

SOMs can be used to visualise high-dimensional data while preserving the topology in the original data. They are based on unsupervised learning, and are mainly useful as tools to explore features in data sets where no prior knowledge of the patterns and relationships of the samples exists.

The ANNs often have a large number of coefficients (weights and biases) that give the ANN the potential to model any complicated relationships in the data set but as a result, can also make the interpretation of the coefficients more difficult. However, when linear modelling methods are not flexible enough to provide the required prediction or classification accuracy, ANNs may be a good alternative.

3 GLOSSARY

β-distribution

Continuous probability distribution with density function

$$f(x;u,v) = \frac{1}{B(u,v)} x^{u-1}(1-x)^{v-1}$$

where $u > 0$, $v > 0$ are shape parameters (degrees of freedom) and B is the beta function,

$$B(u,v) = \int_0^1 t^{u-1}(1-t)^{v-1}dt$$

The γ-quantile of the $\beta(u,v)$-distribution is denoted by $\beta_{u,v,\gamma}$ and it is the value q such that the value of the distribution function F is γ:

$$F(x;u,v) = \int_0^q f(x;u,v)dx = \gamma$$

Bootstrapping

A number of sample sets of size n that is produced from an original sample set of the same size n by means of a random selection of samples with replacement.

Centring

A data set is mean centred by calculating the mean value of each variable and subtracting the variable mean values from each column of variables, in order to make the comparison and interpretation of the data easier.

Collinear/non-collinear

A family of vectors is collinear if at least 1 of the vectors can be represented as a linear combination of the other vectors. Hence a family of vectors is non-collinear if none of the vectors can be represented as a linear combination of the others.

Component (or factor, latent variable)

In chemometrics: underlying, non-observed, non-measured, hypothetical variable that contributes to the variance of a collection of measured variables. The variables are linear combinations of the factors and these factors are assumed to be uncorrelated with each other.

Data mining

Process of exploration, extraction and modelling of large collections of data in order to discover *a priori* unknown relationships or patterns.

Dependent variable
Also a response, regressand: a variable that is related by a formal (explicit) or empirical mathematical relationship to 1 or more other variables (typically the *Y*-data).

Empirical model
A data-driven model established without assuming an explicit mathematical relationship, or without a description of the behaviour of a system based on accepted laws of physics.

Exploratory data analysis
The process for uncovering unexpected or latent patterns in order to build future hypotheses.

Factor
See component.

Hotelling T^2 statistics
Multivariate version of the t-statistic. In general, this statistic can be used to test if the mean vector of a multivariate data set has a certain value or to compare the means of the variables. The T^2 statistic is also used for detection of outliers in multivariate data sets. A multivariate statistical test using the Hotelling T^2 statistic can be done. A confidence ellipse can be included in score plots to reveal points outside the ellipse as potential outliers.

Independent variable
Input variable on which other variables are dependent through a mathematical relationship (typically the *X*-data).

Indirect prediction
Process for estimating the value of a response on the basis of a multivariate model and observed data.

Interference
Effect of substances, physical phenomena or instrument artefacts, separate from the target analyte, that can be measured by the chosen analytical method. Then there is a risk of confusion between the analyte and interference if the interference is not varied independently or at least randomly in relation to the analyte.

Latent variable
See component.

Leave-one-out
In a 'leave-one-out' procedure only 1 sample at a time is removed from the data set in order to create a new data set.

Leave-subset-out
In a 'leave-subset-out' procedure a subset of samples is removed from the data set in order to create a new data set.

Leverage
A measure of how extreme a data point or a variable is compared to the majority. Points or variables with a high leverage are likely to have a large influence on the model.

Loadings
Loadings are estimated when information carried by several variables is focussed onto a few components. Each variable has a loading alongside each model component. The loadings show how well a variable is taken into account by the model components.

Orthogonal
2 vectors are orthogonal if their scalar product is 0.

Orthonormal vectors
Orthogonal and normalised (unit-length) vectors.

Outlier
For a numerical data set, it relates to a value statistically different from the rest. Also refers to the sample associated with that value. Specific statistical testing for outliers may be used.

Overfitting
For a model, overfitting is a tendency to describe too much of the variation in the data, so that in addition to the consistent underlying structure, some noise or non-informative variation is also taken into account and unreliable predictions will be obtained.

Property
See variable.

Resampling
The process of impartial rearrangement and sub-sampling of the original data set. This occurs during optimisation/validation procedures that repeatedly calculate a property and the error associated with it. Typical examples are cross-validation and bootstrapping, which create successive evaluation data sets by repeated sub-sampling.

Reselection
Reuse of samples (see resampling).

Residuals
A measure of the variation that is not taken into account by the model or a deviation between predicted and reference values.

Root mean square error of prediction
A function of the predictive residual sum of squares to estimate the accuracy:

$$RMSEP = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}}$$

where $\hat{y}_i$ is the predicted response for the i^{th} sample of the test data set and y_i the observed response of the i^{th} sample, and n is the number of samples.

Sample
Object, observation, or individual from which data values are collected.

Sample attribute
Qualitative or quantitative property of the sample.

Sample selection
The process of drawing a subset or a collection from a population in order to estimate the properties of the population.

Scores or factor score coefficients
Coordinates of the samples in the new coordinate system defined by the principal components. Scores represent how samples are related to each other's given the measurement variables.

Score (normalised)
j^{th} score value $t_{i,j}$ of the i^{th} sample divided by the norm of the scores matrix:

$$|t_{i,j}| = \frac{t_{i,j}}{\sqrt{\sum_{j=1}^{p} t_{i,j}^2}}$$

where p is the number of parameters in the model.

Standard error of calibration
A function of the predictive residual sum of squares to estimate the accuracy considering the number of parameters:

$$SEC = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n - p}}$$

where n is the number of samples of the learning set, p the number of parameters in the model to be estimated by using the sample data, $\hat{y}_i$ the i^{th} fitted value in the calibration, and y_i the i^{th} reference value. In multiple regression with m variables $p = m + 1$ (1 coefficient for each of the m variables and 1 intercept).

Standard error of laboratory
Concerns to the intermediate precision or reproducibility, whichever is applicable.

Supervised
Refers to modelling data labelled by classes or values.

Unsupervised (non-supervised)
Refers to exploring data without prior assumptions.

Underfitting
The reverse of overfitting.

Variable
Property of a sample that can be assessed (attribute, descriptor, feature, property, characteristics).

Varimax rotation
Orthogonal analytical rotation of factors that maximises the variance of squared factor loadings, thereby increasing the large factor loadings and large eigenvalues and decreasing the small ones in each factor.

S. Raw Materials of Biological Origin for the Production of Cell-based and Gene Therapy Medicinal Products

(Ph. Eur. general texts 5.2.12)

This general chapter is published for information.

It contains sections on the quality requirements of raw materials used for the production of cell-based and gene therapy medicinal products for human use. The provisions of the chapter do not exclude the use of different production and control methods. It is the responsibility of the manufacturer of a raw material to qualify (prove to be suitable for the intended use) the raw material in accordance with the requirements given in this general chapter.

However, it is ultimately the responsibility of the user of a raw material to ensure it is of suitable quality for the specific use.

The quality of the raw materials may be considered according to the stage of development of the cell-based or gene therapy medicinal product, thereby acknowledging the inherent evolution of the quality profile of the product during its pharmaceutical and clinical development. Nevertheless, patient safety needs to be ensured in early phase clinical development. The aim is to have an appropriate qualification strategy for the raw materials when used for the production of cell-based/gene therapy medicinal products. It should be noted that changes in raw materials during the lifecycle of the cell-based/gene therapy medicinal product may affect the quality of the medicinal product and thus require additional studies to demonstrate comparability.

The impact of the raw material on the quality, safety and efficacy of the cell-based/gene therapy medicinal product is evaluated using a risk-based approach. Raw materials are used in order to consistently yield an active substance or medicinal product of a specified quality in terms of, for example, biological activity, purity/impurity profile, the risk of adventitious agents (bacteria, viruses, etc.) and stability.

From a risk perspective, the use of raw materials free from human or animal substances is preferred.

The biological nature of a raw material used for the production of cell-based/gene therapy medicinal products places special requirements on its quality. Examples of the critical quality attributes specific to each class of raw material are given in this general chapter.

1 SCOPE

This general chapter applies to raw materials of biological origin used for the production of cell-based/gene therapy medicinal products. The raw materials used in the manufacture of active substances are not intended to form part of the active substance. The raw materials can be extracted from various biological sources or produced by recombinant DNA technology.

This general chapter applies to the following classes of raw materials:

- sera and serum replacements;
- proteins produced by recombinant DNA technology such as growth factors, cytokines, hormones, enzymes and monoclonal antibodies;
- proteins extracted from biological material such as enzymes and polyclonal antibodies;
- vectors.

The principles of this general chapter may also be applied to other classes of biological raw materials where appropriate.

Medical devices, plastics and chemically synthesised raw materials, such as basal media (purely composed of chemicals), synthetic peptides or synthetic polynucleotides, are not within the scope of this general chapter.

2 RISK ASSESSMENT

Evaluation of the impact of the raw material on the quality, safety and efficacy of cell-based/gene therapy medicinal products must be performed by the user of the raw material. No single measure or combination of measures can guarantee the quality, functionality and safety of a raw material for its intended use. Therefore, a risk assessment must consider the biological origin and traceability of the raw material, the production steps applied to it and the ability of the drug product manufacturing process to control or remove the raw material from the final medicinal product.

Any risk factor must be evaluated in relation to the clinical benefit/risk of the cell-based or gene therapy medicinal product. When evaluating the risk posed by the raw material to the final medicinal product, the exposure of a patient to residual amounts of raw material with potential harmful effects (e.g. adverse immune reactions) should be considered in relation to the clinical benefit/risk of the cell-based or gene therapy medicinal product.

3 GENERAL REQUIREMENTS

3-1 ORIGIN

The origin of the raw material and if relevant any biological substances used for the production of the raw material must be known. Special attention must be paid to risks related to the sourcing (including pooling) of the substances used for the production of the raw material. Depending on the source of the raw material and the substances used in its production, raw materials can be divided into 3 categories:

1) raw materials of human or animal origin;

2) raw materials produced using substances of human or animal origin;

3) raw materials free from substances of human or animal origin.

Traceability of all raw materials is required, with particular attention to those materials with an inherent safety concern i.e. those of human or animal origin.

Due to the inherent risk of transmitting adventitious agents, it is recommended to minimise, wherever possible, the use of raw materials of human or animal origin. If such raw materials are required for the production of cell-based/gene therapy medicinal products, appropriate measures are taken to minimise the risks of transmitting adventitious agents such as viruses, prions, bacteria and protozoa.

For human blood and tissue-derived materials, only carefully evaluated donors who have been adequately tested for infectious transmissible agents may be used. These materials comply with appropriate EU and/or national legislation applicable to transplantation and transfusion. Traceability measures enable each donation to be followed from the donation to the raw material and to the final product, and vice-versa.

When raw materials of animal origin are used, these animals fulfil specific health requirements and should be fit for human consumption and reared under controlled conditions, when applicable. If the origin of the animals is not fully traceable (e.g. animals collected from the wild), information on their geographic location at the time of sourcing should be considered.

When vectors or proteins produced by recombinant DNA technology are used as raw materials, traceability to the master cell bank/virus seed lot is required.

For all raw materials of human or animal origin, or raw materials produced using substances of human or animal origin, a viral risk assessment is performed according to the requirements of general chapter *5.1.7. Viral safety*. The extent of viral safety testing is dependent on the results of the initial risk assessment. In addition, a risk assessment with respect to transmissible spongiform encephalopathies is carried out and suitable measures are taken to minimise such risks as described in general chapter *5.2.8. Minimising the risk of transmitting animal spongiform encephalopathy agents via human and veterinary medicinal products*.

3-2 PRODUCTION

All raw materials are produced within a suitable quality management system and production facilities.

Suitable in-process controls are in place to ensure that the production process is under control and consistently produces raw materials of defined quality.

Quality attributes for raw materials include identity, purity and biological activity where applicable, and they are to be demonstrated using appropriate, qualified control methods. Relevant specifications in terms of identity, purity/impurity profile and assays are to be established.

The production process is optimised to consistently minimise and/or remove adventitious agents and harmful impurities, whilst retaining the quality of the raw material. This can be achieved using one or a combination of the following measures:

- using validated inactivation/removal procedures such as gamma sterilisation or low pH during chromatography, where possible;
- demonstrating the ability of a production process to minimise, remove or inactivate adventitious agents or harmful impurities;
- testing for adventitious agents or harmful impurities.

A raw material is sterile and produced under aseptic conditions and/or subject to terminal sterilisation, unless otherwise justified. If the raw material is not sterile, the level of microbial contamination must be known.

Additives, such as stabilisers, may be added to the raw material. In cases where antibiotics and stabilisers of biological origin are used in the production of the raw material, their presence is justified and careful consideration is given to their selection, use, quality and concentration in the raw material, as well as their impact on the actual raw material itself.

3-3 GENERAL QUALITY REQUIREMENTS

Raw materials must meet pre-defined quality requirements for identity, purity and biological activity. In order to ensure the function of the raw material, it is subject to testing using appropriately qualified methods. The identity test must reflect the uniqueness of the raw material and distinguish it from other related or similar substances. Impurities include both process-related substances (e.g. in the case of recombinant proteins: host-cell-derived proteins (HCP), host-cell-derived DNA and vector-derived DNA (residual DNA), other biological or chemical substances) and product-related substances (e.g. aggregates and degradation products).

The content of a raw material may be expressed either in absolute or relative terms. The assay for determination of biological activity may be used to establish the content.

3-3-1 IDENTIFICATION

The identity tests are specific for the particular raw material and address the molecular structure/composition or other relevant physico-chemical, biological or immunochemical properties. Methods used in the determination of biological activity and purity may also serve to identify the raw material. Identification may be carried out by comparison with a defined reference material or a representative batch of the raw material.

3-3-2 TESTS

Tests that may be applicable to raw materials include the following (see also the sections below for specific raw materials):

Appearance
Liquid or reconstituted freeze-dried raw materials comply with the limits defined for the particular raw material with regard to degree of opalescence (*2.2.1*) and degree of coloration (*2.2.2*).

Solubility
Freeze-dried raw materials dissolve completely in the prescribed volume of reconstituting liquid within a specified time, at a specified temperature, as defined for the particular raw material.

Osmolality (*2.2.35*)
Within the limits defined for the particular raw material.

pH (*2.2.3*)
Within the limits defined for the particular raw material.

Elemental impurities
Within the limits defined for the particular raw material.

Total protein (*2.5.33*)
Within the limits defined for the particular raw material.

Related substances
The content of product-related substances is within the limits defined for the particular raw material.

Microbiological control
Depending on the raw material concerned, it complies with the test for sterility (*2.6.1*) or the microbial contamination is determined (*2.6.12*).

Viral contaminants
Depending on the raw material concerned, relevant virus contamination is determined.

Bacterial endotoxins (*2.6.14*)
Less than the limit defined for the particular raw material.

Mycoplasmas (*2.6.7*)
Raw materials are free from mycoplasmas.

Stabiliser
Where applicable, it complies with the limits defined for the particular raw material.

Water (*2.5.12*)
Freeze-dried raw materials comply with the limits defined for the particular raw material.

3-3-3 ASSAY

Content
The content (e.g. protein content)/composition of the raw material is determined by an appropriate qualified method.

Biological activity
Where relevant, the biological activity is determined by a suitable assay. Where relevant (e.g. for enzymes), the biological activity is expressed per milligram of total protein (specific activity).

3-3-4 REFERENCE MATERIAL OR REFERENCE BATCH

An appropriate reference material or a representative batch of the raw material is used to perform the above-mentioned identification, tests and assay. Where available, the use of established reference standards, such as European Pharmacopoeia reference standards or WHO International Standards, is recommended.

3-4 STORAGE

The shelf life and storage conditions are defined.

3-5 LABELLING

The label states the expiry date, conditions for storage and use and any code that may be required for traceability including the biological origin of the raw material.

4 SERA AND SERUM REPLACEMENTS

4-1 DEFINITION

Sera from human or animal sources and serum replacements (including platelet lysates and other undefined growth additives, conditioned media, blood and other cellular components) are used as growth additives for cell culture. Sera and serum replacements used to promote cellular growth are typically complex biological mixtures, whose exact composition is not always possible to define. Due to this complex nature, special attention is given to verifying the consistency and performance of every batch.

Bovine serum
If bovine serum is used, it complies with the monograph *Bovine Serum (2262)*.

Human serum and platelet lysates
Human serum and platelet lysates used as raw materials for the production of cell-based/gene therapy medicinal products are human blood-derived materials, which can originate from the recipient (autologous) or from another individual (allogeneic).

Conditioned media
Conditioned media, isolated and purified from cultured cell supernatant, may also be used to enhance cell proliferation due to various growth factors and cytokines secreted by the cells into the medium.

Other growth additives with undefined composition
Cell and/or tissue lysates may be used as growth additives.

Composite media
Composite media contain growth additives such as bovine serum, growth factors etc. The principles described in this section of the general chapter apply to individual ingredients of biological origin and/or biologically active ingredients of the composite media.

4-2 PRODUCTION

Due to potential differences in quality between batches of serum, cell or tissue lysate, suitable measures are implemented to verify the consistency of each batch before using them as raw materials for the production of cell-based/gene therapy medicinal products.

Because of the inherent risk of transmitting infectious agents from pooled plasma, pooled sera, or other derivatives from pooled allogeneic human blood or plasma, consideration is given to limit the number of donations which are pooled, unless sufficient methods for inactivation/removal of viruses are applied during production, where applicable.

For conditioned media, a cell bank system is preferred. The removal of the cells from the media must be ensured and potential impurities originating from these cells determined if possible.

4-3 IDENTIFICATION

It is recognised that the exact qualitative composition of sera and serum replacements may be difficult to determine. However, the approximate protein composition in both cases may be determined by, for example, protein electrophoresis. Where relevant, tests for total protein content or any chemical additives are performed. For human serum, the electrophoretic pattern corresponds to that of an appropriate serum reference batch. Alternatively, identity may be determined by comparison of albumin content with an appropriate serum reference batch. For serum replacements,

the electrophoretic pattern or the use of markers secreted by cells/platelets may be used. Human origin is determined by a suitable immunochemical method (*2.7.1*), unless otherwise justified.

4-4 TESTS

See section 3-3-2.

Haemoglobin

Where relevant, within the limits defined for the particular raw material.

Cell-derived impurities

Where relevant, within the limits defined for the particular raw material.

Specific tests for viral contaminants

For bovine serum, the tests for viral contaminants specified in the monograph *Bovine serum (2262)* apply. For human serum, the tests for viral safety specified in the monograph *Human plasma for fractionation (0853)* apply.

4-5 ASSAY

The serum or serum replacement must show cell growth promoting properties that are within the limits defined for the particular raw material. More than one type of assay may be necessary to show suitability for the intended use.

5 PROTEINS PRODUCED BY RECOMBINANT DNA TECHNOLOGY

5-1 DEFINITION

Proteins and peptides produced by recombinant DNA technology, which are used as raw materials, include growth factors, cytokines, hormones, enzymes and monoclonal antibodies.

Growth factors, cytokines and hormones They are substances typically used for stimulation or inactivation, growth promotion or differentiation of cells in cell culture systems.

Other proteins Enzymes (e.g. collagenases), as raw materials, may be used for extraction of active substances from tissues and/or fluids. Other proteins (e.g. fibronectin) may be used as culture supports or media components.

Monoclonal antibodies Used as raw materials, they include immunoglobulins and fragments of an immunoglobulin with defined specificity. Antibodies can either be conjugated (chemically modified) or non-conjugated. Typical chemical modifications include fluorescent labelling and conjugation to magnetic beads. Antibodies, as raw materials, may be used for selection, activation/stimulation, isolation or purification of cells in cell culture.

5-2 PRODUCTION

Production of proteins using recombinant DNA technology is based on a well-characterised host-vector system, using a master cell bank and, if applicable, a working cell bank derived from the master cell bank. The expressed protein is extracted and purified using a variety of techniques, such as extraction, precipitation, centrifugation, concentration, filtration and/or chromatography.

During protein production using recombinant DNA technology, process-related impurities including residual host-cell or vector DNA and host-cell proteins must be reduced to acceptable levels. Particular attention must also be given to product-related impurities.

5-3 IDENTIFICATION

Identity is established by appropriate, qualified methods, such as electrophoresis (*2.2.31*), peptide mapping (*2.2.55*), isoelectric focusing (*2.2.54*) or liquid chromatography (*2.2.29*). For antibodies, identification is based on immunoglobulin class, isotype and/or specificity. In addition to the above-mentioned methods, immunochemical methods (*2.7.1*) and determination of activity are also considered suitable for identification.

5-4 TESTS

See section 3-3-2.

Host-cell-derived proteins and residual host-cell or vector DNA

Where relevant for the particular raw material, the content of residual host-cell or vector DNA and/or protein is determined using a suitable method unless the production process has been qualified to demonstrate suitable clearance. The content is within the limits defined for the particular raw material.

Related proteins

Related proteins (e.g. polyclonal antibodies with undefined specificities, glycoforms, degradation and oxidation products, oligomers and aggregates) are determined using liquid chromatography, electrophoretic or immunological methods and are within the limits defined for the particular raw material.

5-5 ASSAY

Content

The protein content is determined by an appropriate qualified method, for example by liquid chromatography (*2.2.29*) or UV spectrophotometry (*2.2.25*).

Biological activity

The biological activity of a recombinant protein is determined using, for example, cell proliferation, cell differentiation or an enzyme assay. Several acceptable bioassays may exist for a particular protein. For antibodies, cell-based immunoassays and assays based on ligand-binding and affinity may be used.

Where relevant, the biological activity is expressed per milligram of total protein (specific activity).

6 PROTEINS EXTRACTED FROM BIOLOGICAL MATERIAL

6-1 DEFINITION

Proteins extracted from biological material and used as raw materials include enzymes (e.g. porcine - derived trypsin and endonucleases), polyclonal antibodies, other proteins of biological origin (e.g. albumin and transferrin) and peptides of biological origin. They may be of human, animal, plant or microbiological origin.

Proteins extracted from biological material are used in a wide range of applications such as growth promotion, differentiation or purification of cultured cells and extraction of active substances from tissues and/or fluids.

6-2 PRODUCTION

Proteins are extracted from the blood or tissue of animals or humans, or from plant or microbiological sources using mechanical and/or chemical techniques. They are then subjected to further purification processes using a variety of techniques such as centrifugation, filtration, chromatography and concentration.

Polyclonal antibodies are produced by immunisation with a specific antigen, followed by purification. Antibody purification involves selective enrichment or specific isolation of antibodies from serum based on physico-chemical fractionation, class-specific affinity and/or antigen-specific affinity.

During production of these proteins, process-related impurities, such as blood components, tissue fragments or contaminating proteins, must be reduced to acceptable levels. Particular attention is given to product-related impurities.

6-3 IDENTIFICATION

Identity is established by appropriate, qualified methods, such as electrophoresis (*2.2.31*), isoelectric focusing (*2.2.54*) peptide mapping (*2.2.55*), liquid chromatography (*2.2.29*) and immunochemical methods (*2.7.1*).

6-4 TESTS

See section 3-3-2.

Process-related impurities

Substances derived from the starting material (e.g. blood components, tissue fragments or contaminating proteins) are determined using suitable methods and are within the limits defined for the particular raw material.

Related proteins

Related proteins (e.g. antibodies with undefined specificity, degradation and oxidation products, oligomers and aggregates) are determined using suitable methods and are within the limits defined for the particular raw material.

6-5 ASSAY

Content

The protein content is determined using an appropriate qualified method, for example by liquid chromatography (*2.2.29*) or UV spectrophotometry (*2.2.25*).

Biological activity

Where relevant, the biological activity of a protein is determined using, for example, enzyme assays, immunoassays or assays based on cell proliferation/differentiation.
For trypsin, the assay may be performed as described in the monograph *Trypsin (0694)*.

Where relevant, the biological activity is expressed per milligram of total protein (specific activity).

7 VECTORS

Vectors that may be used as raw materials in the production of cell-based and gene therapy medicinal products include DNA vectors (e.g. plasmids, transposon vectors) as well as viral vectors and bacteria (e.g. modified *Lactococcus* species). Vectors are usually considered as starting materials, thus not under the scope of this general chapter. In cases where vectors are not considered as starting materials, such as vectors used as helper plasmids or helper viruses, the principles of this general chapter and the principles of production and quality control as outlined in general chapter *5.14.Gene transfer medicinal products for human use* are to be followed.

T. Depyrogenation of Items used in the Production of Parenteral Preparations

(Ph. Eur. general text 5.1.12)

This general chapter covers pyrogen inactivation or removal from items (primary packaging materials and equipment) coming into direct contact with the final sterilised product.

Pyrogens are substances that have the ability to induce fever when infused or injected into the body.

In this general chapter, depyrogenation is defined in terms of a reduction in lipopolysaccharide (endotoxin), the most potent and difficult-to-eliminate of pyrogenic materials.

1. DEPYROGENATION PROCESSES

1-1 DRY HEAT TREATMENT

1-1-1 Treatment conditions

Dry heat treatment is the most common depyrogenation process for glassware and other non-heat-labile materials.

A common dry heat depyrogenation cycle consists of subjecting the items to a temperature of at least 250 °C for at least 30 min; other validated combinations of temperature and time may be used, but the minimum combination required is 180 °C for 3 h.

1-1-2 Equipment

Dry heat treatment is carried out in an oven or tunnel with forced air circulation or using other equipment specifically designed for this purpose.

As a minimum, relevant dry heat depyrogenation parameters (e.g. time, temperature and, where applicable, belt speed) are monitored at the most difficult-to-heat position in the chamber, which is defined during the qualification study on the equipment.

1-1-3 Validation

All processes must be validated by adding suitable endotoxin indicators to the load at the positions identified as being the most difficult to heat (and therefore to depyrogenate) in order to verify the efficacy of depyrogenation.

1-2 OTHER PROCESSES

Other processes may be used only when heat treatment is not possible.

1-2-1 Physical treatment

Depyrogenation may also be achieved by rinsing the items with an appropriate pharmaceutical-grade water such as water for injections (WFI), with or without additional physical means.

Items must be dried following cleaning.

1-2-2 Chemical treatment

Chemical reactions using strong oxidative, alkylating or reducing agents, either liquids or vapour-phase gases, with or without heat, capable of removing pyrogens, may be applied and followed by final rinses with WFI. At the end of the treatment a verification test is carried out to detect any chemical residues.

1-2-3 Validation

All processes must be validated by adding suitable endotoxin indicators to the load at the positions identified as being the most difficult to depyrogenate in order to verify the efficacy of depyrogenation.

2. CHARACTERISTICS OF ENDOTOXIN INDICATORS

Endotoxin indicators consist of purified bacterial endotoxins (lipopolysaccharides). The following are required to be known by the user:

- name of the producer;
- composition of the indicator system if applicable;
- genus and species of the micro-organism (including the culture collection number if available) from which the endotoxin is isolated;
- specific activity of the endotoxin, in International Units per gram, per millilitre or per container;
- storage conditions and expiry date;
- batch number.

Depending on the nature of the item to be depyrogenated (e.g. glass, stainless steel, plastic), a suitable endotoxin indicator (ready-to-use or custom-made) is used during validation of a depyrogenation process.

2-1 READY-TO-USE ENDOTOXIN INDICATORS
These indicators are ampoules, vials or other carriers that have been inoculated with a known amount of endotoxin and are used to measure endotoxin reduction or inactivation in a depyrogenation process.

The type of carrier used must be representative of the item that is being depyrogenated as this may influence the effectiveness of the depyrogenation process.

2-2 CUSTOM-MADE ENDOTOXIN INDICATORS
Custom-made endotoxin indicators are items (e.g. primary packaging materials or equipment) that have been surface-inoculated with a suitable endotoxin solution (e.g. endotoxin reference standard). Once dried, the inoculated item is used to measure endotoxin reduction or inactivation in a depyrogenation process.

3. TEST PROCEDURE

3-1 RECOVERY TEST PROCEDURE OF ENDOTOXIN FROM ENDOTOXIN INDICATORS
The endotoxin recovery rate is determined on items (ready to use or custom made indicators) that are not subjected to the depyrogenation process in order to calculate the percentage recovery and to check any interference from leachables before assessing the effectiveness of a depyrogenation process.

The endotoxin recovery test must be validated.

If the endotoxin recovery rate is insufficient to demonstrate a 3.0 $\log_{10}$ reduction, the amount of endotoxin used must be adjusted accordingly.

3-2 ENDOTOXIN REDUCTION TEST PROCEDURE
Items that have been artificially contaminated with a known amount of endotoxin or ready-to-use endotoxin indicators are placed in the load to be tested. Endotoxin levels are assessed before (initial endotoxin level) and after (residual endotoxin level) the depyrogenation process according to the same validated method. The level of endotoxin per indicator and the number of indicators used for the test must be sufficiently high to allow accurate determination of the reduction in endotoxin due to the depyrogenation process.

4. CRITERIA
Not less than a 3.0 $\log_{10}$ reduction in recoverable endotoxin is used as the criterion for process validation. The $\log_{10}$ reduction is calculated by determining the measured $\log_{10}$ of recoverable endotoxin in the unprocessed item minus the measured $\log_{10}$ of recoverable endotoxin remaining in the processed item.

U. Multivariate Statistical Process Control

(Ph. Eur. general text 5.28)

The following chapter is published for information only. It is an introduction to the use of multivariate statistical process control (MSPC) for monitoring and controlling manufacturing processes. The objective is to provide guidance on good practice. This chapter complements general chapter 5.21. Chemometric methods applied to analytical data.

1 INTRODUCTION
In pharmaceutical manufacturing, statistical process control (SPC) is an established tool to control and improve process performance and to reduce the variation of key parameters. These parameters may be either critical performance characteristics of the process or critical quality attributes (CQA) of the product, which are referred to in the rest of the text as 'process variables' and 'product variables' respectively. SPC is implemented by means of control charts that show the changes in the values of these variables, measured from samples or directly from the process and plotted against sample number or time.

SPC applied to a single or a few independent variables involves a univariate approach (each variable is analysed separately). However, process performance usually depends on many parameters. Moreover, process analytical technology (PAT) now makes it possible to measure directly many variables at high frequency. Hence, the input measurements for SPC are not necessarily simple scalar values (such as temperature or pH), but might also be more complex (such as spectra or analytical data from several sources). Since the set of all measurements at a certain point in time characterises one state of the process, interdependencies among the many measurements are expected and hence the measurement variables may be correlated.

Multivariate statistical process control (MSPC) can be defined as the application of multivariate statistical techniques in order to analyse complex process data with potentially correlated variables. MSPC in combination with automated data collection and analysis may be used to generate control charts based on a multivariate (chemometric) model. These control charts can be used to monitor a process or adjust it. MSPC in combination with a high degree of automation may facilitate continuous manufacturing (CM) as well as real-time release testing (RTRT). It can be combined with PAT (see general chapter *5.25. Process analytical technology*), quality by design (QbD) and design of experiments (DoE), in line with relevant ICH guidelines.

Many different activities in pharmaceutical manufacturing may rely on MSPC, such as:
— process development;
— monitoring of production operations;
— process optimisation, lifecycle management;
— trouble shooting, fault detection, root cause analysis;
— improvement of process understanding.

2 STATISTICAL PROCESS CONTROL (SPC)
Although univariate SPC is not the subject of this chapter, aspects of SPC that are required to understand MSPC are described below.

2-1 DEFINITION
Univariate SPC uses measurements of a variable over time. These measurements may be performed off-line, in-line, at-line, or on-line (see definitions in general chapter *5.25*). The aim is to characterise the time course of the variable when the process is operating normally, which is referred to as the in-control state. With this information, the process can be monitored to ensure that the distribution of the monitored variable does not change as the process runs. If the variable distribution stays constant, the process is said to be in statistical control.

When the process is developed or significantly changed, the variable distribution is not yet known, and process data therefore have to be gathered to develop a model (phase I). In a retrospective analysis of these data, using trial control charts, it is determined if the process was in control when the data were collected. If the process was in control, the data can be used to construct the final control charts. If not, the trial control charts are used to investigate atypical results and outlying data points (root cause analysis) to bring the process under control. Once the final control charts have been

constructed with in-control process data (i.e. a clean set), phase I ends and the monitoring phase starts (phase II). During this phase, control charts are used prospectively to check whether the process is in control or whether action is necessary to keep it in control.

2-2 DEVELOPMENT OF CONTROL CHARTS

Control charts are constructed by collecting a set of samples of n consecutive measurements (rational subgroups). For a control chart of means ($\bar{x}$), here taken as an example, the averages $\bar{x}_i$ ($i = 1, \ldots, m$) of each of the m subgroups are computed next. Averages of sufficiently large subgroups likely follow an approximately normal distribution, which facilitates the setting of the control limits. The averages $\bar{x}_i$ are then plotted against sample number i or time t_i. The $\bar{x}$-control chart consists of a baseline (or centre line) $\bar{\bar{x}}$ equal to the grand mean ($\bar{\bar{x}}$) value of the variable (e.g. the mean content of the product) when the process is in statistical control. There are 2 additional lines, one above and one below the centre line, called the upper control limit (UCL) and the lower control limit (LCL).

The control limits are set so that the average of a rational subgroup $\bar{x}$ has a very low probability of falling outside them if the process is in control. If an average falls outside the limits, this is an indication that the distribution of the variable may have changed, in which case some kind of action is necessary to bring the process back under control.

The control limits (CL) depend on the variable's standard deviation and the size of the subgroups as follows:

$$CL = \bar{\bar{x}} \pm L \times \frac{\hat{\sigma}}{\sqrt{n}}$$

$\bar{\bar{x}}$ = grand mean, the mean of all the subgroup averages $\bar{x}_i$ in the clean data set from phase I;
$\hat{\sigma}$ = pooled standard deviation of the single measurements making up the subgroups;
n = size of the subgroups (constant sample size assumed here);
L = factor derived from the normal distribution that controls the risk of a false alarm.

In this expression, the quotient $\frac{\hat{\sigma}}{\sqrt{n}}$ is the standard deviation of the mean ($\bar{x}$), also referred to as the standard error. The control limits are set at $\pm$ L times this standard deviation above and below the centre line. The choice of L influences the risk of a false alarm when the process is in control (false positive, error of the first kind). With $L = 3$, the risk of false alarms is very low (0.27 per cent) if the averages $\bar{x}_i$ actually follow a normal distribution.

The subgroup size n influences the risk of not detecting a mean shift in the process (false negative). The sampling frequency is also important since the time interval from the occurrence of an event (i.e. an out-of-control signal) to its detection depends on it.

The procedure described above using the $\bar{x}$-control chart as an example is also applicable to other types of control charts of various statistical parameters. Control charts developed according to these principles are often called Shewhart control charts. However, many different extensions and more-complex univariate control charts also exist, for example control charts for dispersion measures such as the standard deviation.

3 MULTIVARIATE STATISTICAL PROCESS CONTROL (MSPC)

3-1 INTRODUCTION

A multivariate approach is necessary if several potentially correlated variables need to be analysed simultaneously. Theoretically, multivariate (high-dimensional) data could be analysed by setting up a univariate control chart for each variable. This approach is in principle correct if all measurement variables are uncorrelated. However, this is rarely the case. If some variables are correlated, the use of many univariate control charts instead of one multivariate chart increases the risk of not detecting an out-of-control state (see Figure 5.28.-1). This is because the use of several univariate control charts can only detect points outside the whole data space, while correlated variables vary only within a certain subspace of the whole data space spanned by the ranges of all individual variables. MSPC makes it possible to find this subspace and identifies values that are outside this subspace, i.e. samples that do not follow the general correlation pattern (see section 4. Theoretical background). MSPC is therefore more sensitive for out-of-control signals and is a better diagnostic tool in such situations.

3-2 DEFINITION

MSPC uses statistical procedures to monitor simultaneously many interrelated variables, combined in a measurement vector (see section 4. Theoretical background). These variables may form a set of variables with a high level of correlation (e.g. a spectrum), but some variables may also be mutually uncorrelated. Importantly, the relationships (correlations) existing between the different variables are exploited in MSPC. Control charts based on multivariate measurements follow the same principles as Shewhart control charts. The main difference is that a summary statistic considering the entire measurement vector is plotted against time or sample number. That way, the multivariate input data are transformed into a control statistic that can be monitored much like the single parameter in a univariate control chart. For instance, mean changes in a process can be monitored in a chart by computing the distance between measurement vectors for newly acquired data and the in-control mean vector. Hotelling's T^2 and Q statistics (squared prediction error or squared residuals) are the most widely used distance measurements. Hotelling's T^2 takes the deviation of all measurement variables from their process mean into account, with each deviation weighted according to the natural variation of that variable and its relationship to all other variables. Q statistics can be used to complement T^2 since it corresponds to the deviations that T^2 does not model. By taking the relationships between variables into account, unusual patterns in the deviations can be detected, which result in large distances from the in-control mean.

The information needed is obtained from the inverse of the sample covariance matrix, where the latter needs to be estimated from in-control process data. If each entry in the multivariate measurement vector is normally distributed, and if each measurement vector is independent of those taken at other time points (or with other samples), the natural variability of T^2 for a process in statistical control follows a known distribution (see section 4. Theoretical background), which can be used to derive the UCL. If T^2 is larger than the UCL, the process is thought to be out-of-control. Since the smallest conceivable value of T^2 is zero (i.e. the measurement vector and the process mean vector coincide), which is considered the ideal case, there is no LCL when using T^2.

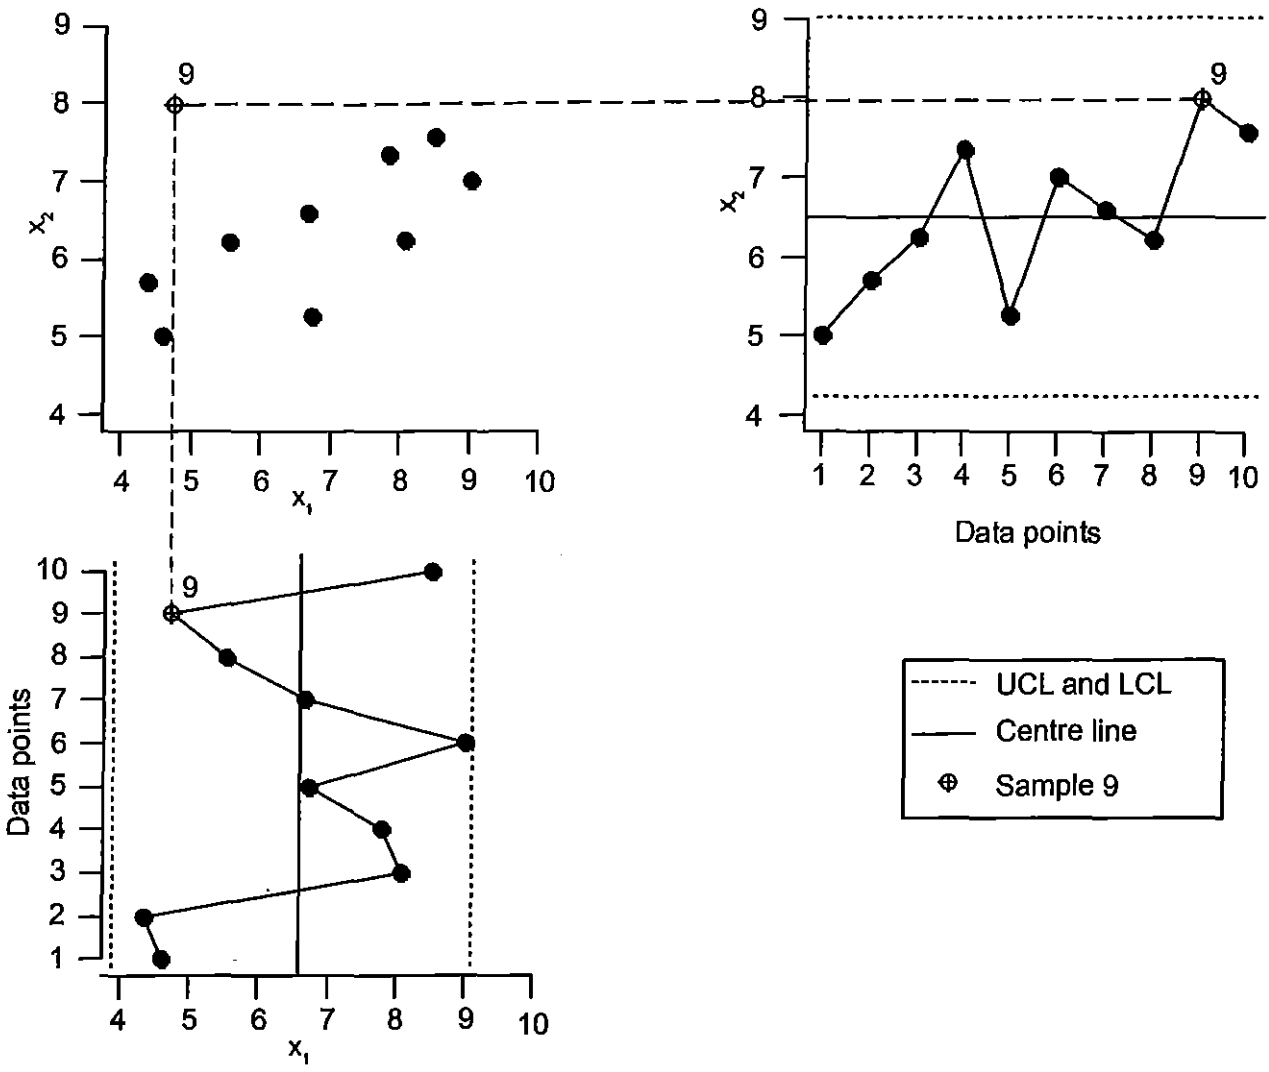

Figure 5.28.-1. – *Univariate and multivariate graphical representations of x_1 and x_2. While sample 9 is inconspicuous (i.e. in-control) in the univariate control charts, sample 9 is noticeable as an anomaly in the multivariate space*

Optimal application of MSPC may require a preliminary evaluation of variables. If all variables cannot be considered as equally important, weighting can be applied to variables. Some variables might be of less importance and at the same time trigger unnecessary signals that might increase the risk of a false alarm. Furthermore, variables can fall into different groups, e.g. raw material quality parameters or parameters associated with different steps of the process. Rather than merely grouping all variables into a single analysis, a separate T^2 plot for each of the distinct groups of variables might be more efficient.

MSPC is applicable to continuous as well as batch processes. In both cases, the production process is monitored over time using T^2 and Q statistics employing the specific control limits for the different stages of production. These limits may be established based on the variability of a set of batches or can be based on the variability of a number of samples within a certain time frame of a continuous process.

The computations for batch data are not described in this chapter.

3-3 DEVELOPMENT OF MULTIVARIATE CONTROL CHARTS

Method development of multivariate control charts is also subdivided into phases I and II. Once again, phase I includes planning, development and estimation of the model. Preliminary data are collected under proper operational conditions and examined for statistical control and potential problems. Due to the high number of variables, preliminary data analysis is far more extensive than in the univariate case. Attention should be paid to data-collection procedures, potential data-transmission errors, theoretical relationships between the variables, necessary pre-processing of the variables, potential for and handling of missing data, detection of statistical outliers, handling of variable correlations, and the potential for autocorrelated errors, i.e. time-dependent, slowly varying error sources, which would cause a violation of the aforementioned independence assumption. Once statistical control for the preliminary data is established, they can be used to estimate the necessary model parameters. In particular, computing T^2 requires estimating and inverting the covariance matrix for this sample of data (to obtain the weighting factors, see above). Estimating the many parameters of a covariance matrix requires a large enough sample of in-control process data

from phase I. Sample size particularly matters if process-dispersion control charts are also to be constructed. These charts display either the determinant (the so-called generalised variance) or the trace of the covariance matrix and require good estimates of the sample covariance matrix to be useful. With highly correlated measurement data, inverting the covariance matrix may not be possible or may be numerically unstable. In such cases, the raw measurement data are first reduced in dimensionality by principal component analysis (PCA) or partial least squares regression (PLS) (see general chapter *5.21*). The raw data are then replaced by PCA or PLS scores after selection of the optimal number of principal components or PLS factors. This reduction step is the rule rather than the exception for high-dimensional measurement data and enables the computation of control statistics such as T^2 even for highly correlated data.

Once control chart development is finished, the chart can be used in phase II for process monitoring. Here, a control statistic such as T^2 or Q is computed for newly acquired measurements to determine if the process is in control. It is plotted against time or sample number and compared with its UCL. It should be noted that the value of the control statistic depends on the entire measurement vector. When an out-of-control situation occurs, the measurement vector is very different from the mean vector. To find out which variable(s) caused the out-of-control signal, the contribution of each variable to T^2 or Q is computed. Variables with large contributions are examined preferentially during root cause analysis (see section 4. Theoretical background).

3-4 MAINTENANCE

Model maintenance ensures ongoing performance such as maintaining a low risk of false alarms and false negatives. Changes are required if the correlation structure or the mean of some variables slowly change during long-term periods without the control statistic falling outside the control limits. Maintenance encompasses updating model parameters and control limits. In the case of T^2 charts, this amounts to re-estimating the sample covariance matrix and adapting the control limits to the sample size of the new phase I. Maintaining the model can be done by periodically rebuilding the model off-line or by automatically updating it. Setting the parameters for automatic methods is critical and requires a deep understanding of the process, since automatic updates may mask real trends in the process. Maintenance may also be necessary if process conditions or raw materials have changed or if instruments have been exchanged or recalibrated.

4 THEORETICAL BACKGROUND

4-1 BASIC PRINCIPLES OF MULTIVARIATE CONTROL CHARTS

MSPC uses multivariate statistical procedures, the basic principles of which are given in general chapter *5.21. Chemometric methods applied to analytical data*. Key techniques for MSPC are the latent variable methods PCA (general chapter *5.21*, section 2-1) and PLS (general chapter *5.21*, section 2-8), which reduce the dimensionality of the raw input data by projecting them onto a lower dimensional subspace. This dimension reduction is possible whenever the raw input data are correlated, which is almost always the case. The signals monitored in the low dimensional space are referred to as latent variables and can be thought of as source signals of the process. Since the number of latent variables is rarely known *a priori*, another key technique for MSPC is the data-driven choice of the number of latent variables, which is commonly accomplished by resampling techniques such as cross-validation (general chapter *5.21*, section 1-3-2-1).

4-1-1 Hotelling's T^2

Let $\mathbf{X}$ be an $n \times m$ matrix that holds, for example, m process variables measured at n different time points. Define the vector $\bar{\mathbf{x}}$ as the column means of $\mathbf{X}$:

$$\bar{\mathbf{x}} = (\mathbf{X}^T \mathbf{1}_n) / n$$

and let $\mathbf{X}_c$ be the column mean-centred measurement matrix:

$$\mathbf{X}_c = \mathbf{X} - \mathbf{1}_n \bar{\mathbf{x}}^T$$

The estimator of the sample covariance $\mathbf{C}$ is then given by:

$$\mathbf{C} = \frac{1}{n-1}(\mathbf{X}_c^T \mathbf{X}_c)$$

An important multivariate control chart is based on T^2:

$$T^2 = (\mathbf{x}_o - \bar{\mathbf{x}})^T \mathbf{C}^{-1} (\mathbf{x}_o - \bar{\mathbf{x}}) = \mathbf{x}_{c,o}^T \mathbf{C}^{-1} \mathbf{x}_{c,o}$$

where $\mathbf{x}_o$ is an $m \times 1$ vector of raw measurements measured at a new time point o and $\mathbf{x}_{c,o}$ is the corresponding mean-centred measurement vector. T^2 represents the squared Mahalanobis distance of the new measurement vector $\mathbf{x}_o$ from the process mean vector $\bar{\mathbf{x}}$. T^2 can only be used directly on the raw measurements for a few uncorrelated variables. If the dimension m becomes large and the measurement variables are correlated, matrix $\mathbf{C}$ becomes ill-conditioned or singular and can no longer be inverted. If this happens, the raw variables are replaced by latent variables. With PCA, the raw data are replaced by the scores $\mathbf{T}$ or $\mathbf{t}_o$:

$$\mathbf{T} = \mathbf{X}_c \mathbf{P}$$

$$\mathbf{t}_o = (\mathbf{x}_{c,o}^T \mathbf{P})^T = \mathbf{P}^T \mathbf{x}_{c,o}$$

Here, the score matrix $\mathbf{T}$ and the score vector $\mathbf{t}_o$ are of dimension $n \times q$ and $q \times 1$ respectively ($q < m$), and the principal component loadings matrix $\mathbf{P}$ is of dimension $m \times q$. The number of latent variables (q) is a hyperparameter of the model and needs to be estimated, e.g. by cross-validation. Postmultiplication of the raw process data $\mathbf{X}_c$ (or $\mathbf{x}_{c,o}^T$) by the orthonormal matrix $\mathbf{P}$ projects them into a lower dimensional subspace where the main process characteristics can be monitored. $\mathbf{P}$ holds the first q eigenvectors of the sample covariance matrix $\mathbf{C}$. It is chosen to capture all relevant information of the process (i.e. common cause variation) while omitting noise. With the substitution of the raw process variables by the respective principal component scores, T^2 in the process-relevant subspace becomes:

$$T^2 = \mathbf{t}_o^T \Lambda^{-1} \mathbf{t}_o = \sum_{i-1}^{q} \frac{t_{o,i}^2}{\lambda_i}$$

where Λ is the $q \times q$ diagonal matrix of eigenvalues of the sample covariance matrix $\mathbf{C}$ and λ_i is the i^{th} diagonal element of Λ. In principal component space, T^2 is defined in terms of the eigenvalues and eigenvectors of the sample covariance matrix $\mathbf{C}$. Here, λ_i reflects the variance of the i^{th} score vector $\mathbf{T}_i$:

$$\lambda_i = \frac{1}{n-1}(\mathbf{T}_i^T \mathbf{T}_i)$$

where $\mathbf{T}_i$ is the i^{th} column of matrix $\mathbf{T}$. In general, for T^2 to be properly scaled in latent variable space, λ_i has to reflect the variance of the i^{th} score vector. This scaling is important for the transition from PCA to PLS in order to keep the

distributional properties of T^2 compliant with the definition of the UCL.

Under the assumption that the measurement vectors X follow a multivariate normal distribution and the covariance matrix has been estimated from phase I data, the critical value $T^2_{UCL,1-\alpha}$ for phase II (monitoring) follows an F-distribution:

$$T^2_{UCL,1-\alpha} = \frac{(n^2-1)\times q}{n\times(n-q)} \times F(q, n-q, 1-\alpha)$$

where $F(q, n-q, 1-\alpha)$ is the $1-\alpha$ percentile of the F cumulative distribution function with q and $n-q$ degrees of freedom and α is the probability of an error of the first kind (i.e. the risk of a false alarm). This critical value for the UCL is valid under the assumption that the sample covariance matrix has been estimated in phase I and is thus independent of the monitored measurement vector $\mathbf{x}_o$. Hence, the latter critical value is valid for phase II. For trial control charts in phase I, where this assumption is not fulfilled, the critical value follows a beta distribution.

PCA projects the raw process variables into a lower dimensional subspace. However, the out-of-control signal does not necessarily lie in that subspace. If it is known that such a signal manifests itself in certain latent variables, then these latent variables may be monitored individually in addition to T^2.

4-1-2 Q statistics (squared prediction error or squared residuals)

In general, solely monitoring the process by T^2 is not sufficient since an out-of-control process may move away from the subspace being monitored. New events of this kind can be detected by assessing how well the q-dimensional score vector $\mathbf{t}_o$ approximates the mean-centred measurement vector $\mathbf{x}_{c,o}$. This is done by projecting $\mathbf{t}_o$ back into the original data space and comparing this approximation of the measurement vector $\hat{\mathbf{x}}_{c,o}$ to the actual $\mathbf{x}_{c,o}$:

$$Q = \| \mathbf{x}_{c,o} - \mathbf{P}\,\mathbf{t}_o \|^2 = \| \mathbf{x}_{c,o} - \hat{\mathbf{x}}_{c,o} \|^2$$

Here, $\|a\|$ refers to the Euclidean norm of vector a. Q is the squared prediction error of $\hat{\mathbf{x}}_{c,o}$ which is routinely monitored in addition to T^2. The control limit for Q is difficult to obtain, but different approximations can be found in the literature.

Let $\mathbf{Y}$ be an $n \times r$ matrix of r product variables measured at the same n time points as the process variables in the aforementioned matrix $\mathbf{X}$. Using the $\mathbf{X}$ and $\mathbf{Y}$ data, PLS makes it possible to extract latent variable scores $\mathbf{T}$ that explain the process variables (matrix $\mathbf{X}$) and are predictive for the product variables (matrix $\mathbf{Y}$).

Apart from the construction of the latent variable scores, which is different in PLS compared with PCA, the variability of novel data $\mathbf{x}_o$ is monitored in the same manner as when the product variables are not considered (see previous section). What changes is the way the data $\mathbf{x}_o$ are projected into the q-dimensional subspace to yield $\mathbf{t}_o$, since PLS uses different criteria for doing this. In addition to the analogous Q statistics for the process variables (X), in PLS there are also Q statistics for the prediction error of the product variables (Y):

$$Q = \| \mathbf{y}_{o,c} - \hat{\mathbf{y}}_{o,c} \|^2$$

where $\mathbf{y}_{o,c}$ is a mean-centred new vector of product variables and $\hat{\mathbf{y}}_{o,c}$ is the prediction of the q-dimensional PLS model. Again, q is a hyperparameter of the model, which needs to be estimated, e.g. by cross-validation. Since the construction of the Q statistics in PLS differs from PCA, the approximation of the critical values also changes.

4-1-3 Linear and non-linear methods

In most cases, linear methods (such as those described here) are sufficient for monitoring a process trajectory since small process changes can be approximated reasonably well by linear techniques. If certain measurement variables are non-linearly related to the process, it may be necessary to re-express them by a transformation to obtain a better linear relationship. Non-linear PCA is needed for applications where the variables display non-linear interrelationships in in-control state. In this case kernel PCA is often used in non-linear MSPC since determining the UCL for kernel PCA is particularly straightforward.

4-1-4 Critical aspects

The latent variable methods described in this chapter are sensitive to the scale of the variables. Process variables, or even product variables, may have to be weighted differently.

Latent variables associated with a small variance of the scores may easily cause out-of-control signals even though the observed variation is practically negligible. This is because small values for λ_i in the denominator of T^2 amplify small (practically negligible) deviations in $t_{o,i}$. This fact emphasises the importance of a careful selection of the number of latent variables q.

T^2 is intended to monitor changes in the process mean characteristics. However, it measures shifts in mean and variance of the recorded measurements simultaneously and is very sensitive towards changes in variance (see above). While it is important to know about shifts in variance, it would be preferable to have separate control charts for location (i.e. the process mean) and dispersion (i.e. the process covariance matrix).

In the case of MSPC applied to batch production, it is important to synchronise the monitoring of the various batches, in terms of either the process time or the process stage, to ensure that the batch trajectories are compared at the same stages defined in physical chemical terms rather than temporally.

4-2 BASIC PRINCIPLES OF FAULT DIAGNOSIS

Latent variable methods provide process operators with tools to diagnose which variables caused the out-of-control signal, which in turn may help to investigate the root cause (fault diagnosis). For T^2 charts, the scores where the out-of-control signal manifests itself in $\mathbf{t}_o$ are first identified. This is done by plotting the i^{th} normalised score $t^2_{o,i}/\lambda_i$ against i ($i = 1, \ldots, q$), and those scores with high values are further inspected by computing variable contributions. Let k be the dimension where the score vector shows an unusually high value. It is possible to re-express the k^{th} contribution to T^2 so that the impact of each raw variable can be seen:

$$T^2_k = \frac{t^2_{o,k}}{\lambda_k} = \frac{\sum_{j=1}^{m} \left(P_{kj} \times (x_{oj} - \bar{x}_j)\right)^2}{\lambda_k}$$

where $p_{k,j}$ is the loading of the k^{th} latent variable for the j^{th} original variable and $x_{o,j}$ and $\bar{x}_j$ are the corresponding components of the measurement vector $\mathbf{x}_o$ and the column mean vector $\bar{\mathbf{x}}$. By plotting each individual normalised summand $\left(P_{kj} \times (x_{oj} - \bar{x}_j)\right)^2/\lambda_k$ against the corresponding variable index j, the contribution of each measurement $x_{o,j}$ to T^2_k can be displayed in order to identify highly influential variables. The variables causing the out-of-control signal will be far from the corresponding variable mean in either

direction. The procedure for PLS is very similar. The loading $p_{k,j}$ needs to be replaced by the corresponding weight $w_{k,j}$, where $\mathbf{w}_k$ is the weight vector that generates the k^{th} PLS score vector $\mathbf{t}_k = \mathbf{X}_c \mathbf{w}_k$.

For Q charts the contribution of the j^{th} variable is given by:

$$\left(x_{c,o,j} - \hat{x}_{c,o,j}\right)^2,\ j = 1, \ldots,\ m$$

where $x_{c,o,j}$ and $\hat{x}_{c,o,j}$ are the j^{th} elements of the vectors $\mathbf{x}_{c,o}$ and $\hat{\mathbf{x}}_{c,o}$, respectively. Again, the individual contributions can be plotted against j to identify influential variables visually.

4-2-1 Critical aspects

Contribution plots help to identify variables or groups of variables that contribute numerically to the out-of-control signal. Hence, they highlight variables that are related to the fault instead of revealing the actual cause of it. The root cause still needs to be elucidated by finding the event that caused the state of the highlighted variables.

Supplementary Chapter V

Unlicensed Medicines

This section gives guidance to prescribers, manufacturers and suppliers of unlicensed medicines on the legal and ethical considerations of such medicines. It also provides guidance on the standards for the preparation and manufacture of unlicensed medicines.

Introduction

The term "unlicensed medicine" means either a medicine prepared under a Manufacturer's 'Specials' Licence or a medicine that is prepared extemporaneously under the supervision of a pharmacist.

Unless exempt, medicines for human use must have a Marketing Authorisation (also known as a Product Licence) before being placed on the market in the UK. There is an exemption provided by the medicines legislation to allow the supply of unlicensed medicines which are also known as 'Specials'[1]. A 'Special' may only be supplied to meet the special needs of an individual patient and may only be manufactured by the holder of a Manufacturer's 'Specials' Licence. The decision on whether an individual patient has special needs is made by the authorised healthcare professional responsible for the patient's care.

The UK medicines legislation also allows a pharmacist to prepare an unlicensed medicine for supply in accordance with an authorised healthcare professional's prescription[2]. Such circumstances can arise where no licensed product is available or where the formulation of the licensed product is not suitable. This activity is known as extemporaneous preparation.

The use of unlicensed medicines in the UK is widespread, mainly in the hospital sector and also in primary care. There are a number of reasons for this including:

1. requirements for liquid formulations for paediatric and geriatric populations;
2. discontinued supply of licensed medicines;
3. specialist products used in hospitals;
4. novel therapies in hospitals and clinics;
5. low demand critical care products.

An unlicensed medicine by its very nature will not have been licensed by the UK Licensing Authority or the European Commission and, therefore, will not have been assessed by them for its safety, quality or efficacy. Since 'Specials' are manufactured in accordance with Good Manufacturing Practice (GMP), in facilities licensed by the Medicines and Healthcare products Regulatory Agency (MHRA), there is some assurance of the manufacturing quality and hence the safety related to quality. However, the intrinsic safety and efficacy of 'Specials' are not assessed and are the responsibility of the prescriber.

Legal Requirements

'Specials'

The legislative provision for the supply of unlicensed medicines known as 'Specials' is contained within Regulation 167 of the Human Medicines Regulations 2012 ("Exceptions to Requirement for Marketing Authorisation etc"). This states *inter alia* that, in order to fulfil special patient needs, medicinal products supplied in response to a *bona fide* unsolicited order, and formulated in accordance with the specifications of an authorised healthcare professional, and for use by an individual patient under their personal direction, may be excluded from the requirements to have a Marketing Authorisation. Regulation 167 is subject to a number of conditions which are:

(a) the product is supplied to a doctor, dentist, nurse independent prescriber, pharmacist independent prescriber or supplementary prescriber or for use in a registered pharmacy, a hospital or a health centre under the supervision of a pharmacist;

(b) no advertisement or representation relating to the product is issued;

(c) the manufacture or assembly of the product is carried out under the supervision of such staff and such precautions are taken to ensure that the product meets the specifications of the doctor, dentist, or supplementary prescriber who requires it;

(d) written records as to the manufacture or assembly are made and maintained and are available to the licensing authority;

(e) the relevant medicinal product is manufactured or assembled by the holder of a Manufacturer's 'Specials' Licence;

(f) the product is distributed by way of wholesale dealing by the holder of a Wholesale Dealer's Licence.

It should also be noted that 'Specials' may be imported to fulfil the special needs of an individual patient. Importation should be in accordance with the 2012 regulations relating to Manufacturing and Wholesale Dealing[3] and importers of such products must hold the requisite licences. Imported 'Specials' are outside the scope of the General Monograph on Unlicensed Medicines. However, where an individual monograph exists for an imported 'Special', then the product must comply.

Extemporaneous Preparations

The 1968 Medicines Act ("the Act") allows a pharmacist to prepare or dispense a product which does not have a Marketing Authorisation in response to a prescription from an authorised healthcare professional. The exemptions which apply to pharmacists are contained in Section 10 of the Act. Under the exemptions, the licensing requirements of the 2012 Regulations for a Marketing Authorisation or relevant Manufacturer's Licence do not apply when preparing or dispensing a medicinal product in a registered pharmacy, a hospital, a care home service or a health centre, by or under the supervision of a pharmacist in accordance with a prescription given by an authorised healthcare professional. Under Section 10 of the Act a pharmacist may also prepare a stock of medicinal products for dispensing under the same conditions and procure the preparation or dispensing of an unlicensed product in accordance with the prescription of an authorised healthcare professional.

In addition, Regulation 4 of the 2012 Regulations sets out further provisions in relation to activities conducted under Section 10 of the Act which pharmacists have to follow. These provisions relate to information and labelling provisions that must appear on the packaging of a pharmacy prepared and dispensed medicine.

Ethical Considerations and Guidance

The underlying principle of medicines legislation is that, subject to specific exemptions, no medicinal product may be placed on the market without an appropriate Marketing Authorisation. The exemptions from the formal licensing requirement allow a practitioner to prescribe and a

pharmacist to supply an unlicensed medicine subject to certain conditions. However, in these circumstances both the prescriber and the pharmacist have a duty of care to the patient receiving the unlicensed medicine.

In developing an unlicensed medicine an appropriate risk assessment should be undertaken, which includes consideration of the suitability and fitness of purpose of the drug product. The risk assessment should also consider the contribution of the excipients to the safety profile of the unlicensed medicine.

Following recommendations from the Commission on Human Medicines restricting the amount of *chloroform* in oral medicines, the use of *chloroform* as an ingredient in unlicensed preparations should be avoided.

The MHRA have issued guidance on the supply of Unlicensed Medicines known as 'Specials' in the UK which advises on the manufacture, importation, distribution and supply of such products[4]. It also advises that where a suitable licensed equivalent product is available, an unlicensed product must not be used.

The Royal Pharmaceutical Society (RPSGB) has issued guidance for registered pharmacies on preparing unlicensed medicines, the procurement and supply of 'Specials' and on the prescribing of 'Specials'[5,6,7]. This guidance aims to support pharmacists and their teams to work with prescribers, patients and carers to ensure the safe and appropriate procurement and supply of 'Specials'.

Since there is a greater demand for unlicensed medicines for the treatment of children, due to the lack of suitable licensed formulations, a joint committee of the Royal College of Paediatrics and Child Health (RCPCH) and the Neonatal and Paediatric Pharmacists Group (NPPG) has published a statement providing guidance to health professionals and parents who prescribe, dispense or administer medicines for children[8]. It recognises the need to use some unlicensed medicines in paediatric practice since for many medicines authorised for children there is no appropriate dosage form, whilst for other medicines there is no paediatric authorisation but their use is established. The RCPCH and NPPG Joint Committee on Medicines have also produced information leaflets for parents and older children on the use of unlicensed medicines[9].

Communications to those patients or carers of patients who receive unlicensed medicines can be of paramount importance. Patients need to be reassured that unlicensed medicines are not "second-class" healthcare products and that the treatment has been carefully thought out by the prescriber and is in the best interests of the patient. Where a medicine has been manufactured in a licensed 'Specials' facility, the manufacturing activities will have been approved by the MHRA, thus providing some assurance of product quality. Patients and carers may not always know that the medicines they have received are unlicensed but both prescriber and pharmacists should be prepared to discuss these issues if they are raised.

Labelling of Unlicensed Medicinal Products

The labelling of medicines is a critical contributor to patient safety. Licensed medicines must comply with the requirements set out in Part 13 of the Human Medicines Regulations in respect of their labelling and Patient Information Leaflets[10]. However, this regulatory requirement does not extend to unlicensed medicines. There is a need for a standard, consistent approach to the labelling of unlicensed medicines so that purchasers and suppliers are aware of the composition and status of the product and can make a more informed judgement with regard to their liabilities. This is particularly relevant to those products produced on a batch scale by licensed 'Specials' manufacturers.

Best practice guidance on the labelling and packaging of licensed medicines advises that certain items of information are deemed critical for the safe use of the medicine[11]. These critical items of information, which should be located together on the pack and appear in the same field of view, are: name, strength, route of administration, dosage and warnings. This guidance is equally applicable to unlicensed medicines. Advice on warning statements is also available and may be applicable to unlicensed medicines[12].

Standards for Preparation and Manufacture of Unlicensed Medicines

In the UK unlicensed medicines will be prepared either by the holder of a Manufacturer's 'Specials' Licence, within the exemption provided by Regulation 167 of the 2012 Regulations, or under the supervision of a pharmacist, within the exemption provided by Section 10 of the Act.

As a general rule, it is expected and advised that batch manufacture of medicines for human use should be undertaken in licensed manufacturing units and that preparation under the Section 10 exemption will be of individual products to fulfil the requirement of an authorised healthcare professional's prescription. It is recognised, however, that there will be overlap between these two activities. Manufacturer's 'Specials' Licence holders can manufacture single individual preparations and limited batch preparation is possible under the exemption provided in Section 10 of the Act. Manufacturer's 'Specials' Licence holders are inspected regularly by MHRA GMP inspectors. The continuation of their licence is conditional upon compliance with GMP requirements. It is for this reason that it is advised that batch manufacture of unlicensed medicines is carried out in such licensed units. Unlicensed preparation activities under the supervision of a pharmacist are not inspected by the competent authority and are not independently audited. The following guidance applies equally well to products manufactured under a Manufacturer's 'Specials' Licence and those prepared under the exemption provided by Section 10 of the Act , but is more relevant to preparation under the Section 10 exemption.

The manufacture or preparation of unlicensed medicines should be in accordance with appropriate current standards of GMP and, where applicable, good dispensing practice.

The manufacture or preparation of unlicensed medicines should only be undertaken by competent staff within suitable facilities and using equipment appropriate for the scale of manufacture and specific dosage form.

Where such a monograph is available, the medicinal substance and any excipients must comply with the specific monograph requirements of the Pharmacopoeia.

The medicinal substance and any excipients must also comply with the General Monograph for Substances for Pharmaceutical Use and, where appropriate, the provisions of Supplementary Chapter IV J on the Control of Impurities in Substances for Pharmaceutical Use and the General Monograph for Products with Risk of Transmitting Agents of Animal Spongiform Encephalopathies.

Unlicensed medicinal products must comply with the requirements of the General Monograph for Pharmaceutical Preparations, with the requirements of the General Monograph for Unlicensed Medicines and with the requirements of the relevant General Monograph for the

specific dosage form. Where a BP monograph for a formulated preparation is available, the product must comply.

Further guidance on tests to be applied to the finished dosage form is also contained in Supplementary Chapters III C (Monograph Development: Guidance to Manufacturers), III D (Monograph Development: Methods of Analysis) and III F (Validation of Analytical Procedures).

A. Monograph Selection: Unlicensed Medicines

This section provides an outline of the criteria by which monographs for unlicensed products that are produced to meet particular patient needs are selected for inclusion in the British Pharmacopoeia. Such products are manufactured under a Manufacturer's 'Specials' Licence or prepared extemporaneously under the supervision of a pharmacist.

The British Pharmacopoeia Commission will consider a monograph for inclusion in the British Pharmacopoeia in the following circumstances:

1. The formulation is widely used (for example: products in the top 100 list of items used in hospitals; products identified by members of the Expert Advisory Group on Unlicensed Medicines).

2. There is a particular need based on the therapeutic category and/or the importance of the material concerned; the latter being particularly relevant to small patient populations.

3. A request is received from the Competent Authority [Medicines and Healthcare products Regulatory Agency (MHRA)].

4. A request is received from a Specials manufacturer for one of their own products.

5. A request is received from official bodies [such as the World Health Organization (WHO)].

6. Other circumstances considered on a case-by-case basis.

It should be noted that compliance with any of the above criteria will not necessarily mean that a monograph will be included in the British Pharmacopoeia. The British Pharmacopoeia Commission may decide not to elaborate a monograph for a number of reasons, including resource limitations or other circumstances, decided on a case-by-case basis.

B. Preservative-free Unlicensed Medicines

Pharmaceutical products that are intended for multiple-use after opening are required to contain suitable preservatives that will minimise the risk of microbiological contamination during manufacture and storage, after opening and during use. There is limited information on the acceptability and safety of preservatives for neonates and young children. In the first few months of life, immature physiology and metabolism may mean that preservatives considered safe in adults or older children are not appropriate for the very young. One of the reasons that an unlicensed form of a licensed formulation is developed is the need for a preservative-free preparation. Oral medicines for neonates and children, eye drops and nebuliser solutions are examples of these.

There are a number of situations where the use of preservatives in certain patient populations has been shown to cause adverse reactions and should be avoided. A risk assessment should be undertaken on the use of the preservative in the intended population. There should be evidence of acceptability and safety; absence of evidence of harm should not be taken to mean that a preservative is acceptable.

In addition, for aqueous formulations the risks and benefits of presenting the medicine in either single- or multi-dose containers, with or without an antimicrobial preservative, must be assessed.

Preservative-free Eye Drops

Eye drops are required to be sterile until opened and so preservative-free eye drops must be manufactured as sterile solutions. BP monographs for eye drops are open monographs that do not specify a formulation or a concentration and so will apply equally to preserved and preservative-free preparations. In the absence of a preservative, however, there is a risk of microbiological contamination immediately after the container is opened. Preservative-free eye drops should be for single patient use within one clinical session. The product should be applied immediately after opening and, subject to the above, any remaining solution discarded unless an alternative procedure has been justified and validated.

Preservative-free Oral Liquids

It is widely recognised and accepted that oral liquids for children and neonates should not contain antimicrobial preservatives, if possible. Toxic reactions have been reported to all of the commonly used preservatives. Formulation of oral liquids for children is further complicated by the preference for sugar-free and alcohol-free preparations.

Minimal risk is considered achieved for preservative-free oral liquids if these are presented in single-dose containers, which

have been subjected to a process that renders the contents sterile, and the product is used immediately after first opening. Where this is not possible, appropriate means of preparation, suitable packaging and storage conditions should be defined that achieve and maintain the expected quality of the product throughout its period of use.

In addition, suitable measures should be in place to ensure that users of the product are aware of, and have knowledge of, the optimum procedures for handling and storage of the product in use to minimise the risk of microbial contamination and the subsequent risks to patients.

The following options need to be considered to reduce the risk of microbial contamination during manufacture and the risk of microbial growth and contamination during storage and in use.

To minimise microbial contamination within the product at the time of preparation:

1. Use constituents with low viable counts. Pay particular attention to the microbial quality of water, excipients, containers and closures. The total viable counts of all production batches should be controlled by tight limits that have been justified.

2. Assess the potential for native pathogens to survive and grow in the formulation.

3. Investigate the possibility of sterilisation of the final product. This can lead to problems with stability of the preparations and process validation, especially for more complex formulations, but is often a viable option for less complex formulations.

To minimise microbial growth within the product on storage before first opening:

4. Develop formulations with inherent bactericidal or bacteriostatic properties, for example high osmotic pressure solutions. However, such formulations may irritate the gut and cause nausea/vomiting and have been associated with the development of necrotising enterocolitis in neonates. Consideration may be given to including directions to dilute the preparation with liquid or food immediately before administration and, if acceptable, this should be evaluated.

5. Store in a refrigerator (unless sterile).

To minimise microbial contamination and growth within the product after first opening:

6. Provide the preparation in single-dose containers.

7. Store in a refrigerator.

8. Introduce a suitable expiry time after first opening, supported by appropriate in use testing.

C. Bioequivalence of Oral Liquids

Patients receiving medicines with a low therapeutic index may require their blood levels to be monitored to ensure they remain within the required therapeutic range. This therapeutic drug monitoring is essential for substances such as those used for anticoagulant or neuroleptic therapy, because of the potential for non-bioequivalence between different products, and is particularly important in the case of unlicensed oral suspensions.

Where the medicinal products are licensed, appropriate information will be provided in the Summary of Product Characteristics (SmPC) and/or in the Patient Information Leaflet (PIL). No such information will be provided, however, for unlicensed medicines.

It is possible that different formulations of oral suspensions may not be bioequivalent, particularly if the particle size of the active ingredient in the formulations is significantly different. Differences may occur between batches of the same product from a single source or between formulations from different sources.

For unlicensed oral solutions and suspensions of pharmaceutical substances where bioequivalence is a concern and therapeutic drug monitoring is a routine practice, the following statement has been included in relevant British Pharmacopoeia monographs:

"Patients should be monitored in accordance with appropriate clinical guidelines."

D. Storage and Stability of Unlicensed Medicines

For many unlicensed medicines there will be little or no data on the physico-chemical stability of the formulation that is prepared. By contrast, products with a marketing authorisation are required to have robust and validated stability data to justify their shelf life and storage conditions. Consequently, the assigned shelf life for unlicensed medicines will, in many cases, be based on the professional judgement of the person responsible for its preparation or manufacture, using either available scientific information and published data or a limited amount of stability testing data.

Assigning storage conditions for unlicensed medicines is a complex issue for a number of reasons.

1. Degradation pathways for chemical actives are often complex and are not always predictable.

2. Many unlicensed preparations require the reformulation of solid oral dosage forms as oral liquids or suspensions to facilitate their administration to paediatric and geriatric populations and via naso-gastric tubes. Thus, environmental and physicochemical factors such as heat, light, moisture, and pH will become more critical since, in many cases, very little will be known about the stability profile of the active substance in liquid formulations.

3. Whilst extemporaneous preparations will normally be freshly prepared, the storage and shelf life during use needs to be considered if it becomes impractical to prepare the product each time, immediately prior to dispensing.

4. Excipients such as chemical and microbiological preservatives that prolong the in-use shelf life of products are sometimes deliberately omitted from unlicensed formulations due to the possibility of adverse reactions. This may limit the period over which the product can be stored and used.

5. One of the reasons for the absence of a licensed medicinal product can be that large scale batch manufacture is impractical due to poor stability profiles and hence short shelf life. The product, therefore, becomes uneconomical to manufacture commercially, resulting in the need to prepare an unlicensed version.

6. Whilst it might be possible to produce a stable formulation under suitable controlled conditions prior to use, once the container is opened the risk of degradation can increase significantly, particularly where the in-use storage conditions differ from those applied before opening.

7. The stability of an unlicensed medicine depends not only on the intrinsic stability characteristics of the active substance but also on the influence of formulation excipients and

potential interactions with the packaging components. These factors may be especially complex in cases where a liquid formulation is prepared from a previously formulated solid dosage form.

8. The type and size of the container closure system, and the number of doses it contains, should be consistent with the known stability and dosage regimen of the product.

In the monographs for unlicensed medicines, a storage statement has been included where data on the stability of the formulation are available. Storage statements of the British Pharmacopoeia are non-mandatory but give a recommended shelf life under defined storage conditions. Similarly, where information on the shelf life during use is known, this is also included in the storage statement. As a general rule the information in the storage statement relates only to the physico-chemical stability of the formulation and not to its microbiological quality. Such information applies only to the product formulation described in the monograph. Where a different formulation is used, it cannot be assumed that the storage statement in the monograph will still apply.

Where no storage statement is given in the monograph no assumptions should be made about the stability or shelf life of the product. Pharmacopoeial monographs apply throughout the shelf life of the product and so any assigned storage conditions and shelf life should be validated by the persons responsible for the preparation or manufacture of the product, who should satisfy themselves that the product complies with the monograph during storage and use, and that any assigned shelf life is appropriate.

E. Extemporaneous Preparations

This section provides information and guidance on well-established formulae for widely used unlicensed medicines.

This section includes examples of well-established formulae and/or methods that may be used to prepare a medicinal product extemporaneously. Formulae other than those specified in this section may also be available and the medicinal product may be prepared by other means.

An article intended for medicinal use that is described by means of an official title must comply with the requirements of the relevant monograph, regardless of how it is prepared.

The examples provided have been taken from former fixed strength monographs of the British Pharmacopoeia. These monographs have been amended to an open strength format in order to allow a single monograph to apply to the range of strengths available.

Dithranol Paste

Extemporaneous preparation

Dithranol	1 g, or a sufficient quantity
Zinc and Salicylic Acid Paste	Sufficient to produce 1000 g

Mix the Dithranol with a portion of the Zinc and Salicylic Acid Paste until a smooth, even dispersion is obtained and gradually incorporate the remainder of the Zinc and Salicylic Acid Paste.

Levomenthol Cream

Extemporaneous preparation

Grind the Levomenthol to a *fine powder*. If necessary, a small amount of Glycerol may be added to minimise the creation of airborne menthol dust. Add the Aqueous Cream gradually and mix until smooth.

Salicylic Acid Ointment

Extemporaneous preparation

Salicylic Acid, finely sifted	20 g
Wool Alcohols Ointment	980 g

Melt the Wool Alcohols Ointment, gradually add the Salicylic Acid and stir until cold.

F. Aseptic Preparation of Unlicensed Medicines

This section provides general guidance on the Aseptic Preparation of Unlicensed Medicines. It includes guiding principles that should be followed for all aseptically prepared unlicensed medicines. It also includes specific information relating to Parenteral Nutrition Solutions, Ready-to-Administer Injections and Intraocular Injections.

1. GENERAL GUIDANCE

Introduction

It is now an accepted principle that the aseptic preparation of medicines that are intended for parenteral administration should be undertaken in specialised aseptic preparation units, under the supervision of a pharmacist, and not in clinical areas. The Breckenridge report, published in 1976, recommended centralisation of IV additive services in hospital pharmacy units and the British National Formulary (BNF) supports this advice. There is now a wide range of diverse product types prepared in aseptic units. These can be parenteral nutrition solutions (PN), cytotoxic preparations, radiopharmaceutical injections and additives for parenteral administration. As aseptic preparation services have developed, the benefits of preparing these products in specialised, dedicated facilities has been quickly recognised and the demand for these products has increased. This has led to some standardisation of treatments, enabling batch preparation processes, and as a consequence commercial units operating under Manufacturer's ('Specials') Licences have been developed to meet this demand. Home parenteral nutrition services that supply PN therapy direct to the patients' homes, together with other homecare aseptic therapy services, are a feature of this service development.

The benefits that result from the preparation of these products in specialised facilities are well recognised: dose calculations can be automated or checked and confirmed; products are labelled correctly; documentation allows a treatment audit trail; sterility assurance is increased. There are, however, risks associated with centralisation of aseptic preparation services. Process failures, particularly those that result in product contamination can impact on a wider population compared with individually prepared medicines when a single individual patient is at risk. Furthermore, centralisation of aseptic activities into a small number of specialist facilities can significantly affect capacity and supply. All aseptic units have a finite capacity and increasing supply beyond this capacity, in response to increasing demand, may impact upon product quality and compromise patient safety. It is accepted, however, that the benefits of aseptic preparation in specialised units outweigh the risks and so it is now routine practice.

Aseptic preparation of unlicensed medicines is exempt from the licensing requirements of the Human Medicines Regulations 2012. This includes preparation for individual

patients and the preparation of stocks from which to dispense to patients in accordance with a prescription. Nonetheless, it is expected that aseptic preparation activities for stocks are undertaken in units that possess a Manufacturer's ('Specials') Licence that covers their activities. Aseptic preparation units that are dispensing preparations for individual patients are exempt from these requirements but should be operating in accordance with good practice and appropriate guidance (for example, the NHS guidelines on Quality Assurance of Aseptic Preparation Services[1]).The guidance provided in this Chapter applies to all products prepared aseptically for administration to patients. PN, cytotoxic injections, radiopharmaceuticals and additives for parenteral administration are the most common examples but other dosage forms e.g. irrigations, eye drops, are also applicable.

Patient safety is of paramount importance for aseptic preparation units. Incorrect dosage, inappropriate administration, product degradation, product contamination or lack of sterility can and has caused serious adverse reactions in patients and in some cases has been fatal. Published standards are needed for these high risk products. This should include advice on their safe preparation and the application of current guidelines including, where appropriate, compliance with any general monographs that define analytical requirements.

Standards for Aseptic Preparation Services

The following are the principles that should be followed in order to ensure a comprehensive quality management system (QMS) is implemented for aseptic preparation services that is fit for purpose. There is an abundance of guidance documents that should be referred to for the detail that the QMS should include. These general principles will be the basis for the QMS.

1. FACILITIES

All aseptic manipulations should be performed in a workstation with a controlled workspace environment conforming to EC grade A. This should be sited in facilities that protect and maintain the grade A environment during use and when transferring materials into and out of the workstation. Ideally, clean air devices should run continuously. All rooms and equipment used for aseptic preparation should be cleaned and disinfected regularly. Equipment should have written operating instructions and be part of a planned preventative maintenance programme. The facilities should be commissioned when installed and monitored at regular intervals.

2. FORMULATION AND STABILITY

The range of formulations encountered in aseptic preparation units is very wide and can range from simple two component systems to complex mixtures with in excess of 50 constituents. For a substantial number of these, product stability data is limited or not available. However, an assessment of stability is needed to ensure the quality of the product is suitable for the patient at the time of administration. This assessment should include the chemical and physical stability of the product's components, together with potential incompatibilities with containers and materials used during preparation. Where no assessment of stability can be made, the decision to prepare the product should be made in the context of the clinical needs of the patient, and the shortest possible shelf life that is compatible with the administration procedure and supply logistics should be assigned.

Expiry periods given to products must be evaluated in accordance with local conditions. Data obtained from the literature or from the manufacturer of the products used for the preparation should be carefully assessed to ensure its applicability and validity. As a general principle, the shortest expiry date consistent with the usage pattern of the product should be used.

Microbiological integrity must also form a part of the shelf life assessment.

3. DOCUMENTATION

A comprehensive documentation system should be prepared and approved. These documents should be clear and detailed. They should include standard operating procedures (SOPs) for all the critical activities and functions that will affect the quality of the product. A list of SOPs that should be available can be found in the various guidance documents.

All products that are prepared in the unit should have their own worksheet and labels that ensure product traceability from preparation to administration and identify the person(s) responsible for its preparation and release. Within any one unit, worksheets and labels should have a standardised style and presentation. Batch worksheets should be reproduced from an approved master document. The batch documentation should be sufficiently detailed to allow traceability of starting materials and components to establish an audit trail for the product. Completed worksheets should be retained for a sufficient period to satisfy regulatory requirements. For example worksheets for paediatric medicines should be retained for 30 years.

Operation, cleaning, maintenance and fault logs should be maintained. All Planned Preventative Maintenance (PPM) and breakdown maintenance should be recorded. A permit to work system should be used.

4. PERSONNEL AND TRAINING

An aseptic preparation service must be managed by a person who has up-to-date practical and theoretical experience in aseptic preparation. In unlicensed units this must be a pharmacist. In NHS units the responsible pharmacist is designated as the Accountable Pharmacist. He/she should have practical experience in Good Manufacturing Practice (GMP), formulation of aseptic preparations, validation of aseptic processes and QMS.

All staff working in an aseptic preparation unit should have the knowledge and skills required to perform their duties. A documented training programme should record and confirm the competencies of all staff working in the unit. Staff should not work in the unit until training (or retraining) has been satisfactorily completed. There should be a system of accreditation linked to specific activities for all staff involved in aseptic preparation services.

Media fill trials should be used to validate and confirm the competence of the operators in different aseptic activities.

5. MONITORING

Regular monitoring of the environment, processes and finished products is an essential and fundamental part of the QMS. Standards and guidelines are available for many of the physical and microbiological aspects. Where definitive standards do not exist it is important to set in-house standards and action limits based on meaningful results and monitoring trends.

Senior personnel within the aseptic preparation unit must have an understanding of clean room technology, together with a thorough knowledge of the design and operation of their department e.g. ventilation systems, position and grade of HEPA filters, work stations, etc. A documented programme of monitoring should be in place and should be

adhered to. This will include test limits for environmental monitoring both at rest and in use.

When the unit is in use, the critical zone of the controlled workspace should be monitored continuously.

There should be a planned programme of physical, chemical and microbiological monitoring of finished products to further validate the aseptic processes. Samples may be obtained from unused products, additional samples that are specially prepared, or in process samples taken at the end of the compounding procedure. Sampling of the final container after completion of preparation and prior to issue may be a threat to product integrity and is therefore not recommended.

Media fill trials should be used to validate the process initially and subsequently on a regular basis. These should mirror the batch sizes in the unit and cover the number and types of manipulations performed on the actual batch.

6. CLEANING AND DISINFECTION

All areas of an aseptic preparation unit should be regularly cleaned and, where necessary disinfected, according to written approved procedures and a log kept. Workstations should be cleaned and disinfected before and after each work session and appropriate measures put in place to prevent chemical cross-contamination. The effectiveness of cleaning and disinfection should be routinely demonstrated by microbiological monitoring. The surfaces of all items that are to be used in the grade A workstation should be disinfected by means of swabbing, spraying or immersion prior to their introduction. A sporicidal agent should be used for the transfer process. Gaseous sterilisation of enclosed isolator workstations is also possible.

7. STARTING MATERIALS, COMPONENTS AND CONSUMABLES

Where available, starting materials should be licensed products. Where unlicensed products are used, it is the responsibility of the pharmacist to ensure that the product is of an appropriate quality by means of Certificates of Analysis, analytical testing, or a combination of both, in accordance with appropriate Royal Pharmaceutical and GPhC Specials guidance. Unlicensed materials should be obtained from a supplier with a Manufacturer's ('Specials') Licence. Imported products that are licensed in the country of origin may also be used, subject to appropriate import controls.

Components, including reconstitution devices, syringes and needles, and the product contact parts of filling systems, transfer tubing and final containers, should be purchased sterile from the manufacturer or sterilised prior to use. All such products should be UKCA or CE marked. Components should be packaged in such a way that they can be transferred into the grade A workstation environment without risk of contamination to the product or the environment

8. STORAGE AND DISTRIBUTION

A close examination should be made of all stages between product approval and product use to ensure that the quality of the product is not compromised before its expiry. Distribution should be controlled and validated as rigorously as storage. Where necessary, the security of the cold chain should be assessed and assured. Staff involved in storage and distribution should be aware of their responsibilities and trained appropriately. Distribution records of all products should be kept to ensure that effective recall can take place if necessary.

Management Principles for Aseptic Preparation Units

Aseptic preparation departments must ensure that the products they supply are fit for their intended use and do not place patients at risk. Achieving this objective is the responsibility of senior managers and pharmacy managers and requires the commitment, understanding, and participation of all staff who are involved in the ordering, preparation, storage and supply of aseptic products. Some units may not have the facilities, equipment or competencies to do certain tasks and some products or processes may present too high a risk for the resources available. Appropriate controls are needed to manage this. There must be a comprehensive and correctly implemented QMS. It should be fully documented and its effectiveness monitored. It is the responsibility of the management of the aseptic unit to ensure that standards within the unit are maintained and that any faults or deficiencies, once identified, are rectified.

Senior managers should be aware of current Legislative and Regulatory requirements for aseptic preparation services and ensure that the unit(s) comply with these requirements.

Management of aseptic preparation services should be the responsibility of a named Accountable Pharmacist. Management of day-to-day functions can be delegated but all line-management responsibilities should be defined in the QMS. Senior pharmacy managers and senior managers in the organisation with management accountability for the aseptic preparation service should be familiar with the QMS and support the delivery of safe and effective aseptic products.

The prescribing physician must also understand his/her responsibility for the clinical decision to prescribe an unlicensed medicine and the liability for the efficacy of the product.

1. QUALITY MANAGEMENT SYSTEM

The QMS should fully document the procedures whereby the standards for aseptic preparation outlined above will be applied and achieved. All staff involved in the preparation and supply of aseptically prepared products should have a knowledge and understanding of the QMS and be able to apply it to their areas of work. Evidence of staff competencies in their fields of work should be documented and continuously reviewed. The QMS should be continuously reviewed and the outcome of the review documented and implemented.

All departments undertaking aseptic preparation activities should have a documented organisational structure which indicates clearly the responsibilities and accountability of each member of staff. All staff should be clear about their level of responsibility.

2. PRODUCT APPROVAL

A formal recorded decision of approval should be made by a person authorised to do so before a preparation can be released for use. The person who authorises the approval for use, or his/her deputy, should be suitably trained and have the appropriate knowledge to fulfil this role.

There should be a written procedure for dealing with preparations that fail to comply with the required standard. The investigation should be documented and senior managers informed.

3. CAPACITY PLANNING

Managers must know and document the maximum capacity at which their aseptic preparation units can operate. This will vary depending upon staff resources, the size and design of the unit and storage facilities, but managers need to understand these variables and plan accordingly. No unit should operate at more than 80% capacity for a sustained period. There needs to be sufficient flexibility to accommodate unplanned critical demand. Increasing output

beyond capacity represents a critical risk to the integrity of the product. These decisions to operate at over-capacity are normally taken to minimise costs or increase profits but neither of these reasons are justified at the risk of patient safety. The QMS should define the capacity of the unit and should be constantly updated to reflect changes in staff numbers, staff competencies and facilities.

There should be a contingency plan in place to manage situations when the risk assessment of an over capacity concludes that the risk to product quality, product integrity and patient safety is unacceptable. This should include measures to maintain the supply chain until the capacity of the facilities is restored. The plan should be documented and approved through appropriate management structures and developed with the agreement of pharmacy, medical and nursing staff.

Diversity of supply is also an important aspect of capacity management. Aseptic preparation covers a wide range of product types as evidenced by Section 2 of this chapter. These different product types have different requirements regarding facilities design, equipment, preparation procedures, storage and operator competencies. Activities are not necessarily transferable between units. The capacity for each type of activity should be individually defined in the quality system.

4. INSPECTION AND AUDIT

Internal and external audits should be carried out routinely. Audits should cover all areas where aseptic products are prepared, stored or distributed. They should include examination of documentation, preparation and quality control methods, validation, training and complaints and recall procedures. The Accountable Pharmacist for the unit should take responsibility for all remedial actions.

Internal audits are part of the QMS and should be carried out at regular intervals. An external audit, performed by a suitably trained and qualified person should be undertaken at least every two years.

In the UK, NHS hospitals collaborate in an independent audit programme for aseptic preparation units, which was initiated in 1997. This programme continues and the NHS guidelines for aseptic preparation services provide the standards against which the audits are performed.

2. TYPES OF FORMULATION

2.1 Parenteral Nutrition Solutions

Parenteral Nutrition Solutions are one of the most widely prescribed, and one of the most frequently prepared, unlicensed medicines. Due to the complexity of the formulations, there is only limited routine testing performed on these products. However, the demand for end-product testing is increasing notwithstanding the challenges that sampling of Parenteral Nutrition (PN) solutions presents. The provision of a BP monograph provides a suitable standard for such testing.

Parenteral Nutrition Solutions provide essential nutrition requirements in the form of protein (amino acids), carbohydrate (glucose), and fat (lipids), together with essential elements, trace elements and vitamins.
The composition of PN solutions varies according to the needs of the individual patient with regard to calorific requirements, metabolic status, fluid and electrolyte balance, acid-base status, as well as other specific PN requirements. As a consequence, many are formulated uniquely to the patient's requirements. PN solutions will typically contain the following components:

Amino acids
Glucose
Lipids
Sodium
Potassium
Calcium
Magnesium
Acetate
Chloride
Phosphate
Trace elements (Zn, Cu, Mn, Cr, Se, Fl, I)
Water-soluble vitamins
Fat-soluble vitamins

Antioxidants are not usually added to PN solutions. However, ascorbic acid may be added in doses larger than those required physiologically to act as an antioxidant and to help stabilise the preparation.

The composition of PN solutions will vary significantly depending upon individual patient needs. Requirements for adult PN differ significantly from those for neo-natal and paediatric populations. Therapeutic ranges and established dosage regimens will limit the ranges for the various components, but defining limits is not always possible or practical. The upper range limits of some constituents may be controlled by other factors, such as stability. For example, interaction between phosphate and calcium will cause precipitation above a certain concentration.

STANDARDS FOR PREPARATION

Starting Materials

All starting materials used in the preparation of parenteral nutrition solutions should comply with relevant pharmacopoeial standards (including the monographs for Substances for Pharmaceutical Use and Pharmaceutical Preparations). Licensed preparations should be used, where available. Any unlicensed preparations should have been manufactured in a licensed Specials manufacturing unit in compliance with the conditions of the licence.

Manual Preparation

Due to the complexity of the formulation, and the preparation process, PN should be prepared or manufactured in aseptic preparation facilities. No preparation should be performed in uncontrolled environments and all processes should be automated or semi-automated. Manual preparation carries the greatest risk of error and should only be undertaken in emergency situations.

Automated Systems

Automated compounding devices are routinely used for the preparation of PN solutions. A number of containers can be attached to such devices using specific, single-use tubing. The system's information technology can control the identity of products and components (bar codes), pump flow rates and addition sequence. The systems also incorporate an audit record to facilitate quality checks.

Automation of the preparation process for PN solutions reduces the risk of microbiological contamination since the numbers of manual manipulations are reduced, but increases the risks of reconstitution or mixing errors because when these occur they can affect a wider population. Such errors can arise from:

— Incorrect solutions being used
— Incorrect volumes being set
— Incorrect strength of solutions being used

— Incorrect sequence of addition of solutions
— Inappropriate mixing in the tubing set
— Incompatibilities

Fatalities due to the use of incorrect concentrations of glucose and electrolytes have been reported.

These risks apply equally to manual preparation but are multiplied in automated systems.

Validation of automated filling apparatus should be part of the QMS and should be repeated at appropriate intervals. Process checks should confirm the products and containers are connected correctly.

Incompatibilities

Monovalent cations do not cause physical incompatibility of PN solutions unless they are in high concentrations. Positively charged divalent and trivalent ions neutralise the zeta potential of lipid droplets leading to aggregation, coalescence and phase separation.

Admixture of calcium and phosphate ions in PN solutions may result in the precipitation of calcium phosphate, similarly with magnesium and phosphate. The precipitate will not normally be detected by visual examination in lipid-containing solutions and needs to be prevented by the sequence and rate the ions are added to the solution, the phosphate salt used, the phosphate concentration and the volume of the PN solution. Organic complexes of calcium and phosphate can reduce the risk of precipitation and may be preferred.

It is not appropriate to make further additions to PN solutions. The complexity of the formulation makes assessment of interactions and incompatibilities very difficult. There are reports confirming the use of some additives; these include heparin, insulin, ranitidine and iron, but, in general, all additions should be avoided.

PN solutions are packaged in plastic containers and so container compatibility for PN solutions needs to be considered. Interactions of PN solutions with the surfaces of containers and administration devices can occur. PN solution components can be adsorbed or absorbed to plastics, for example vitamin A is absorbed by PVC bags and tubing. Components of the plastic material can leach into the solution. There are a variety of specialised container-closure systems for use with PN. The most appropriate should be selected for the application concerned. Ethyl-vinyl-acetate (EVA) bags are a better option than PVC, but multilayer bags are now the preferred choice. These provide a barrier to oxygen and therefore have the potential to improve stability.

PN solutions may be supplied in:

— flexible plastic containers with all components admixed in a single container and administered together through an intravenous line;
— a combination of two containers with the lipid emulsion supplied in a separate container. The contents of the two containers are mixed just prior to administration;
— a combination of three containers with the carbohydrate solution, amino acid solution and lipid emulsion provided in separate containers. The contents of the three containers are mixed prior to administration by breaking the separation seals between the three containers.

Stability

The large number of components (up to more than 50) and the metastable lipid emulsion present significant challenges to the stability of PN solutions. Physicochemical reactions that will impact on the stability include:

— Aggregation of lipid droplets; lipid coalescence; phase separation of the emulsion
— Precipitation of calcium phosphate
— Complexation of trace elements
— Oxidation of oxygen-sensitive components
— Chemical degradation of amino acids (glutamine, cysteine)
— Interaction between amino acids and glucose
— Oxidation of lipids, catalysed by trace elements
— Light-catalysed degradation of vitamins

SAFETY CONSIDERATIONS

Aluminium in Parenteral Nutrition Solutions

Aluminium is a polyvalent cation and is found in its ionic form in almost every animal and plant tissue. The general population is exposed to aluminium from a variety of sources including food, water, beverages, canned products, containers and cooking utensils. Exposure to aluminium can also occur through medication such as antacids, buffered analgesics and through parenteral nutrition.

The body has a natural protective barrier to prevent systemic absorption of aluminium. Both skin and lungs are effective in limiting aluminium exposure as is the GI tract. However, these protective mechanisms are bypassed when aluminium is administered parenterally. In adults, 40% of aluminium that is infused intravenously is retained; in neonates, this figure increases to 75%[2]. Aluminium becomes bound to transferrin and albumin and is eliminated via the kidneys. It follows, therefore, that patients with reduced or impaired renal function are at the greatest risk of aluminium toxicity. Premature and neonatal babies who have immature renal function are especially prone to aluminium toxicity.
No current UK guidelines are available on the daily limit for aluminium exposure or aluminium content in parenterals. However, in the US, to limit patients' exposure to aluminium, the Food and Drug Administration (FDA) has restricted the aluminium content of large-volume parenterals for PN to 25 µg/L (but no limit currently exists for small-volume parenterals, although labelling of the aluminium content is required)[3]. Other publications refer to aluminium toxicity following parenteral nutrition, particularly in neonates[4,5]. Aluminium toxicity is more likely to occur in patients with impaired kidney function, including premature infants, who receive parenteral levels of aluminium at greater than 4 to 5 µg/kg/day[5].

The risk of aluminium exposure can increase substantially due to abnormally high levels of aluminium in some parenteral preparations. Calcium Gluconate Injection in glass ampoules is one such product. Calcium Gluconate Injection is routinely used as a source of calcium ions for PN preparations. In September 2010, the MHRA published a Public Assessment Report entitled *"Calcium gluconate injection 10% in 10 mL glass containers: risk of aluminium exposure"*. It reported that, when the aluminium content of Calcium Gluconate Injection 10%, packed in 10 mL (type 1) glass ampoules, was compared to those packed in 10 mL plastic ampoules, there was around 200 times more aluminium in Calcium Gluconate Injection packed in glass ampoules than in that packed in plastic ampoules. Type 1 glass ampoules contain a significant amount of aluminium which may be leached into Calcium Gluconate Injection during autoclaving and storage. As a result of these data, the report made the following recommendations:

1. Do not use Calcium Gluconate Injection packed in small-volume (10 mL) glass containers for repeated or prolonged treatment, including as an intravenous

infusion, in children aged younger than 18 years or in patients with renal impairment;

2. Do not use Calcium Gluconate Injection in small-volume glass containers in the preparation of PN solutions;

3. Use Calcium Gluconate Injection packed in plastic containers to reduce the aluminium burden in vulnerable patients.

High aluminium levels may also be found in other parenteral products used as additives in PN solutions including preparations containing magnesium or containing inorganic phosphates.

2.2 Ready-to-Administer Injections

It is now routine practice to prepare injection solutions in their administration device for direct administration to patients. Examples include intravenous fluid (IV fluid) bags, pre-filled capped syringes and ambulatory infusion pumps. Initially, these were the most commonly reconstituted powders for injection, or cytotoxic doses, but preparation services have now extended to include a wider range of ready-to-use injection solutions. Examples of these include injections supplied as part of a home therapy programme and injections provided in continuous ambulatory infusion devices. A major advantage of preparing these medicines within a properly managed aseptic preparation service is the benefit to patient safety, product quality and operator protection that can be achieved. There are also cost/efficiency benefits in batch preparation of high value medicines such as monoclonal antibodies. These benefits have been detailed in the introductory section of this chapter and so will not be restated. This section will focus on specific aspects of quality and safety that relate to aseptic preparation of injections in a ready-to-administer form. It is recognised that the preparation of injections for immediate administration to patients is also performed by healthcare professionals outside the aseptic preparation unit as a part of their routine duties and in accordance with the Summary of Product Characteristics (SmPC). These will normally be single-dose injections that are administered immediately after preparation and are not intended to be stored for any length of time prior to administration. This chapter is intended for aseptic preparation units where products are prepared in anticipation of demand and are stored in a ready-to-administer form until administered to the patient(s).

Standards for Preparation

Starting Materials

All materials used for the preparation of the injections must be sterile licensed medicinal products. This applies to all injection products, diluents and diluent aids that may be used. In the UK aseptic manipulation of unlicensed materials or any non-sterile solutions is considered as part of manufacturing operations and, as such, must be undertaken in a facility holding an appropriate manufacturing licence.

All administration devices used for the preparation of the injection must be sterile and carry the appropriate UKCA or CE mark. Since the injections are in a ready-to-administer form, the injection device is also the container for the product in its final presentation. Therefore, it must be able to maintain the chemical and microbiological integrity of the product throughout the assigned shelf life. Container integrity must be validated for the intended shelf life of the product in accordance with NHS guidance[6].

All devices and equipment that are used for the manipulation of the product during the aseptic preparation process, and that come into contact with the product, must be sterile and carry the appropriate UKCA or CE mark. This includes any devices used for preparing and transferring the injection from its original formulation into the final container for administration.

Preparation

Generally, preparation of ready-to-administer injections will be a manual operation. Economies of scale are possible where multiple injections can be prepared from the same container, for example in paediatric medicine or where bulk products that allow the preparation of multiple injections from one container are available, but these situations are relatively rare. For the majority of these injections, manual manipulation has been the norm.

This is changing with the introduction of automated filling systems and robotic systems for the aseptic preparation of injections. Robotics allow batch preparation of a single product on a large scale but can also be used to prepare individual single patient doses. Robotics reduce the need for manual manipulations and so should improve sterility assurance of the process. Batch processing does, however, increase the size of the population at risk in the event of process failure and so suitable controls should be in place to mitigate this. These will include validation of the precision and accuracy of the robotics operation.

Preparation can be a simple process of transferring a sterile solution from one container to another or a more complex process involving reconstitution, dilution, mixing and transfer. Protocols for the training and validation of staff and for process validation should cover the full range of products and processes used in the aseptic preparation unit. Current published guidance on standards for aseptic preparation services should be followed.

Batch Preparation

Ready-to-administer injections will be unit dose presentations. However, there are circumstances where the preparation process produces multiple doses from the same injection container, or more than one injection of the same product is prepared as a single batch process from a number of individual containers. Batch sizes can vary from 5-1000.

Although multiple preparations of injections from single containers are considered as batch processes in the context of aseptic preparation, within each batch the value of the quality attributes for individual injections may vary. Within any batch of licensed dry powder injection, the amount of active ingredient will vary, within approved limits, and so the concentration of the active ingredient in any batch of reconstituted prepared injections will be different. This is the reason why setting meaningful limits for the concentration of active ingredient in unlicensed medicines prepared from dry powder licensed products is difficult and must allow for the uniformity of dose variation in the licensed product. Furthermore, where the transfer of the injection into its final container is a manual procedure, the sterility assurance for each container within the batch will differ. Microbiological data from a single container cannot be extrapolated to the rest of the batch. It is for this reason that sterility tests should be performed as part of an on-going quality assurance programme rather than a product quality control test.

Dose banding of cytotoxic injections has been specifically introduced to allow batch preparation of these injections rather than individual preparation of specific patient doses. For safety reasons cytotoxic injections should, as a minimum, be prepared in a Class 2 safety cabinet or a negative pressure isolator. Positive pressure isolators with demonstrable low leakage rates are available, but need to be safely validated.

Preparing individual patient doses for busy clinics creates a heavy workload which can affect product quality and patient safety. Dose banding regimes allow preparation and storage in advance of its use. However, it introduces issues with stability and compatibility and integrity associated with the storage of the injection. National NHS specifications for dose-banded cytotoxic injections are available[7].

Incompatibilities

Solutions of injections will usually be salts of weak acids or bases. Others, like high molecular weight proteins, will contain weak acid or base moieties. They are presented in solution at a pH which maintains the physicochemical stability of the injection and any change to the solution pH will affect the solubility and stability of the injection components. This applies both to the active ingredient and to any excipients.

Injections should be prepared as single component solutions. Admixtures to form multiple product solutions in their final container will affect the pH equilibrium and should be avoided, due to the risk of both physical and chemical instability. Nonetheless, admixtures are a convenient means of administering multiple drugs and their use is increasing in cytotoxic therapy (eg. vincristine and doxorubicin) and in other commonly used drug combinations (e.g. fentanyl and bupivacaine). In circumstances where multiple component solutions are prepared, a full evaluation of the stability and compatibility of the admixture must be performed. This should include particle size analysis, including sub-visible particles.

Injection solutions can also be incompatible with the administration device and tubing used to administer them and it is advised to refer to information in the SmPC of the licensed product. Licensed injections are normally supplied in glass containers whereas the administration device will be plastic or rubber. Absorption or adsorption of the active ingredient onto the administration system is possible and can result in the dose being reduced. Absorption is most prevalent with PVC bags and tubing and, where absorption does occur, the high surface area to volume ratio of the narrow bore connective tubing will increase the degree of absorption.

Leaching of extractable plastic components of containers and administration devices may also be a potential source of product contamination and be a risk to patient safety. This will be particularly pertinent when storage times in administration devices are extended beyond licenced recommendations. Assessments of administration devices should take account of assigned shelf lives and storage conditions and consider the potential leaching of contaminants into the injection solution.

Stability

Shelf lives for injections in ready-to-use preparations need to be based on both the physicochemical stability of the active ingredient(s) and critical excipients, and the microbiological stability of the final product. Dry powder injections are usually formulated as such because of their instability in solution. Furthermore, the product SmPC contains recommendations on the stability and shelf life of injections after preparation and advises that, following preparation, the product should be used immediately. Extending the shelf life beyond these recommendations transfers liability for the quality and safety of the product to the user. If aseptic preparation services are to operate economically, they must be able to assign shelf lives that are relevant to the required storage and use of the product. Suitable shelf lives may be assigned to enable effective provision of the service. This may be longer than the SmPC recommendations, but should not exceed 7 days unless justified. All shelf lives for prepared injections should be based upon robust validated data. Peer reviewed published data can be used but, in the absence of this, in-house studies should be performed. NHS standards for the assessment and conduct of stability studies are now available[8,9].

The physicochemical stability of injection solutions is dependent upon a number of individual and interacting factors, which should be taken into account during stability studies and assignment of shelf life. These factors include, but are not limited to:

- *Chemical stability in solution* Injections that are presented as aqueous solutions in their licensed formulation are stable to the end of their assigned shelf life, when stored in their original container, and are demonstrated as such through the licensing process. On the other hand, stability profiles for reconstituted dry powder injections will vary significantly. Once removed from its licensed packaging, and manipulated to prepare a ready-to-use injection, the product composition will be altered and the licensed shelf life will not be applicable.
- *Concentration* Dilution of the active ingredients can affect their stability profile and increase degradation rate. Excipients such as solubilising agents and antimicrobial preservatives can become less effective.
- *Oxygen* Many injections are presented in oxygen-free containers. Preparation introduces oxygen into the solution which may significantly affect the stability.
- *Light* Products that are sensitive to light will be protected from light in their licensed packaging. This may not apply to the packaging for injections in their ready-to-use form.
- *Temperature, Storage, Administration* Following preparation, ready-to-use injections should be stored at 2-8°. There will be circumstances where this is either not possible or is inappropriate. In these cases, suitable storage should be defined and supported by evidence. During administration, the temperature will increase. This will rise to room temperature for some devices and for continuous infusion pumps worn next to the body this will be nearer to body temperature. Stability testing protocols should take account of this variation and the time outside refrigerated storage. Current regulatory advice is to conduct stability studies for body-worn devices at 32°.
- *pH* Aqueous solutions of injections are generally unbuffered. Altering the pH of the solution can affect both the chemical and the physical stability of the product; solubility can be reduced and degradation rates can change. Such changes can occur when using multi-component injection admixtures or can be due to the dilution vehicle used for its preparation. This should be considered during formulation development.

Microbiological stability refers to the ability to maintain the microbiological integrity of the product from its preparation to the point of its administration. Where the product has been prepared in a controlled and validated aseptic preparation unit, quality assurance programmes should provide guarantees of product sterility at the point of release. No aseptic process will be 100% effective but, for aseptic preparation, sterility assurance levels of at least 10^{-3} would be expected. During storage, the sterility of the preparation will be determined by the integrity of the container-closure

system and the storage conditions. These should have been validated.

For cytotoxic preparations, information on the stability of preparations is published in The Handbook of Cytotoxic Medicines[10]. Part 1 of the Handbook is a series of chapters on best practice for cytotoxic preparation services and Part 2 contains monographs on injectable cytotoxic medicines used in cancer chemotherapy. The objective of the monographs was to provide the user with information on the preparation, administration and stability of cytotoxic injections and so enable a valued judgement on the use of these products. In addition to sections on the chemistry, clinical use and preparation of injections there was a section on the stability profile of the products. This was a summary of the known stability profile including degradation pathways, parameters that influence stability after reconstitution and packaging, incompatibilities, and container compatibilities. Although some of the information in the Handbook is no longer current, it remains a reference point for those products covered by the monographs.

2.3 Intraocular Injections

Intraocular injections include intracameral injections that are administered into the anterior chamber of the eye and intravitreal injections that are administered into the vitreous chamber of the eye. They also encompass sub-retinal injections, corneal injections and intravitreal implants, but these are outside the scope of the current chapter. Due to the unique physiological composition of the eye, intraocular injections have very specific requirements that would not necessarily apply to other parenteral preparations. It is important to recognise these differences and to apply quality standards that are appropriate and achievable.

Intraocular injections must be free from preservatives and from excipients that may cause toxicity to the corneal epithelium, endothelium, lens or the retina.

Endotoxin levels, osmolality, isotonicity and pH are particularly critical in these preparations.

PREPARATION

Preparation may involve manufacture from active pharmaceutical ingredients or preparation from licensed medicinal products, often followed by several dilution stages. Preservative-free diluents should be used at all stages of preparation. The diluent used will influence the osmolality and pH of the final preparation, which should comply with the requirements for Intraocular Injections stated under the General Monograph for Unlicensed Medicines.

When withdrawing solutions from glass ampoules, a suitable filter needle should be used to prevent spicules of glass entering the preparation.

DOSE

Intracameral Injections

Intracameral injections are administered into the aqueous humour, which has a volume of 200 to 250 microlitres in adults. Volumes of 0.1 mL are usually administered. A volume of 0.1 mL is routine for administration that is left *in situ* but larger volumes may be administered during surgical procedures.

Intravitreal Injections

Intravitreal injections are administered into the vitreous humour, which has a volume of 4 mL in adults. Volumes of 0.05 to 0.1 mL are administered, although 0.2 mL may be administered in vitrectomised eyes.

It may be necessary to adjust the dose in paediatric patients due to the smaller volume of the vitreous humour in such patients.

CONTAINER

Intraocular injections must be supplied in single-dose containers. Silicone-free syringes are recommended. A pre-filled Luer lock syringe with a blind hub should be used, preferably double wrapped. A sterile double wrap is preferred, particularly for use during surgery.

Supplementary Chapter VI

Pharmacopoeial Quantitative Analysis

A. Pharmacopoeial Calculations

Introduction

This Chapter provides information on methods of calculating numerical limits specified in monographs of the British Pharmacopoeia. To facilitate calculations, information on Weights and Measures is included in Appendix XXIII.

The presentation of this Chapter follows the order in which the tests appear in monographs for medicinal substances and formulated preparations. The calculations will apply where techniques are common for tests and assays. Examples provided are those specified in the British Pharmacopoeia, with varying degrees of complexity.

The majority of pharmacopoeial calculations use the ratio of the measured sample response (that is, peak area, titration volume, UV absorbance, etc) to the standard response (measured, stoichiometric or a fixed value).

LIMIT TESTS FOR ANIONS

Limit tests for anions are usually specified in parts per million(ppm) in British Pharmacopoeia monographs unless the limit exceeds 500 ppm in which case the limits are expressed in per cent weight in weight (% w/w).

The key to determining the nominal limit set in the test is to calculate the weight of the sample in the same volume as the standard solution and convert this to µg per g. It is also helpful to associate parts per million in terms of the number of µg of the impurity being limited perg of substance being examined.

The standard solutions used as reference standards in limit tests for anions are published in Appendix I C and their concentrations are expressed in ppm. These concentrations may more conveniently be considered in terms of µg per mL so that the calculations are made in the same numerical value or units and are based on the assumption that 1 g is approximately equivalent to 1 mL in dilute aqueous solutions since the density of water is about 1.0 g per mL.

For example, in the Limit Test for Chlorides (Appendix VII), the standard solution contains 50 µg of Cl (10 mL of 5 ppm Cl). Thus, if the sample solution contains 1g of the substance being examined in the same volume as the standard solution, the limit being set is 50 µg per g, that is, 50 ppm.

As an illustration of the above, in the monograph for Aluminium Glycinate, the test for Chlorides is as follows.

Dissolve 1.0 g in 10 mL of 2M *nitric acid* and dilute to 100 mL with *water*. 15 mL of the resulting solution complies with the limit test for chlorides, Appendix VII (330ppm).

To calculate the limit, determine the actual weight of the substance being examined. In the above example, it is:

(15 ÷ 100) × 1.0 (the original weight taken for the test) = 0.15 g.

This gives a sample weight of 0.15 g.

In order to compare like with like, 15 mL of the standard solution in the limit test for Chlorides contains 10 mL of a 5 ppm chloride solution equivalent to 50 µg of Cl. Therefore 1 g of the substance being examined contains:

(1 ÷ 0.15) × 50 = 333.33 µg (nominally 330 ppm).

An illustration of how to calculate the limit in tests where no value is specified is given below using the test for Inorganic phosphates in the monograph for Hydrocortisone Sodium Phosphate.

Inorganic phosphate Dissolve 25 mg in 10 mL of *water*, add 4 mL of 1M *sulfuric acid*, 1 mL of a 10% w/v solution of *ammonium molybdate* and 2 mL of *methylaminophenol-sulfite reagent* and allow to stand for 15 minutes. Add sufficient *water* to produce 25 mL and allow to stand for a further 15 minutes. The absorbance of a 4-cmlayer of the resulting solution at 730 nm, Appendix II B, is not more than that of a 4-cm layer of a solution prepared by treating 10 mL of a 0.0036% w/v solution of *potassium dihydrogen orthophosphate* in the same manner, beginning at the words 'add 4mL ...'.

As a first step, determine the percentage content of phosphate(PO_4) in potassium dihydrogen orthophosphate (KH_2PO_4) using the atomic weight of phosphate (PO_4) (P + O_4; i.e. 30.97 + 64.00 = 94.97) and the molecular weight of KH_2PO_4(136.10). Thus:

$$(94.97 \div 136.1) \times 0.0036 = 0.0025$$

0.0036% w/v of potassium dihydrogen orthophosphate is equivalent to 0.0025% of phosphate. Therefore 10 mL of a 0.0036% w/v solution contains 0.00025 g of phosphate.

Ensure that the weights for comparison purposes are in the same units. Therefore, convert the sample weight (25 mg) to grams. Thus:

$$25 \div 1000 = 0.025$$

The sample solution contains 0.025 g in 10 mL.

To calculate the percentage limit, use the values obtained above, compare the weight of the standard solution with the weight of the sample and multiply by 100. Thus:

$$(0.00025 \div 0.025) \times 100 = 1\%$$

LIMIT TESTS FOR CATIONS

The principles for determining the limit for anions apply when determining the limit for cations. The following example is taken from the European Pharmacopoeia monograph for Bismuth Subcarbonate.

Silver To 2.0 g add 1 mL of *water R* and 4 mL of *nitric acidR*. Heat gently until dissolved and dilute to 11 mL with *waterR*. Cool and add 2 mL of 1M *hydrochloric acid*. Allow to stand for 5 min, protected from light. Any opalescence in the solution is not more intense than that in a standard prepared at the same time in the same manner using a mixture of 10 mL of *silver standard solution (5 ppm Ag) R*, 1mL of *nitric acidR* and 2 mL of 1M *hydrochloric acid* (25 ppm).

In the reference solution, 10 mL of 5 ppm Ag is specified. This is equivalent to 10 mL of a 5 ppm solution:

$$5 \times 10 = 50\ \mu g$$

50 µg in 2 g is 25 µg per gram which is 25 ppm.

The limit is calculated by dividing the maximum amount of Ag permitted inmg by the weight of the sample taken in mg and multiplying this by 1000000. Thus:

$$(0.05 \div 2000) \times 1\,000\,000 = 25\ ppm$$

Note that, as a check, the calculated 'weight equivalent' of the limit in ppm should be the same as the calculated weight of impurity present in the reference solution.

RELATED SUBSTANCES

The key to determining the nominal limit set in the test is to compare the absolute concentrations (e.g. in mg/mL or % w/v) of the test solution and the limiting solution. The relative concentration may then be calculated as a percentage and this gives the limit.

Examples below are based on the various chromatographic techniques used in British Pharmacopoeia monographs.

1. The following test is included in the monograph for Choline Theophyllinate.

Carry out the method for *thin-layer chromatography*, Appendix III A, using *silica gel* HF_{254} as the coating substance and a mixture of 95 volumes of *chloroform* and 5 volumes of *ethanol (96%)* as the mobile phase. Apply separately to the plate 5 µL of each of two solutions of the substance being examined in *ethanol(96%)* containing (1) 1.0% w/v and (2) 0.010% w/v. After removal of the plate, allow it to dry in air and examine under *ultraviolet light (254 nm)*. Any secondary spot in the chromatogram obtained with solution (1) is not more intense than the spot in the chromatogram obtained with solution (2) (1%).

To calculate the nominal limit, compare the concentration of the limiting solution with the test solution prescribed and multiply by 100 to obtain the percentage content of related substances permitted. Thus, for the above example, the calculation is as follows:

[Concentration of solution (2) ÷ Concentration of solution (1)] × 100

$$(0.010 \div 1) \times 100 = 1\% = \text{nominal limit}$$

2. The example below is an extract from the British Pharmacopoeia monograph for Ethanolamine.
The chromatographic conditions included in the monograph are not reproduced below.

Prepare a 0.1% w/v solution of *3-aminopropan-1-ol* (internal standard) in *dichloromethane* (solution A). Carry out the method for *gas chromatography*, Appendix III B, using the following solutions prepared in suitable sealed reaction vials. For solution (1) prepare a solution containing 0.05% w/v of ethanolamine and 0.1% w/v each of *diethanolamine* and *triethanolamine* in solution A. To 0.5 mL of this solution add 0.5 mL of *trifluoroacetic anhydride*, mix and allow to stand for 10 minutes. For solution (2) prepare a 10% w/v solution of the substance being examined in solution A. To 0.5 mL of this solution add 0.5 mL of *trifluoroacetic anhydride*, mix and allow to stand for 10 minutes.

In the chromatogram obtained with solution (1) the peaks eluting after the solvent peak in order of emergence are due to (a) ethanolamine, (b) 3-aminopropan-1-ol, (c) diethanolamine and (d)triethanolamine. In the chromatogram obtained with solution (2) calculate the content of diethanolamine and triethanolamine by reference to the corresponding peaks in the chromatogram obtained with solution (1). Calculate the content of any other impurity by reference to the peak due to ethanolamine in the chromatogram obtained with solution (1). The content of diethanolamine and triethanolamine is not more than 1.0% w/w of each, the content of any other impurity is not more than 0.5% w/w and the sum of the contents of all the impurities is not more than 2.0% w/w.

The limits are expressed in exactly the same way as previously, by comparing the absolute concentrations of the impurities in solution (1) to the concentration of solution (2). Thus:

For ethanolamine:

$$(0.05 \div 10) \times 100 = 0.5\%$$

For diethanolamine and triethanolamine:

$$(0.1 \div 10) \times 100 = 1\%$$

However, as this method includes an internal standard, the ratios of the peak areas of the impurity and the internal standard are determined before the results are calculated.

3. The following example is taken from the British Pharmacopoeia monograph for Amantadine Capsules.
The chromatographic conditions included in the monograph are not reproduced below.

Carry out the method for *gas chromatography*, Appendix III B, using 1 µL or other suitable volume of the following solution. Dissolve a quantity of the contents of the capsules containing 0.1 g of Amantadine Hydrochloride in 2 mL of *water*, add 2 mL of a 20% w/v solution of *sodium hydroxide* and 2 mL of *chloroform* and shake for 10 minutes. Separate the chloroform layer, dry over *anhydrous sodium sulfate* and filter.

The area of any secondary peak is not greater than 0.3% and the sum of the areas of any secondary peaks is not greater than 1% by normalisation.

The impurity content in the above example is determined by normalisation. The percentage content of any secondary peak is calculated by determining the area of the peak as a percentage of the total area of all the peaks, excluding those due to solvents or any added reagents.

$$\%\ \text{Impurity} = [(\text{Impurity response}) \div (\text{total responses})] \times 100$$

4. The following example is taken from the British Pharmacopoeia monograph for Lormetazepam.
The chromatographic conditions included in the monograph are not reproduced below.

Carry out the method for liquid chromatography, Appendix III D, using five solutions in *methanol (70%)* containing (1) 0.25% w/v of the substance being examined, (2) 0.0005% w/v of the substance being examined, (3) 0.00025% w/v of the substance being examined, (4) 0.0005% w/v of *lormetazepam BPCRS* and (5) 0.00025% w/v each of *lormetazepam BPCRS* and *lorazepam BPCRS*.

In the chromatogram obtained with solution (1) the area of any *secondary peak* is not greater than that of the principal peak in the chromatogram obtained with solution (2) (0.2%) and not more than two such peaks have an area greater than the area of the principal peak in the chromatogram obtained with solution (3) (0.1%). The sum of the areas of all such peaks is not greater than 2.5 times the area of the principal peak obtained with solution (2) (0.5%).

To calculate the first limit, compare the concentrations of the two solutions specified, that is, solutions (1) and (2) and multiply by 100 to obtain the percentage limit. Thus:

[Concentration of solution (2) ÷ Concentration of solution (1)] × 100%

$$(0.0005 \div 0.25) \times 100 = 0.2\%$$

For the second limit, compare the concentrations of the two solutions specified, that is, solution (1) and (3) and multiply by 100 to obtain the percentage limit. Thus:

[Concentration of solution (3) ÷ Concentration of solution (1)] × 100%

$$(0.00025 \div 0.25) \times 100 = 0.1\%$$

For the third limit, the value obtained for the first limit multiplied by 2.5 will give the sum. Thus:

$$0.2 \times 2.5 = 0.5\%$$

Note that certain solutions specified within the test are not used to calculate the limits but are used for system suitability purposes.

COMMON SOLVENTS AND OTHER RESIDUES

The following example is taken from the British Pharmacopoeia monograph for Azapropazone.

Acetic acid Not more than 0.2%, determined by the following method. Dissolve 10 g in 25 mL of *methanol*, add 75 mL of *water* and carry out a *potentiometric titration*, Appendix VIII B, using 0.1M *sodium hydroxide VS* as titrant to a pH of 5.9. Each mL of 0.1M *sodium hydroxide VS* is equivalent to 6.005 mg of acetic acid, $C_2H_4O_2$.

The formula to calculate the result is as follows:

$$[V \times (6.005 \times C / 0.1) / w] \times 100$$

V = the volume used (mL)

C = the exact molarity of *sodium hydroxide VS*

w = weight in mg of the substance being examined

RESIDUE ON IGNITION

The following example is taken from the British Pharmacopoeia monograph for Calamine.

68.0 to 74.0%, when ignited at a temperature not lower than 900° until, after further ignition, two successive weighings do not differ by more than 0.2% of the weight of the residue. Use 1 g.

To calculate the percentage Residue on ignition in the example above, the formula to use is as follows.

$$[(w_1 - w_2) / (w_3 - w_2)] \times 100$$

w_1 = weight in g of the ignited crucible and residue

w_2 = weight in g of the crucible

w_3 = weight in g of the crucible and sample

B. Titrimetric Analysis

This Supplementary Chapter provides general guidance regarding the practice of titration in quantitative pharmaceutical analysis. It is not intended as an exhaustive guide to the underlying theory.

Basic concepts

Titration is the process of dissolving an analyte and reacting with another species in a solution of known concentration (titrant). Once the reaction between the analyte and the titrant is well understood, the stoichiometry is characterised and the point at which the titrant amount is equivalent to the analyte amount (the equivalence point) is known, the exact quantity of the analyte can be determined by simple calculation.

Acid-base titrations The determination is based on the neutralisation reactions that occurs between an acid and a base. A measured volume of an acid or base of known concentration is reacted with a sample to the equivalence point. The relative acidity (basicity) of an aqueous solution can be determined using the relative acid (base) equivalents. An acid equivalent is equal to one mole of H^+ ions. Similarly, a base equivalent is equal to one mole of OH^- ions. Some acids and bases are polyprotic, which means that each mole of the acid or base is capable of releasing more than one acid or base equivalent. Examples of monoprotic acids are hydrochloric acid (HCl) and nitric acid (HNO_3). Examples of polyprotic acids are sulfuric acid (H_2SO_4) and phosphoric acid (H_3PO_4).

When the solution of known concentration and the solution of unknown concentration are reacted to the point where the number of acid equivalents equals the number of base equivalents (or vice versa), the equivalence point is reached. The equivalence point of a strong acid or a strong base will occur at pH 7. For weak acids and bases, the equivalence point need not occur at pH 7. There will be several equivalence points for polyprotic acids and bases.

Redox titrations The determination is based on the transfer of electrons between a donor (reducing agent) and an acceptor (oxidising agent). During the reaction, the oxidising ion, whether it is the analyte or the titrant, is reduced by gaining one or more electrons and the reducing ion is oxidised, losing one or more electrons.

These reactions are less common than acid/base reactions but involve a wider range of titrants including oxidising agents (such as iodine, potassium dichromate, potassium permanganate solutions, cerium(IV) salts, hydrogen peroxide, oxidised chlorine (for example ClO^-, ClO), and reducing agents (such as sodium thiosulfate, oxalic acid, ammonium iron(II) sulfate ("Mohr's salt"), hydrogen peroxide, phenylarsine oxide).

Complexometric titrations The determination is based on the formation of a complex usually between a chelating agent and a metal cation. The most frequent use of complex reactions is to determine the concentration of divalent cations such as calcium, magnesium, copper, lead, zinc and cadmium as well as other cations such as aluminium.

The most commonly used complexing reagents are ethylenediaminetetraacetic acid (EDTA) and ethylenebis (oxyethylenenitrilo)tetracetic acid (EGTA).

Although these reactions are easy to perform, it is necessary to work within a well-defined pH interval.

Precipitation titrations The determination is based on the formation of an insoluble salt under certain conditions. During a titration, the end of the precipitation reaction means that excess titrant is present and a coloured complex appears immediately. They are performed in slightly acidic conditions (pH about 4.5) and solvents such as ethanol or acetone may be added to reduce the solubility of the precipitate.

The most frequent use of precipitation reactions in analytical chemistry is the titration of halides (in particular chloride ions) with silver ions.

Direct titrations

In a direct or forward titration the analyte reacts directly with the titrant. For example, a known volume of a solution of unknown acidity may be titrated with a base of known concentration until complete neutralization has occurred. This point is called the equivalence point and is generally determined by observing a colour change in an added

indicator such as phenolphthalein. From the volume and concentration of added base and the volume of acid solution, the unknown concentration of the solution before titration can be determined.

Titrations can also be used to determine the number of acidic or basic groups in an unknown compound. A specific weight of the compound is titrated with a known concentration of acid or base until the equivalence point has been reached. From the volume and concentration of added acid or base and the initial weight of the compound, the equivalent weight, and thus the number of acidic or basic groups, can be determined.

Examples of direct titrations include the Assay for Fusidic Acid and the Assay for Ketoconazole.

Back titrations

The term back titration is used when a titration is done "backwards"; instead of titrating the original analyte, a volumetric solution of a reagent is added to the solution to react with the analyte, then the excess reagent is titrated.

Back titrations are useful if the end point of the reverse titration is easier to identify than the end point of the normal titration. They are also useful if the reaction between the analyte and the titrant is very slow. They may also be used where direct titrations are unsuitable for technical reasons, including: when the sample is not soluble in water, or when the sample contains impurities that interfere with forward titration.

Examples of back titrations include the Assay for Aspirin Tablets and the Assay for Cloxacillin Benzathine.

Measuring the equivalence point

The equivalence point may be determined in a number of ways. The most common is the use of an indicator that shows a colour change at the equivalence point.

Alternatively, the pH or potential difference of the solution can be plotted against the amount of added acid or base on a graph; such a plot is called a titration curve and is usually sigmoid (S-shaped), with the inflection point where the curve changes direction corresponding to the equivalence point. From the pH at the equivalence point, the dissociation constant of the acidic or basic group can be determined. If a compound contains several different acidic or basic groups, the titration curve will show several sigmoid-shaped curves and the dissociation constant of each group can be obtained from the pH at its corresponding equivalence point.

Indicators

Indicators are used to provide a visual determination of the end point of a reaction. This may be by a change in colour or the formation of a precipitate.

Because they are used in low concentrations, indicators do not appreciably alter the equivalence point. Sometimes the volume difference (error) is ignored; in other cases a correction factor may be applied. Often a sensitivity test may be used as a suitability check before an indicator is used.

Examples of indicators where sensitivity tests are specified include Methyl Orange Solution, Phenolphthalein Solution, Starch Solution and Thymol Blue Solution.

Acid/base Indicators Acid-base indicators are weak acids or weak bases. The undissociated form of the indicator has a different colour to the dissociated form. Indicators do not change colour from pure acid to pure alkali at a specific hydrogen ion concentration; rather the colour change occurs over a range of hydrogen ion concentrations. This range is often termed the *colour change interval* and is expressed as a pH range.

Acid-base indicators include Bromocresol Green, Cresol Red, Crystal Violet, Methyl Orange, Phenolphthalein and Thymol Blue.

An example of this type of titration is the Assay for Aspirin Tablets.

Redox indicators Redox indicators undergo a definite colour change at a specific electrode potential. As they have different colours in their oxidised and reduced states, their colour changes according to the redox potential of the solution. As for those used in pH measurement, these indicators have specific *colour change intervals* expressed in mV. They may be dependant or independent of pH.

Redox indicators include Nitrophenanthroline, Diphenylamine, Indigo Carmine, Methylene Blue and Ferroin.

An example of this type of titration is the Degree of unsaturation test in the monograph for Undecenoic Acid.

Complexometric indicators Complexometric indicators are ionochromic dyes that undergo a definite colour change in the presence of specific metal ions. They form a weak complex with the ions present in the solution, which has significantly different colour than the uncomplexed form. They are also called metallochromic indicators.

Complexometric indicators are water-soluble organic molecules, including Eriochrome Black T, Xylenol Orange, Murexide, Eriochrome Blue SE, Methylthymol Blue and Naphthol Green B.

An example of this type of titration is the Assay in the monograph for Hydrotalcite Tablets.

Precipitation indicators Precipitation indicators precipitate from solutions in a readily visible form at or near the equivalence point of a titration.

Precipitation indicators include Fluorescein and Eosin.

The *colour change intervals* for several common indicators are given in Supplementary Chapter VI C.

C. Indicator Colour Changes

This Supplementary Chapter provides a list of colour change intervals for some common indicators, with approximate pKa values and colours. It is provided for the convenience of the analyst in selecting appropriate indicators for their applications. Values given are approximate and are the modal or median averages of several reported figures. Where "not reported" is stated the value has not been reported in the sources consulted in the compilation of the list.

ALIZARIN S

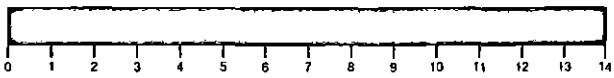
Approximate pKa: not reported

Approximate pH range for colour change: 3.7-5.2

Colour of acid form: yellow

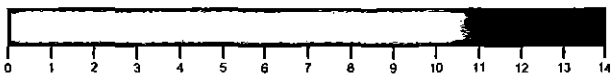
Colour of base form: red

ALIZARIN YELLOW GG



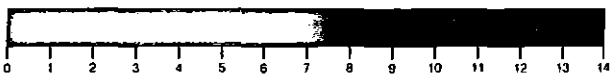
Approximate pKa: 11.0
Approximate pH range for colour change: 10.0-12.0
Colour of acid form: clear
Colour of base form: yellow

ALIZARIN YELLOW R



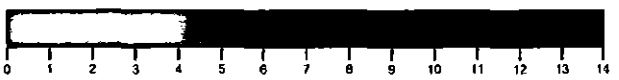
Approximate pKa: 11.0
Approximate pH range for colour change: 10.1-12.0
Colour of acid form: yellow
Colour of base form: red

BRILLIANT YELLOW



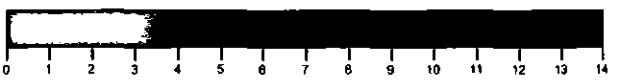
Approximate pKa: not reported
Approximate pH range for colour change: 6.6-7.8
Colour of acid form: yellow
Colour of base form: orange

BROMOCRESOL GREEN



Approximate pKa: 4.7
Approximate pH range for colour change: 3.8-5.4
Colour of acid form: yellow
Colour of base form: blue

BROMOPHENOL BLUE

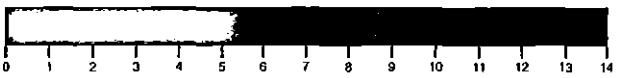


Approximate pKa: 4.0
Approximate pH range for colour change: 3.0-4.6
Colour of acid form: yellow
Colour of base form: blue

BROMOTHYMOL BLUE

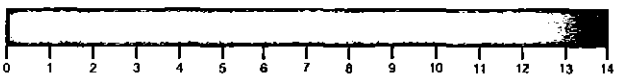
Approximate pKa: 7.1
Approximate pH range for colour change: 6.0-7.6
Colour of acid form: yellow
Colour of base form: blue

CHLOROPHENOL RED



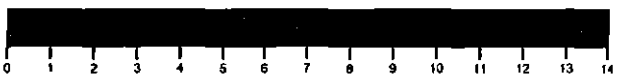
Approximate pKa: 6.0
Approximate pH range for colour change: 4.8-6.4
Colour of acid form: yellow
Colour of base form: red

CLAYTON YELLOW



Approximate pKa: not reported
Approximate pH range for colour change: 12.2-13.2
Colour of acid form: yellow
Colour of base form: amber

CONGO RED

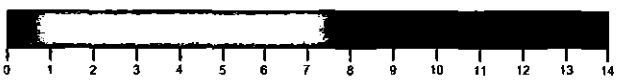


Approximate pKa: not reported
Approximate pH range for colour change: 3.0-5.0
Colour of acid form: blue
Colour of base form: red

CRESOL RED (IN ACID SOLUTION)

Approximate pKa: not reported
Approximate pH range for colour change: 0.0-1.0
Colour of acid form: red
Colour of base form: yellow

CRESOL RED (IN BASIC SOLUTION)

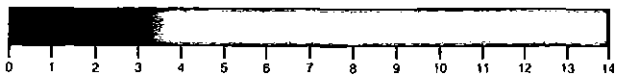


Approximate pKa: not reported
Approximate pH range for colour change: 7.2-8.8
Colour of acid form: yellow
Colour of base form: red

CRYSTAL VIOLET

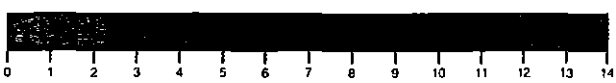
Approximate pKa: 0.8
Approximate pH range for colour change: 0.0-2.0
Colour of acid form: yellow-green
Colour of base form: blue

DIMETHYL YELLOW



Approximate pKa: 3.3
Approximate pH range for colour change: 2.9-4.0
Colour of acid form: red
Colour of base form: yellow

ERYTHROSINE (DISODIUM SALT)

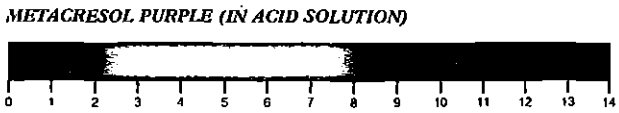


Approximate pKa: not reported
Approximate pH range for colour change: 2.2-3.6
Colour of acid form: orange
Colour of base form: red

MALACHITE GREEN

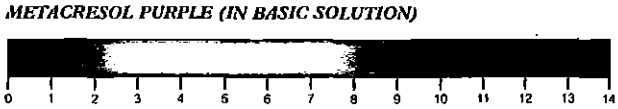
Approximate pKa: 1.0
Approximate pH range for colour change: 0.2-1.8
Colour of acid form: yellow
Colour of base form: blue-green

METACRESOL PURPLE (IN ACID SOLUTION)



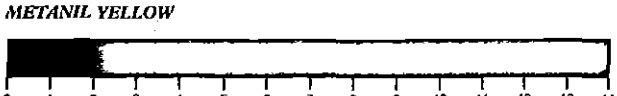
Approximate pKa: 2.0
Approximate pH range for colour change: 1.2-2.8
Colour of acid form: red
Colour of base form: yellow

METACRESOL PURPLE (IN BASIC SOLUTION)



Approximate pKa: 8.3
Approximate pH range for colour change: 7.4-9.0
Colour of acid form: yellow
Colour of base form: purple

METANIL YELLOW

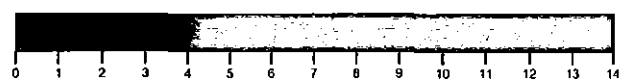


Approximate pKa: not reported
Approximate pH range for colour change: 1.2-2.4
Colour of acid form: red
Colour of base form: yellow

METHYL GREEN

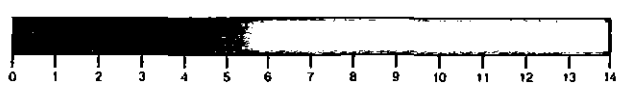
Approximate pKa: not reported
Approximate pH range for colour change: 0.2-1.8
Colour of acid form: yellow
Colour of base form: blue

METHYL ORANGE



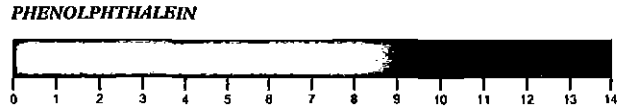
Approximate pKa: 3.8
Approximate pH range for colour change: 3.0-4.4
Colour of acid form: red
Colour of base form: yellow

METHYL RED



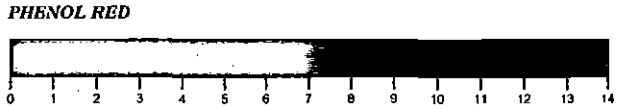
Approximate pKa: 5.0
Approximate pH range for colour change: 4.4-6.0
Colour of acid form: red
Colour of base form: yellow

PHENOLPHTHALEIN



Approximate pKa: 9.7
Approximate pH range for colour change: 8.3-10.0
Colour of acid form: clear
Colour of base form: red-violet

PHENOL RED



Approximate pKa: 7.4
Approximate pH range for colour change: 6.8-8.4
Colour of acid form: yellow
Colour of base form: red

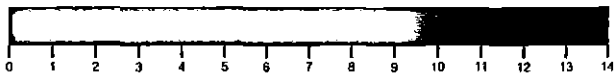
QUINALDINE RED

Approximate pKa: not reported
Approximate pH range for colour change: 1.0-2.2
Colour of acid form: clear
Colour of base form: red

RESAZURIN

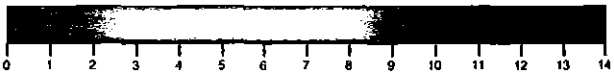
Approximate pKa: not reported
Approximate pH range for colour change: 3.8-6.4
Colour of acid form: orange
Colour of base form: violet

THYMOLPHTHALEIN



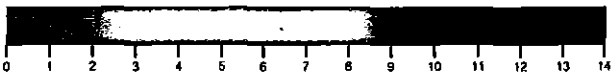
Approximate pKa: 9.9
Approximate pH range for colour change: 9.3-10.5
Colour of acid form: colourless
Colour of base form: blue

THYMOL BLUE (IN ACID SOLUTION)



Approximate pKa: 1.7
Approximate pH range for colour change: 1.2-2.8
Colour of acid form: red
Colour of base form: yellow

THYMOL BLUE (IN BASIC SOLUTION)



Approximate pKa: 8.9
Approximate pH range for colour change: 8.0-9.6
Colour of acid form: yellow
Colour of base form: blue

Supplementary Chapter VII

Traditional Herbal Medicines

This Supplementary Chapter provides information on Traditional Herbal Medicines.

A. Traditional Herbal Medicines

Introduction

This Supplementary Chapter provides information to help the users of the British Pharmacopoeia gain a greater understanding of the process behind the elaboration of monographs for traditional herbal medicines.

Traditional Herbal Medicinal Products (THMP) are classed as medicines under Part 7 of the Human Medicines Regulations 2012, as amended. The publication of monographs is intended to provide objective and publicly available standards of quality. It is emphasised that, although the monographs provide standards for quality, the British Pharmacopoeia Commission has not assessed the safety or efficacy of the herbal medicines.

British Pharmacopoeia monographs for traditional herbal medicines are identified for development in accordance with criteria referred to in Supplementary Chapter III B, in particular the degree of use of a traditional herbal medicinal product.

Some commercially available samples of herbal materials are processed herbal drugs. Where the herbal material is used in the processed form, only the processed form is readily available as an item of commerce in Europe. Where the processed herbal drug is used and where it is possible to obtain authenticated reference herbal samples for both the unprocessed and the processed herbal materials, two separate monographs have been elaborated. Processing methods may have the ability to alter the physical characteristics and/or the chemical constituents of a herbal drug. The two types of monographs are distinguished by means of the monograph titles. Monographs for the processed herbal drug include a 'Production statement' providing information on the method of processing.

The ultimate aim is to ensure that the quality of the monographs for the unprocessed and processed herbal drugs is of an equivalent standard to those of established monographs for herbal drugs.

The herbal samples used for the development of the monographs are authenticated independently. Specific limit tests may be prescribed to detect potential contaminants in processed herbal drugs. Other than the monograph titles the quality of the monographs for traditional herbal medicines are the same as established pharmacopoeial monographs for herbal drugs.

Monograph Titles

For traditional herbal medicinal ingredients, the monograph title is usually a combination of the binomial name together with a description of use (see the paragraph below).

A monograph carries the title of the herbal ingredient and any appropriate synonyms. Because of regional variations in names, spelling variations and the likelihood of existence of other established terms in the countries of origin, Anglicised versions of the traditional names, for example Pinyin names, Ayurvedic names and also Chinese and Ayurvedic symbols will not be included as monograph titles.

To distinguish between monographs for unprocessed and the processed herbal drug, the word 'Processed' is included in the relevant monograph title.

Control Methods

Where applicable, the control methods outlined below will be applied:

(1) macroscopical and microscopical descriptions and chemical/chromatographic tests for identification;

(2) tests for absence of any related species;

(3) microbial test to assure microbial quality;

(4) where appropriate, tests for inorganic impurities, pesticides, aflatoxins and heavy metals;

(5) where appropriate, non-specific purity tests, including extractive tests and sulfated ash;

(6) wherever possible, a method for assaying the active constituent(s) or suitable marker substance(s);

(7) when more than one species/subspecies of the same plant are included in the Definition, individual differences between the two are indicated where possible.

Macroscopical Description The macroscopical description includes those features that can be seen by the unaided eye or by the use of a hand lens.

Microscopical Description The microscopical description of the powdered herbal drug gives information on the diagnostic characters. Example micrographs are being introduced on the website of the British Pharmacopoeia (http://www.pharmacopoeia.com).

Chromatographic tests Diagrammatic representation of the TLC plate will be included in the monograph as an aid to identification of the various constituents.

Other tests In the tests for Acid-insoluble ash, Ash, Extractive soluble in ethanol, Loss on drying, Sulfated ash, Water, Water-soluble ash and Water-soluble extractive of herbal drugs, the calculations will be made with reference to the herbal drug that has not been specifically dried unless otherwise prescribed in the monograph. Samples used for the development of the monographs are free from moulds, insects, decay, animal matter and animal excreta. Unless otherwise prescribed the amount of foreign matter will not be more than 2% w/w. Microbial contamination is such that a traditional herbal medicinal product complies with the acceptance criteria for the stated route of administration as recommended in Appendix VII D and G.

Assay When determining the content of the active constituents or the suitable marker substances measurements are made with reference to the dried or anhydrous herbal drug.

B. Names of Herbal Drugs Used in Traditional Chinese Medicine

(Ph. Eur. general text 5.22)

This general chapter is published for information.

For transparency, this general chapter provides cross-references to the Chinese names in pinyin and in sinograms for herbal drugs used in traditional Chinese medicine for which a monograph is published in the Ph. Eur.

However, the titles in English, French and Latin are the only official names; the samples of herbal drugs must be labelled with at least one official title.

Monograph number	Latin title	English title	Pinyin	Sinogram
2827	Abelmoschi corolla	Abelmoschi corolla	*huangshukuihua*	黄蜀葵花
2432	Acanthopanacis gracilistyli cortex	Acanthopanax bark	*wujiapi*	五加皮
2999	Achyranthis bidentatae radix	Achyranthes bidentata root	*niuxi*	牛膝
2472	Akebiae caulis	Akebia stem	*mutong*	木通
2554	Amomi fructus	Amomum fruit	*sharen*	砂仁
2555	Amomi fructus rotundus	Round amomum fruit	*doukou*	豆蔻
2712	Andrographidis herba	Andrographis herb	*chuanxinlian*	穿心莲
2661	Anemarrhenae asphodeloides rhizoma	Anemarrhena asphodeloides rhizome	*zhimu*	知母
2556	Angelicae dahuricae radix	Angelica dahurica root	*baizhi*	白芷
2557	Angelicae pubescentis radix	Angelica pubescens root	*duhuo*	独活
2558	Angelicae sinensis radix	Angelica sinensis root	*danggui*	当归
2435	Astragali mongholici radix	Astragalus mongholicus root	*huangqi*	黄芪
2559	Atractylodis lanceae rhizoma	Atractylodes lancea rhizome	*cangzhu*	苍术
2560	Atractylodis macrocephalae rhizoma	Atractylodes rhizome, largehead	*baizhu*	白术
1797	Aucklandiae radix	Aucklandia root	*muxiang*	木香
2561	Belamcandae chinensis rhizoma	Belamcanda chinensis rhizome	*shegan*	射干
2384	Bistortae rhizoma	Bistort rhizome	*quanshen*	拳参
2562	Bupleuri radix	Bupleurum root	*chaihu*	柴胡
2386	Carthami flos	Safflower flower	*honghua*	红花
2713	Chaenomeles fructus	Chaenomeles fruit	*Mu Gua*	木瓜
2430	Citri reticulatae epicarpium et mesocarpium	Mandarin epicarp and mesocarp	*chenpi*	陈皮
2463	Clematidis armandii caulis	Clematis armandii stem	*chuanmutong*	川木通
2714	Codonopsidis radix	Codonopsis root	*dangshen*	党参
2454	Coicis semen	Coix seed	*yiyiren*	薏苡仁
2715	Coptidis rhizoma	Chinese goldthread rhizome	*huang lian*	黄连
2976	Corydalis rhizoma	Corydalis rhizome	*yan husuo*	延胡索
2998	Cyathulae radix	Cyathula root	*chuanniuxi*	川牛膝
2890	Dioscoreae nipponicae rhizoma	Dioscorea nipponica rhizome	*chuanshanlong*	穿山龙
2473	Dioscoreae oppositifoliae rhizoma	Dioscorea oppositifolia rhizome	*shanyao*	山药
2563	Drynariae rhizoma	Drynaria rhizome	*gusuibu*	骨碎补
2564	Ecliptae herba	Eclipta herb	*mohanlian*	墨旱莲
2451	Ephedrae herba	Ephedra herb	*ma huang*	麻黄
2412	Eucommiae cortex	Eucommia bark	*duzhong*	杜仲
2718	Evodiae fructus	Evodia fruit	*wuzhuyu*	吴茱萸
2720	Forsythiae fructus	Forsythia fruit	*lianqiao*	连翘
2452	Fraxini chinensis cortex	Fraxinus chinensis bark	*qinpi*	秦皮
3001	Ganoderma lucidum	Ganoderma	*lingzhi* (*reishi*)	灵芝 (赤芝)
2565	Gardeniae fructus	Cape jasmine fruit	*zhizi*	栀子
2721	Gastrodiae rhizoma	Gastrodia rhizome	*tianma*	天麻
2722	Houttuyniae herba	Houttuynia herb	*yuxingcao*	鱼腥草
2566	Isatidis radix	Isatis root	*banlangen*	板蓝根
2634	Ligustici chuanxiong rhizoma	Szechwan lovage rhizome	*chuanxiong*	川芎
2431	Ligustici radix et rhizoma	Ligusticum root and rhizome	*gaoben*	藁本
2612	Lycii fructus	Barbary wolfberry fruit	*gouqizi*	枸杞子
2723	Lycopi herba	Lycopus lucidus herb	*zelan*	泽兰
2742	Magnoliae biondii flos immaturus	Magnolia biondii flower bud	*xinyi*	辛夷
2567	Magnoliae officinalis cortex	Magnolia officinalis bark	*houpo*	厚朴
2568	Magnoliae officinalis flos	Magnolia officinalis flower	*houpohua*	厚朴花
2977	Morindae officinalis radix	Morinda root	*bajitian*	巴戟天
2474	Moutan cortex	Moutan bark	*mudanpi*	牡丹皮
2383	Notoginseng radix	Notoginseng root	*sanqi*	三七
3000	Ophiopogonis radix	Dwarf lilyturf tuber	*maidong*	麦冬
2424	Paeoniae radix alba	Peony root, white	*baishao*	白芍
2425	Paeoniae radix rubra	Peony root, red	*chishao*	赤芍
2727	Persicariae tinctoriae folium	Indigo plant leaf	*liaodaqingye*	蓼大青叶
2477	Piperis fructus	Pepper	*hujiao*	胡椒
2453	Piperis longi fructus	Long pepper	*bibo*	荜茇
2660	Platycodonis radix	Platycodon root	*jiegeng*	桔梗
2724	Polygoni cuspidati rhizoma et radix	Polygonum cuspidatum rhizome and root	*huzhang*	虎杖
2433	Polygoni multiflori radix	Fleeceflower root	*heshouwu*	何首乌
2726	Polygoni orientalis fructus	Polygonum orientale fruit	*shuihonghuazhi*	水红花子
2475	Poria	Poria	*fuling*	茯苓
2439	Prunellae spica	Common selfheal fruit-spike	*xiakucao*	夏枯草
2434	Puerariae lobatae radix	Kudzuvine root	*gegen* (*yege*)	葛根 (野葛)

Monograph number	Latin title	English title	Pinyin	Sinogram
2483	Puerariae thomsonii radix	Thomson kudzuvine root	*fenge*	粉葛
2569	Rehmanniae radix	Rehmannia root	*dihuang*	地黄
2663	Salviae miltiorrhizae radix et rhizoma	Salvia miltiorrhiza root and rhizome	*danshen*	丹参
2385	Sanguisorbae radix	Sanguisorba root	*diyu*	地榆
2428	Schisandrae chinensis fructus	Schisandra fruit	*wuweizi* (*bei wuweizi*)	五味子 (北五味子)
2438	Scutellariae baicalensis radix	Baical skullcap root	*huangqin*	黄芩
2450	Sinomenii caulis	Orientvine stem	*qingfengteng*	青风藤
2440	Sophorae flavescentis radix	Lightyellow sophora root	*kushen*	苦参
2639	Sophorae japonicae flos	Sophora flower	*huaihua*	槐花
2427	Sophorae japonicae flos immaturus	Sophora flower-bud	*huaimi*	槐米
2478	Stephaniae tetrandrae radix	Fourstamen stephania root	*fenfangji* (*hanfangji*)	粉防己 (汉防己)
2937	Typhae pollis	Typhae pollen	*puhuang*	蒲黄
2729	Uncariae rhynchophyllae ramulus cum uncis	Uncaria stem with hooks	*gou teng*	钩藤
2656	Zanthoxyli bungeani pericarpium	Zanthoxylum bungeanum pericarp	*huajiao*	花椒

C. Monographs on Herbal Drug Extracts (Information Chapter)

(Ph. Eur. general text 5.23)

Basis for elaboration of monographs on herbal drug extracts

European Pharmacopoeia monographs on herbal drug extracts are elaborated on the basis of extracts present in medicinal products that have been authorised and/or registered by the competent authorities of Parties to the Convention on the Elaboration of a European Pharmacopoeia. However, these monographs do not necessarily cover all extracts which may be available on the market.

European Pharmacopoeia monographs on herbal drug extracts are elaborated by groups of experts and working parties in collaboration with national pharmacopoeia authorities, the competent authorities for marketing authorisation, Official Medicines Control Laboratories (OMCLs) and the EDQM laboratory; they are also assisted by the producers of herbal drug extracts and/or the pharmaceutical manufacturers that use these extracts.

During the elaboration of an extract monograph, the group of experts works on the basis of a number of extracts from the specified herbal drug that are incorporated into authorised and/or registered medicinal products originating from different sources. These extracts may have been produced using different extraction solvents and/or extraction processes and may include different types and contents of excipients (added for technological purposes during production of the extract).

Where the results from the analysis of the extracts indicate that all of the extracts are in compliance with all of the quality parameters, the monograph is intended to apply to all types of production of that specific herbal extract (for example, *Devil's claw dry extract (1871)*, where differences in the extraction solvent used, as stated in the Production section of the monograph, and any differences between the extracts in terms of their production process have no significant effect on the quality parameters).

Where there is a definable difference in the quality parameters between the extracts due to one or more aspects of the production process, the monograph is presented as a family monograph in which there will be a qualitative or quantitative difference applicable to one or more analytical parameters (for example, *Boldo leaf dry extract (1816)*, where differences in the extraction solvents used, as stated in the Production section of the monograph, necessitates defining a lower minimum content of assayed constituents in the aqueous extract in comparison with the minimum content in the hydroalcoholic extract; all other quality parameters are identical).

Where there is a significant difference in the quality parameters between the extracts due to one or more aspects of the production process, more than one extract monograph is elaborated (for example, *Valerian dry aqueous extract (2400)* and *Valerian dry hydroalcoholic extract (1898)*, where differences in the extraction solvents used and the processing method, as stated in the Production section of the monographs, necessitates defining different minimum values for the assayed constituents and different chromatographic profiles for the aqueous and the hydroalcoholic extracts).

Types of extract

The general monograph *Herbal drug extracts (0765)* distinguishes different types of extracts. This classification is based on the principles applied by European competent authorities during the assessment of extracts in applications for marketing authorisation/registration of medicinal products. These principles are summarised in Table 5.23.-1.

This classification of extracts implies that, for each of these types of extract, distinct principles of production and of defining or adjusting the content of assayed constituents are required by the general monograph *Herbal drug extracts (0765)*.

Genuine (native) extract The concept of the genuine (native) drug extract ratio ($DER_{genuine}$) (see the Glossary in the monograph *Herbal drug extracts (0765)*) was originally devised for application to dry extracts where, after extraction of the herbal drug, all solvent is removed leaving only the extracted dry matter from the herbal drug, that is, the genuine (native) extract. However, this extracted dry matter often requires additives (inert excipients as processing aids) to produce a technologically suitable extract. Such extracts made by different manufacturers from a given herbal drug may have been produced using different solvents and processing methods and contain different amounts of excipients relative to the quantity of extracted dry matter. In order to permit comparison of such extracts, the declaration of the drug extract ratio (*DER*) on the basis of the genuine (native) extract was introduced. Thus, for those dry extracts which can be produced without excipients, the DER_{total} and the $DER_{genuine}$ are identical, but where excipients are required, the DER_{total} and the $DER_{genuine}$ are different.

Table 5.23.-1. – *Classification and principles of production of extracts*

Information available during assessment as regards pharmacological/therapeutic relevance of constituents	Extract type	Extract concept		Extract adjustment
		Quantitative parameters		
		Constituent to be analysed	Quantity of genuine (native) extract that is included in finished products	
Constituents with known therapeutic activity	Standardised	Constituents with known therapeutic activity *Constant*	*Variable*	1) By addition of inert excipients (dry extracts) or solvents (liquid extraction preparations or soft extracts) 2) By blending batches
Constituents which are generally accepted to contribute to the therapeutic activity	Quantified	Active marker *Range*	*Constant*	By blending batches
Constituents chosen solely for analytical purposes irrespective of any pharmacological or therapeutic activity which they may be reported to possess	Other	Analytical marker *Variable*	*Constant*	None

It was then thought necessary to apply this concept to soft extracts and liquid extraction preparations where solvent and, in some cases, other substances are present as an integral part of the extract. For these extracts, the concept of basing the $DER_{genuine}$ on extracted dry matter was abandoned and the extract in its entirety (including solvents, processing aids, etc.) is considered to be the genuine (native) extract. Therefore, for these extracts, the DER_{total} and the $DER_{genuine}$ are identical. For the declaration of the active substance in the finished product, only the $DER_{genuine}$ is to be used.

Constituents for assay

For the purposes of quality control, monographs of the European Pharmacopoeia generally include an assay. The choice of the constituent(s) to be assayed is linked, wherever possible, to the regulatory process and is based upon the following criteria:

— where constituents with known therapeutic activity are present, these are selected for assay.

Constituents with known therapeutic activity are chemically defined substances or groups of substances which are generally accepted to contribute substantially to the therapeutic activity of a herbal drug, a herbal drug preparation or a herbal medicinal product.

— where constituents with known therapeutic activity are absent, marker constituents are selected for assay.

Active markers are constituents or groups of constituents which are generally accepted to contribute to the therapeutic activity of an extract.

Analytical markers are constituents or groups of constituents that serve solely for analytical purposes, irrespective of any pharmacological or therapeutic activity which they may be reported to possess.

Use of analytical markers in 'other' extracts

The assay method described in an individual monograph:

— is usually derived from the method used to assay the corresponding herbal drug;
— is considered appropriate to determine the content of the chosen analytical marker;
— serves as a general analytical platform for determining the content of the marker in the individual extracts covered by the monograph for the purpose of quality control. The method may also be suitable for stability studies;
— may also be suitable as a basis for establishing assay methods to quantify the content of an extract in a finished medicinal product.

The minimum content of the analytical marker when using the assay method:

— is established by assaying extracts used in authorised and registered medicinal products;
— is given based on the final extract (genuine (native) extract with, where present, excipients);
— and thus:
  — represents the minimum value found in the extracts used for establishing the monograph after confirmation or modification following comments received from users, producers or national authorities during the public enquiry;
  — is related to the minimum value as stated in the corresponding herbal drug monograph;
  — reflects the range of yields of that particular marker from the extraction process as well as the stability of that marker during manufacturing;
  — is dependent on the amount of excipients added for technological reasons.

Since the monograph may encompass a broad range of extracts, the minimum value given for the analytical marker is not regarded as a stand-alone quality criterion (as compared to other minimum values given in the Pharmacopoeia). However, it gives an indication of the minimum values that can be expected when producing an extract from a herbal drug compliant with its monograph.

Based on the information given above, manufacturers may be requested by competent authorities to complement this information with a minimum value for their own extract depending on their individual manufacturing process and excipients added.

NOTE: information on the characteristics of the extracts (for example, strength of extraction solvent, percentage of genuine extract, etc.) analysed during the elaboration of an individual extract monograph will be made available to users of the European Pharmacopoeia in the Knowledge database on the EDQM website.

D. DNA Barcoding as a tool for Botanical Identification of Herbal Drugs

This Supplementary Chapter concerns the use of DNA barcoding as a tool for botanical identification of herbal drugs. For the purposes of identification, DNA barcoding has been widely accepted as sufficiently robust and is considered an appropriate method for molecular identification of herbal materials.

INTRODUCTION

In generating the reference barcode sequences published for a herbal drug, several barcode regions are examined including the nuclear Internal Transcribed Spacer (*nrITS*) and several plastid regions; *trnH-psbA, rbcL, trnL-F* and *matK*. The most informative region is identified for each herbal drug, based on the specificity of the DNA sequence to the named species. The species specific sequence for that region is published, highlighting the bases that are essential for identification. Further barcode regions will be examined when no species specific sequences occur in the regions named above.

When a DNA-based identification technique is specified in a monograph for a herbal drug, the identified barcode region and its species specific sequence (reference sequence) will be published as part of the monograph. Where the barcode analysis for a herbal drug has been completed by the BP, but the DNA-based identification technique is not specified as an identification method in the monograph, the barcode region and reference sequence will form part of this Supplementary Chapter.

The usual method of obtaining a barcode sequence from plant material is by DNA extraction, Polymerase Chain Reaction (PCR) and Sanger sequencing. Appendix XI V 'Deoxyribonucleic Acid (DNA) Based Identification Techniques for Herbal Drugs' provides further details. This Appendix encompasses the theory of DNA-based techniques, the infrastructure required, controls and general methods. When a reference sequence is published in a herbal drug monograph or in this Supplementary Chapter the chosen barcode region and any deviations from the published Appendix XI V method for that barcode region will be given either in the herbal drug monograph or in this Supplementary Chapter, as applicable.

Sanger Sequencing: Application and Limitations

Sanger sequencing is the most widely used and easily accessible form of DNA sequencing. However, there are limitations to this technique when applied to herbal drugs, including the inability to detect adulterants, lack of information on purity, potential problems of application to degraded DNA samples, and higher cost, time and technical skill requirements when compared with other DNA-based techniques. To address these limitations, the feasibility of the use of alternative techniques is being investigated and will be applied when appropriate. For example, where adulteration is known to be an issue, consideration will be given to designing a technique that identifies and quantifies the target species and the adulterant species simultaneously. This Supplementary Chapter will be updated to reflect other DNA-based methods as and when they are applied within the BP.

REFERENCE MATERIAL – BRITISH PHARMACOPOEIA NUCLEIC ACID REFERENCE MATERIAL (BPNARM)

To confirm the suitability of the DNA extraction, the PCR chemistry and working practices, appropriate British Pharmacopoeia Nucleic Acid Reference Materials (BPNARM) will be available to end users. Reference electrophoresis results (Figure 1) will be produced in the leaflets for BPNARMs showing the pattern of banding that satisfies the criteria for acceptance.

TABLE 1
REFERENCE ELECTROPHORESIS RESULTS

Lane 1	Amplification product from herbal drug
Lane 2	Amplification product showing both the herbal drug and the BPNARM band. This is the DNA extraction control
Lane 3	Amplification product of the BPNARM alone, the PCR positive control
Lane 4	Negative control with no amplification product visible

TABLE 2
CRITERIA FOR ACCEPTANCE

Lane 1	Visible band from the plant DNA
Lane 2	245 bp band from the BPNARM. The band from the plant DNA may or may not be present
Lane 3	245 bp band from the BPNARM
Lane 4	No band

The suitability of the DNA extraction process used is shown by the results in Lanes 1 to 3 by the banding pattern present. More specifically the BPNARM band is shown in Lanes 2 and 3. As this material is provided as a known DNA sample that amplifies with the method given, an absence of the 245 bp band in both Lanes 2 and 3 shows that the process has not been completed satisfactorily. It is possible for compounds present in the herbal drug to co-purify with the DNA sample, inhibiting the PCR so that no band is formed. Should this occur the subsequent banding pattern would show no bands in Lane 2, due to inhibition, but a 245 bp band in Lane 3, because no plant material is present and therefore no inhibitory compounds. Without the use of the BPNARM it is difficult to discern whether the DNA extraction or the presence of inhibitory compounds has caused the failure of the PCR. Another possibility is that the DNA in the herbal drug may be too degraded to amplify; this would result in the BPNARM bands being formed, but no bands from the plant DNA (Lanes 1 and 2 in Figure 1). The suitability of the PCR chemistry and instrumentation used is verified by the production of the 245 bp BPNARM band in Lane 3. The reaction that produces the band in Lane 3 is the PCR positive control. If a band is not produced from this reaction then there is a problem with either: the components used to make up the reaction, the thermal cycler or the program entered into it, or a user error in the preparation of the reaction mixture.

The suitability of the working practices used to produce the PCRs and the agarose gel electrophoresis system by which to view the amplification products is verified by the presence of a band from the positive control reaction and also by the absence of any other unexplained banding. Lane 4 on Figure 1 is the PCR 'negative control' for which the acceptance criterion is the absence of a band. Should a band be formed in Lane 4, this is likely to be due to contamination of the PCR with extraneous DNA. Similarly, if an unexplained band is found in any of the lanes, this may show contamination of the PCR and/or the DNA extraction, or the adulteration of the herbal drug from which the DNA was extracted.

For the *Ocimum tenuiflorum* barcoding method specified in Appendix XI V a reference material *trnH-psbA* BPNARM has been developed and is listed in the BP Reference Standards

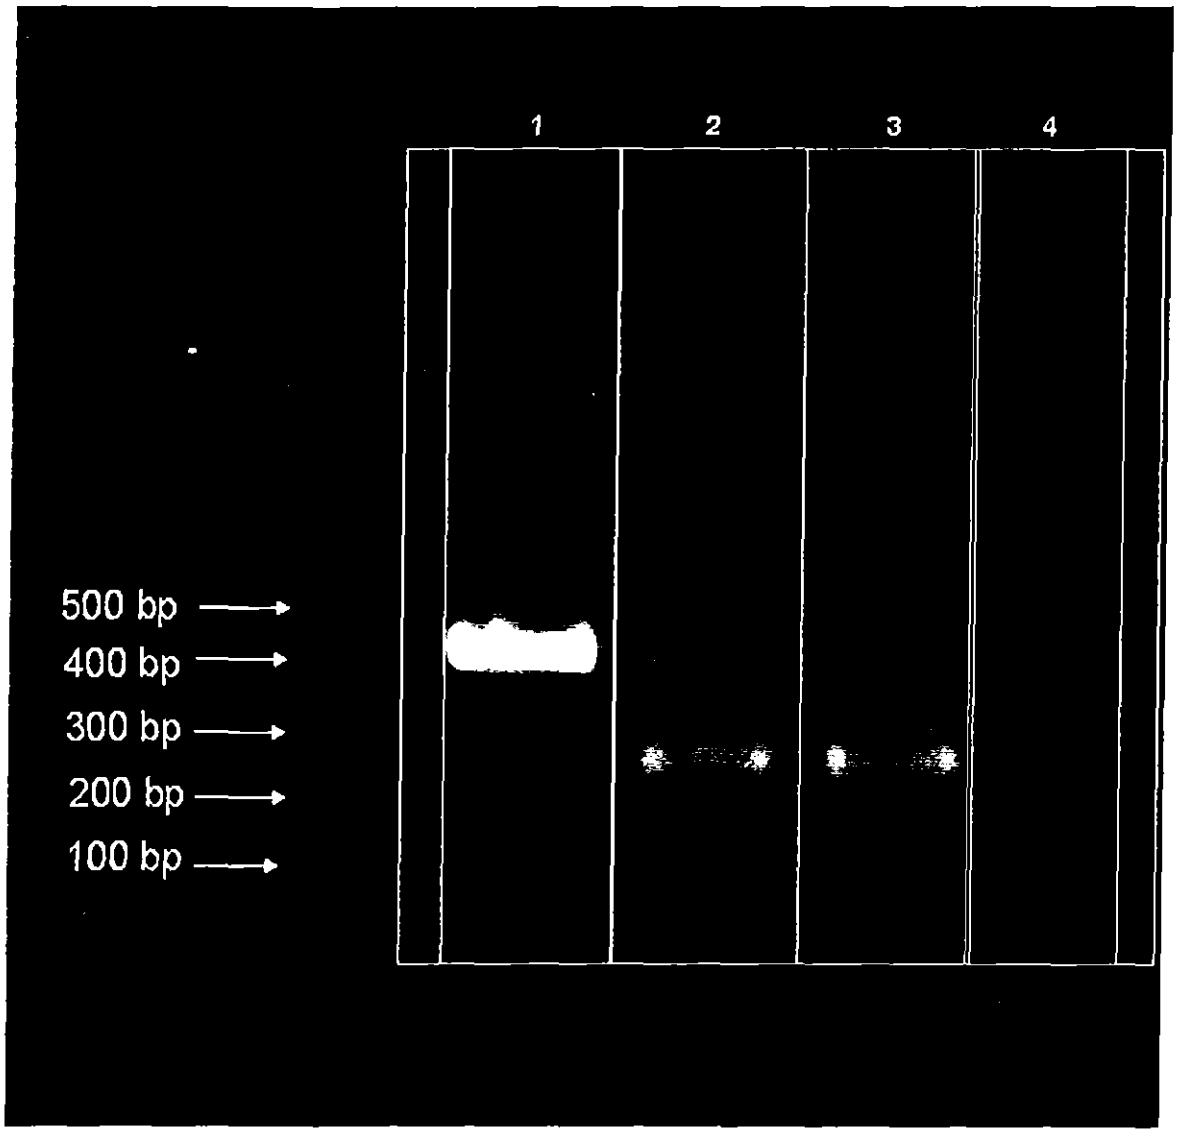


Figure 1 - *Reference electrophoresis results*

Catalogue. This is available through the BP Website (http://www.pharmacopoeia.com). A BPNARM is not tied to one species, but to the chosen DNA barcode region. Therefore, the *trnH-psbA* BPNARM will be applicable to all DNA-based identification techniques based on sequencing the *trnH-psbA* plastid region.

REFERENCE SEQUENCES

When reference DNA sequences are provided, either as one of the identification methods in a monograph or in this Supplementary Chapter, they are published with the key bases for identification indicated by lower case text. In some reference sequences the degenerate DNA code is used, this gives information about the permitted bases at any one position when variation is known to occur. For example, in sequences where variation is seen between a Cytosine (C) and a Thymine (T) at a base position, the degenerate code Y is shown. This means that either a Cytosine (C) or a Thymine (T) would be permitted at the base position, but rules out a Guanine (G) or an Adenine (A) base. The full degenerate code is shown in Table 3.

TABLE 3
DEGENERATE DNA CODE

Code	Meaning
K	G or T
M	A or C
R	A or G
Y	C or T
S	C or G
W	A or T
B	C or G or T
V	A or C or G
H	A or C or T
D	A or G or T

The matching of DNA sequences produced from samples against a published BP Reference Sequence can be achieved by the use of DNA sequence alignment software. Many applications are available for this including internet based, free access portals. Query sequences should be aligned with the relevant BP Reference Sequence and the results are given in both percentage similarity of sequences and full images of the entire alignment. It is possible to upload query sequences from multiple samples to be aligned with a BP Reference Sequence simultaneously. Careful attention must be paid to

the key bases for identification as these must match exactly and be checked manually.

The BP Reference Sequences are provided along with any additional information considered helpful to the analyst in the analysis of samples using an Appendix XI V method. This will include adaptations to optimise DNA extraction and purification methods, and details of sequencing primers. Sequencing is often carried out using the PCR amplification primers, but it can be useful to use different primers at this stage depending on the DNA sequence.

GLOSSARY
TABLE 4

Term	Definition
Amplicon	The DNA product of a PCR.
Amplification	The copying of DNA during a PCR.
Base call	The identification of a DNA base by sequencing software.
Base pair (bp)	The complementary pairing of two nucleotides, A&T or G&C, which forms the unit of measurement for the length of a DNA molecule.
BPNARM	British Pharmacopoeia Nucleic Acid Reference Material.
Consensus sequence	The product of the combining of several individual DNA sequencing reads, providing a consensus of the correct sequence.
Contig	A set of overlapping DNA sequencing reads from one sample which can be used to produce a consensus sequence.
Deoxynucleotide (dNTP)	The monomer or individual unit of DNA; Adenine (A), Cytosine (C), Guanine (G) and Thymine (T).
di-deoxynucleotide (ddNTP)	A modified form of the DNA monomer without an -OH group present on the 3′ carbon of the deoxyribose sugar which is required to bind a subsequent nucleotide.
DNA	Deoxyribonucleic Acid, a double stranded, helical molecule.
DNA ladder	Mixture of DNA molecules of known base pair length. These provide a measure of how far a DNA molecule travels during gel electrophoresis.
Master mix	A mixture containing the common components for several PCRs, this is made in a large batch or master mix which is then divided between individual reactions. Master mixes contain enough reagents for the required number of tests, typically plus one to allow for pipetting errors.
Mix by pipetting	Drawing up and expelling a substance up to ten times using an automatic pipette, with the aim of mixing the solutions.
Water MB	Deionised, filtered and autoclaved water.
Negative control	A reaction which comprises all but one essential component, thereby proving the necessity of the absent substance.
PCR	Polymerase Chain Reaction - an enzyme driven reaction where DNA molecules are replicated.
Phred score	The likelihood that a base call in a DNA sequence is incorrect, a score of 20 has a 1 in 100 probability of being an incorrect call, 30 is 1 in 1000 etc.
Positive control	A reaction comprising all common PCR components and a known DNA sample, thereby proving the suitability of all reagents.
Primer (oligonucleotide)	A short single stranded DNA molecule which binds to the DNA to be amplified in a PCR. This enables the enzyme to commence replication, and therefore the binding positions define the start and finish point of the PCR.
Probe hybridisation	The complementary binding of an oligonucleotide to a target DNA molecule causing a measurable response.
Sanger sequencing	The method by which a DNA sequence is resolved, developed by Frederick Sanger and colleagues.
Sequencing	Identifying the order of the nucleotide sequence of DNA.
Thermal cycler	The machine that performs the cycling of temperatures required for a PCR.

E. Methods of Pretreatment for Preparing Traditional Chinese Drugs: General Information

(Ph. Eur. general text 5.18)

The following chapter on methods of pretreatment (炮制 paozhi) for preparing traditional Chinese drugs is published for information only.

On the European market, traditional Chinese drugs (herbal, mineral or animal drugs) exist in both pretreated and crude forms. The different forms may be covered by a single monograph or, preferably, by separate monographs.

Regarding herbals, depending on the pretreatment methods used, the products of pretreatment can be herbal drugs or herbal drug preparations. The structure of the method descriptions below is not related to any classification of the resulting products as herbal drugs or herbal drugs preparations. The competent authorities may require a detailed description of the method of pretreatment, including information on the quality of the excipients used.

Terminology: the original Chinese technical terms describing the methods of pretreatment are used, with their English translation. Sinograms and pinyin names (the latter expressing the phonetic transcription) are kept in the text as a reference to guarantee the correct translation of the original terms in case of translation to languages other than French and English. The technical term 'processing', which is widely used in international literature on traditional Chinese medicine (TCM), cannot be used in this context, as it is misleading with respect to the definitions given in the European laws.

1 INTRODUCTION

In contrast to other herbal drugs, drugs used by practitioners of traditional Chinese medicine are rarely in the genuine crude state but in a pretreated form instead.

The pretreatment procedures are different from the common methods already described in the general monograph *Herbal drug preparations (1434)*.

This chapter provides a brief description of the traditionally used pretreatment procedures, as defined in the Chinese Pharmacopoeia.

The major formulation in traditional Chinese therapy is the decoction.

Due to the often very voluminous drug material but also due to other reasons stated below, crude drugs are in many cases not suitable as a raw material for decoctions, and are pretreated before use.

Pretreatments may be used to:

- achieve drugs of consistent quality and size for greater, reproducible effect and better storability (cutting or fragmenting mainly under wet conditions followed by drying procedures);
- reduce toxic effects or undesirable effects of toxic crude drugs;
- modify the effect of the drug;
- increase the effect of the drug;
- modify the extractability of the drug material;
- increase stability and remove unpleasant taste;
- prepare new and modified drug material by fermentation.

Only cleaned drugs are to be used as raw material for pretreatment.

2 CLEANING AND REFINING PROCEDURES: (净制 *JINGZHI*)

Cleaning and refining procedures include sorting (挑选 *tiaoxuan*), sifting (筛选 *shaixuan*), sorting by wind (风选 *fengxuan*), sorting by rinsing with water (水选 *shuixuan*), cutting (剪 *jian*), scraping (刮 *gua*), paring (削 *xue*), rejecting foreign matter (剔除 *tichu*), fermenting (酶法 *meifa*), peeling (剥离 *boli*), pressing (挤压 *jiya*), blanching and rubbing (燀 *chan*), brushing (刷 *shua*), scrubbing (擦 *ca*), singeing with fire (火燎 *huoliao*), throwing in boiling water (烫 *tang*), crushing (撞 *zhuang*), and deburring (碾串 *zhanchuan*).

3 CUTTING (切制 *QIEZHI*)

Unless cut in fresh or dry form, crude traditional Chinese drugs are moistened to soften them prior to cutting. Moistening is preferable to soaking in water which should be avoided in order to prevent the loss or reduction of active principles. The crude drugs are treated according to their size, diameter and hardness, noting the temperature, quantity of water and duration of treatment. The drugs are dried directly after cutting. Dried crude traditional Chinese drugs may be cut into slices, sections, pieces, slivers and other fragments. Their size and thickness are generally as follows.

Slices Less than 0.5 mm in thickness for very thin slices; 1-2 mm in thickness for thin slices; 2-4 mm in thickness for thick slices.

Sections 10-15 mm in length.

Pieces Cubes of 8-12 mm.

Slivers 2-3 mm in width for narrow slivers; 5-10 mm in width for broad slivers.

Crude traditional Chinese drugs other than those treated by cutting are usually pounded or crushed.

4. TREATMENT BY HEATING

4-1 Dry-frying

(炒 *chao*). This method can be divided into simple dry-frying (清炒 *qingchao*, 单炒 *danchao*) and dry-frying with excipients. When dry-frying, stir constantly under homogeneous heating, controlling the temperature, the duration and the condition of individual drugs.

4-1-1 Simple dry-frying

(清炒 *qingchao*, 单炒 *danchao*). Clean crude drugs are placed in a suitable container and dry-fried under gentle heat, taken out and allowed to cool. Crude drugs that should be dry-fried to charring are treated at a relatively high temperature until the surface of the drug turns brown and the fractures become dark. Crude drugs that are inflammable on dry-frying to char may be sprayed with a small amount of water, then dry-fried to dryness or dried in the sun.

4-1-2 Dry-frying with bran

(麸炒 *fuchao*). Bran is put in a suitable, hot container and heated until smoke appears; the clean crude drugs are added and stirred quickly until their surface turns yellow or dark, then taken out. The bran is sifted out and the drugs allowed to cool.

10-15 parts of bran are usually used for 100 parts of clean crude drugs.

4-1-3 Dry-frying with sand

(砂炒 *shachao*). Clean sand is put in a suitable container and heated at high temperature until the sand can move smoothly. The clean crude drugs are added and stirred until the drugs become crisp or reach a specified condition, then taken out. The sand is sifted out and the drugs allowed to cool. The quantity of sand usually used is just enough to cover the crude drugs. Drugs that require tempering with

vinegar are dipped into vinegar while hot until they become crisp.

4-1-4 Dry-frying with powdered clam-shell
Meretricis/Cyclinae concha
(蛤粉炒 *gefenchao*). Powdered and sifted clam-shell is put in a suitable container and heated at medium temperature until the powder can move smoothly. The clean crude drugs are added and dry-fried until the drugs become crisp, their surface becomes yellow or they reach a specified condition, then taken out immediately. The powdered clam-shell is sifted out and the drugs allowed to cool.

30-50 parts of powdered clam-shell are usually used for 100 parts of clean crude drugs.

4-1-5 Dry-frying with talc
(滑石粉炒 *huashifenchao*). Talc is put in a suitable container and heated at medium temperature until the powder can move smoothly. The clean crude drugs are added and dry-fried until the drugs become crisp, their surface becomes yellow or they reach a specified condition, then taken out immediately. The talc is sifted out and the drugs allowed to cool.

40-50 parts of talc are usually used for 100 parts of clean crude drugs.

4-2 Frying
(炙 *zhi*). The clean crude drugs are mixed with a liquid excipient until they are moistened, then heated to a specified condition.

4-2-1 Frying with wine
(酒炙 *jiuzhi*). The clean crude drugs are mixed with wine and allowed to stand until they are completely moistened, then placed in a suitable container and gently heated to a specified condition, taken out and allowed to cool.

Yellow rice wine is usually used. 10-20 parts of wine are used for 100 parts of clean crude drugs.

4-2-2 Frying with vinegar
(醋炙 *cuzhi*). The clean crude drugs are mixed with vinegar and allowed to stand until they are completely moistened, then placed in a suitable container and gently heated to a specified condition, taken out and allowed to cool.

Rice vinegar is usually used. 20 parts of vinegar are used for 100 parts of clean crude drugs.

4-2-3 Frying with salt-water
(盐炙 *yanzhi*). The sodium chloride is dissolved in an appropriate quantity of water and the solution is filtered. The clean crude drugs are mixed with salt-water and allowed to stand until they are completely moistened, then placed in a suitable container and gently heated to a specified condition, taken out and allowed to cool.

2 parts of sodium chloride are usually used for 100 parts of clean crude drugs.

4-2-4 Frying with ginger juice
(姜炙 *jiangzhi*). The fresh ginger is crushed to a paste, water is added and juice is obtained by squeezing. The operation is repeated once and the juices combined. The yield of ginger juice to fresh ginger is 1:1 (volume/mass). The clean crude drugs are mixed well with the ginger juice, then gently heated until the ginger juice is absorbed completely, or to a specified condition, taken out and allowed to cool.

10 parts of fresh ginger are usually used for 100 parts of clean crude drugs.

4-2-5 Frying with honey
(蜜炙 *mizhi*). Refined honey is diluted in an appropriate quantity of boiling water. The clean crude drugs are added, mixed and allowed to stand until they are completely moistened, then placed in a suitable container and gently heated to a specified condition, taken out and allowed to cool.

25 parts of refined honey are usually used for 100 parts of clean crude drugs.

4-2-6 Frying with fat
(油炙 *youzhi*). Fat is heated until it melts, the unmelted residue is removed and the clean crude drugs added, mixed well and gently heated until the fat is completely absorbed and their surface is glossy. The drugs are spread out and allowed to cool.

4-3 Carbonising
(制炭 *zhitan*)

4-3-1 Carbonising by dry-frying
(炒炭 *chaotan*). The clean crude drugs are placed in a hot suitable container and dry-fried at a high temperature until the surface of the drugs turns brownish-black and the inner parts turn dark brown, or to a specified condition, sprayed with a small quantity of water, taken out and allowed to cool.

4-3-2 Carbonising by calcining
(煅炭 *duantan*). The clean crude drugs are placed in a calcining pot, tightly closed, heated to a specified condition, allowed to cool and taken out.

4-4 Calcining
(煅 *duan*). The clean crude drugs are calcined until they become crisp and easily crushed.

4-4-1 Calcining openly
(明煅 *mingduan*). The clean crude drugs are fragmented to small pieces, placed in a suitable container and calcined until the drugs become crisp, brittle or red hot. They are taken out, cooled and crushed to a powder.

Inorganic salts containing water of crystallisation are not calcined to red hot, but the water of crystallisation is completely evaporated or the drugs are calcined to honeycomb-like, solid masses.

4-4-2 Calcining and quenching
(煅淬 *duancui*). The clean crude drugs are calcined to red hot and dipped quickly into a specified liquid until they become crisp (the operation is repeated if necessary), taken out, dried, and crushed to a powder.

4-5 Steaming
(蒸 *zheng*). Water or liquid excipient is added to the clean crude drugs, previously classified according to size; they are mixed well and allowed to stand until the drug is moistened. The mixture is placed in a suitable container and steamed to a specified condition. The drugs are taken out, cooled, mixed with the steaming liquid, partly dried in air, cut into slices or sections and allowed to dry.

20-30 parts of water or liquid excipient are usually used for 100 parts of clean crude drugs.

4-6 Boiling
(煮 *zhu*). The clean crude drugs, classified according to size, are boiled with water or liquid excipient until no white colour is observed in the centre of the drugs, taken out, partly dried in air, cut into slices and allowed to dry.

20-30 parts of water or liquid excipient are usually used for 100 parts of clean crude drugs.

4-7 Stewing
(炖 *dun*). Water or liquid excipient is added to the clean crude drugs. They are placed in a suitable container, tightly closed, stewed thoroughly on a water bath or by steaming

until the liquid is entirely absorbed, allowed to cool, taken out, partly dried in air, cut into slices and allowed to dry.

20-30 parts of water or liquid excipient are usually used for 100 parts of clean crude drugs.

4-8 Roasting

(煨 *wei*). The clean crude drugs are wrapped with wet flour or wet paper, or placed regularly between layers of oil-absorbent paper, and heated. Alternatively, the clean crude drug is put together with bran in a suitable container, gently heated to a specified extent and allowed to cool.

50 parts of bran are usually used for 100 parts of clean crude drugs.

5. OTHER TREATMENTS

5-1 Blanching in boiling water

(燀 *chan*). The clean crude drugs are put in boiling water, stirred for a short time and taken out. Some seeds are blanched until the wrinkled testae become extended and smooth and can be removed easily; they are then taken out and soaked in cold water to remove the testae, and then dried in the sun.

5-2 Defatted powder

(制霜 *zhishuang*). The clean crude drugs are usually crushed to a paste, heated gently and pressed to remove some of the oil, to make a fairly dispersible powder.

5-3 Aqueous trituration and flotation

(水飞 *shuifei*). Water is added to the clean crude drugs and they are pulverised to fine particles. More water is added and, after stirring, the supernatant liquid is decanted. The operation is repeated on the sediment several times, the final sediment is removed and the suspensions of fine particles are combined and allowed to settle. Settled particles are separated, dried and reduced to a fine powder.

5-4 Sprouting

(发芽 *faya*). The clean crude drugs are soaked in an appropriate quantity of water, taken out and allowed to sprout to a specified extent at a suitable humidity and temperature, then dried in the sun or at a low temperature.

5-5 Fermenting

(发酵 *faxiao*). The clean crude drugs are mixed with specific excipients, given a specific shape and placed at a suitable humidity and temperature to let micro-organisms grow until the enzyme content has reached a specified range. The drugs are then dried in the sun or at a low temperature.

Supplementary Chapter VIII

Materials for use in the Manufacture of Homoeopathic Preparations

This Supplementary Chapter provides information on Materials for use in the Manufacture of Homoeopathic Preparations.

Introduction

This Supplementary Chapter provides information to help the users of the British Pharmacopoeia gain a greater understanding of the process for elaborating monographs for materials for use in the manufacture of homoeopathic preparations.

Homoeopathic Medicinal Products are classed as medicines under Part 8 of the Human Medicines Regulations 2012, as amended. Homoeopathic Medicinal Products are defined as '*any medicinal product prepared from substances called homeopathic stocks in accordance with a manufacturing procedure described by the European Pharmacopoeia or, in the absence thereof, by the pharmacopoeias currently used officially in the Member States. A homeopathic medicinal product may contain a number of principles.*'. As stated in the British Pharmacopoeia Supplementary Chapter III B concerning the circumstances for selecting materials for monograph development, the British Pharmacopoeia Commission's policy is to support relevant statutory instruments; this in particular relates to parts 6 and 8 of the Human Medicines Regulations 2012, as amended.

The publication of British Pharmacopoeia monographs for materials for use in the manufacture of homoeopathic preparations is intended to provide official, objective and publicly available standards of quality. It is emphasised that, although the monographs provide standards for quality, it is not the role of the British Pharmacopoeia Commission to assess the safety or efficacy of these materials.

To date, preparation of monographs for materials for use in the manufacture of homoeopathic preparations has been based on monographs present in the British Homoeopathic Pharmacopoeia and have been prioritised in accordance with the availability of these materials within the United Kingdom.

The ultimate aim is to ensure that the quality of the monographs for the herbal materials and chemicals for homoeopathic use are of an equivalent standard to those of established monographs for herbal drugs and chemicals.

Authenticated herbal samples should be used for the development of monographs for materials for use in the manufacture of homoeopathic preparations. When a plant species that is not part of the definition in the monograph is known to be a substituent or adulterant, an absence or limit test is included in the monograph where possible.

Monograph Titles

For materials for use in the manufacture of homoeopathic preparations, the title, including any subsidiary titles, includes '... for Homoeopathic Preparations'. The main title of a monograph for a chemical is the English name; the Latin name, where appropriate, is given as the subsidiary title.

Control Methods

In cases where the bulk starting material and any excipients for dilution or trituration are covered by a BP or Ph Eur monograph, the material and/or excipient must comply with the relevant pharmacopoeial monograph. If the material is not covered by an existing BP or Ph Eur monograph, tests to check the quality of the starting material are included in the specific monograph for homoeopathic materials.

Characteristics References to odour are only included where this is highly characteristic. References to taste are not included.

Identification: (a) Herbal drugs Reliance for identification of herbal homoeopathic materials is primarily placed on the macroscopical description. In addition, a microscopical description and thin-layer chromatographic test may be included to strengthen the identification.

The macroscopical description includes those features that can be seen by the unaided eye or by the use of a hand lens.

The microscopical description of the powdered herbal drug gives information on the diagnostic characters.

(b) Chemicals Tests such as specific colour reactions are included unless the raw material is already controlled within the British Pharmacopoeia.

Tests The following tests are applied, where applicable, in addition to the tests or requirements given in the monographs for Homoeopathic Preparations, Herbal Drugs for Homoeopathic Preparations and Mother Tinctures for Homoeopathic Preparations:

(1) tests for absence of any related species;

(2) microbial tests to assure microbial quality;

(3) where appropriate, tests for inorganic impurities, pesticides, aflatoxins and heavy metals;

(4) non-specific purity tests, including extractive tests and sulfated ash.

Monographs for mother tinctures The control of the herbal drug is followed by a separate section entitled 'Mother Tincture' that states the method of production followed by the relevant control tests.

Monographs for chemical stocks The format and layout is similar to that for mother tinctures above, whereby the control of the chemical is followed by a separate heading section entitled 'Production of Stock' that states the method of production followed by the relevant control tests.

Production A cross-reference is made to the method of manufacture given in the monograph entitled Methods of Preparation of Homoeopathic Stocks and Potentisation. If the method is not included, a general statement relating to a suitable method is included in the specific monograph. When a British Pharmacopoeia or European Pharmacopoeia monograph exists for a vehicle or excipient, that vehicle or excipient complies with the monograph.

Tests Identification tests are included for the mother tincture or chemical stocks; vehicles and/or excipients used are also identified. No testing is given for subsequent dilutions or triturations owing to the difficulty in applying analytical methodology to high dilutions. In the case of mother tinctures thin-layer chromatography is usually specified for the identification.

Assay When an assay is given for the bulk material, it is also applied to the relevant mother tincture or chemical stock. Where necessary, the method includes a means of overcoming interference from excipients.

Supplementary Chapter IX

Similar Biological Medicinal Products

This Supplementary Chapter provides a statement on the Pharmacopoeial position in relation to similar biological medicinal products and aspects for consideration concerning preparation of relevant monographs.

Pharmacopoeial position

Introduction

The term 'similar biological medicinal product' is used for a biological product that has been developed to be similar to an authorised biological medicinal product ('reference' product). The term 'biosimilar' has been used interchangeably with 'similar biological medicinal product'. For Great Britain, reference for more information should be made to the applicable EU Guidance on similar biological medicinal products specifically referred to in the Human Medicines Regulations 2012, as amended. For Northern Ireland, reference for more information should be made to the most recent Committee for Medicinal Products for Human Use (CHMP) Guidelines on similar biological medicinal products and other related position papers published by the European Medicines Agency (EMA).

Consistent with the established principles set out in the Human Medicines Regulations 2012, as amended, biological medicinal products, in view of their complexity, differ from conventional medicinal products based on chemically synthesised substances. Similar biological products cannot be regarded as comparable to generic medicinal products. They are likely to be derived from starting materials or manufacturing processes different from those used for the authorised reference biological product. Consequently, even though a 'similar biological medicinal product' is developed to be as close as possible in structure and activity to the reference product, there may be differences in the detailed structure of the active ingredient from that of the 'reference' product. Any difference may result in altered properties that impact on the immunogenicity and clinical performance. Such differences have led to recommendations that similar biological medicinal products should be prescribed by brand only. Additional requirements for proof of safety and efficacy have usually been required when compared to those expected for generic products of chemical origin and before marketing authorisation is granted.

British Pharmacopoeia: Monographs for biological formulated preparations The general policy of the British Pharmacopoeia Commission is that a monograph for a single dosage form should be prepared to cover each available medicinal product of a particular pharmaceutical form containing the same active pharmaceutical ingredient (API). Preparation of a product-specific monograph is avoided where possible. However, similar biological medicinal products present a different situation because, unlike other APIs produced by chemical synthesis, the structures, although very similar, may not be identical. This has an impact on the approach used for the preparation of pharmacopoeial specifications which depend on the degree of similarity or otherwise: whether the differences are translational or post-translational and whether or not test methodology is available to distinguish between similar biological medicinal products and the reference product.

In certain cases a single monograph may be possible for the 'reference' product and any biological medicinal products authorised subsequently whereas in other cases separate monographs may be needed. Consequently the BP Commission has acknowledged that similar biological medicinal products should be considered on a case-by-case basis as to whether a single monograph is sufficient or a group monograph, that covers more than one subsequently authorised product, or several individual monographs are needed.

BP monographs for dosage forms assist in providing an assurance on the quality expected for a medicinal product during its shelf life and provide a framework for use by the manufacturer. However, the analytical tests used are limited in their ability to detect all characteristics in a similar biological medicinal product that may affect clinical efficacy and safety. Aspects such as excipients, pH, buffers, exposure to surfaces, freezing/thawing and mechanical stresses may result in aggregation effects and/or chemical changes during formulation and storage. These may impact on the immunogenicity and clinical performance.

As with other pharmacopoeial monographs, it is recognised that revision of a published monograph for a dosage form may become necessary in order to take account of additional similar biological medicinal products as they become available. Manufacturers are encouraged to inform the BP Secretariat of revisions considered necessary and to provide constructive comments. A list of contact points in the Secretariat is to be found in Supplementary Chapter III A.

Monograph development for similar biological medicinal bulk materials and products

The following aspects are considered when elaborating monographs.

GROUP OR SINGLE MONOGRAPH

If possible, a single monograph is prepared for one or more similar biological medicinal bulk materials and products that have been granted marketing authorisations by comparison with an appropriate reference material. The following points are taken into consideration as to whether one or more monographs are prepared.

1. Active substance with a protein backbone Where the substance is a protein of known structure and amino acid sequence without modification, a single monograph, or modification of an existing monograph, for example to take account of a new method of production, may suffice.

2. Active substance with translational differences Where there is a difference in an amino acid sequence of the protein backbone separate monographs will be needed for the resulting substances whether or not similar products exist e.g. monographs for Insulin Aspart and Insulin Lispro and their relevant injection monographs. Identification methods are needed to distinguish between the structurally related active substances.

3. Active substance with post-translational modifications Substances with identical amino acid sequences in the protein backbone, but with post-translation differences, may be encompassed by one group monograph. The differences may be in the glycosylation, acetylation and/or sulfation. The erythropoietins, a family of closely-related glycoproteins, having the same amino acid sequence in the protein backbone and differences in their isoform compositions, are covered by the bulk material monograph for Erythropoietin Concentrated Solution and a single monograph for the injection.

4. Glycosaminoglycans Separate monographs are usually required e.g. for low molecular weight heparins, there is a group (family) monograph for Low-Molecular-Weight Heparins, that cross-refers to the API monographs for Heparin Sodium and Heparin Calcium and to all the low molecular weight API monographs (such as Dalteparin Sodium, Enoxaparin Sodium and Tinzaparin Sodium). Injection monographs for these three low molecular weight heparins are included in the British Pharmacopoeia.

Specific considerations for BP monographs for formulated preparations

The main considerations needed for similar biological medicinal products are equivalent to those used for other biotechnologically-produced biological formulations.

Monographs for formulated preparations are elaborated taking into account points 1 to 4 above. The monographs are prepared in line with the current BP Commission policy relating to generic products where possible, as explained in Supplementary Chapter III D, and in accord with the following statement given in the Chapter: Formulated preparations: '*The tests applied to the bulk drug substance, including those for impurities arising in manufacture of the bulk drug substance, should be applied, wherever possible - with any necessary modification - in order to demonstrate that material of pharmacopoeial quality has been used in making the formulation.*'. For elaboration of a monograph, information is sought on impurities arising from the manufacture and/or storage of the dosage form.

The requirements of the API monograph are used as a basis for the preparation of the first draft monograph for the formulated preparation. However, not all tests may be applicable, such as in the presence of excipients or when the concentration the API is low. In such situations, alternative procedures and/or methods of detection with increased sensitivity are necessary and validated alternative methods are sought from stakeholders. Any validation studies must take into account the appropriate ICH Guidelines on the validation of analytical procedures.

TEST METHODOLOGY IN MONOGRAPHS

When elaborating monographs for similar biological medicinal products consideration is given to inclusion of the test methods that are specified in the Ph. Eur. monograph for the API which are primarily as follows.

Identification Usually, two identity tests based on the unique characteristics of the product, such as molecular size, charge and structure are included together with a cross-reference to the biological or physico-chemical assay are included in the monograph. The test methodologies used in the current specific monographs for formulated preparations are predominantly reverse-phase liquid chromatography, size-exclusion chromatography, polyacrylamide gel electrophoresis and capillary electrophoresis; their inclusion depends on the characteristics of the molecule under investigation.

Tests Tests for heterogeneity, aggregation, impurities and degradation products are considered for inclusion depending on the characteristics of the API and formulated preparation. As for identification, the methodology used is predominantly reverse-phase liquid chromatography, size-exclusion chromatography, polyacrylamide gel electrophoresis and capillary electrophoresis.

More than one method may be included for the same test in circumstances where interference from an excipient may occur in the drug product. An example of this is in the monograph for Erythropoietin Injection where two methods, A and B, are given in the test for Dimers and related substances of higher molecular weight.

Bacterial endotoxins For new monographs, control is demonstrated by compliance with the requirements in the General Monograph for Substances for Pharmaceutical Use. Alternatively, where validated, a monocyte-activation test or recombinant factor C test may be used. A test is included in a monograph only where a specific method has to be described; in these instances, no limit is specified.
For existing monographs, the test (and limit) may be retained where it is an established and appropriate quality standard.

Assay The assay in the monograph for the medicinal substance is included where possible.

Supplementary Chapter X

Supplementary Chapter on the use of Analytical Quality by Design concepts for analytical procedures

This supplementary chapter is intended to provide non-mandatory information that may be of use to all analytical scientists when applying the principles of Analytical Quality by design to the development of analytical methods.

1. Introduction

This chapter describes some principles for the application of enhanced science- and risk-based approaches to Analytical Methods. These approaches have been described as Analytical Quality by Design (AQbD)[1] and this chapter introduces some practical guidance intended to be helpful to analytical scientists. The chapter covers:

- A discussion of Quality Risk Management (QRM)
  - Risk identification tools: Ishikawa/Fishbone
  - Risk analysis tools: FMEA
  - Risk evaluation and control
- Establishment of method understanding
  - Systematic method development and evaluation
  - Experimental design
  - Statistical approaches to support experimental design
- Analytical control strategy and ongoing trending of analytical methods

Prior to the application of these concepts, the purpose of the analytical procedure should be well defined and understood. The required performance of the method should be defined before undertaking QRM processes and method understanding activities. See Appendix III. *Chromatographic Separation Techniques* for specific guidance on system suitability requirements for a chromatographic procedure.

Application of any of the concepts described in this supplementary chapter can support both the development of validation or qualification of robust analytical methods (pharmacopoeial or *alternative methods*), and also the use of these methods during the product lifecycle to assure the quality of a particular drug substance or its pharmaceutical preparation.

Some of the terms used in this supplementary chapter carry different meanings which depend on their application. Where the following words are stated in this chapter, the intended meaning is as follows:

Robustness Effects of changes to the procedure-related method parameters on the performance of the method

Variable Any aspect of a procedure which may cause variance.

Parameter A Variable specifically related to the analytical method, eg: (HPLC Column temperature, solution concentration etc...)

Procedure Entire process, encompassing the method resulting in a reportable value. This may also detail a study design, a sampling plan, an analytical replication strategy[2], and calculations.

Method The operational components comprised of instrumentation, reagents, standards, sample preparations, calibrations, controls, and suitability criteria.

OFAT (One Factor At a Time) An experimental design process which adjusts a single parameter in a stepwise fashion to learn the effect that this parameter has on the performance of a method or process.

Reportable Value The numerical value/s obtained through following set procedures. The reportable value is the final result of the analytical procedure that is to be compared to the acceptance criteria of the specification

AQbD is an evolving area of analytical science and this supplemental guidance chapter will be updated in future editions of the BP. Additional guidance on the application of the concepts to pharmacopoeial methods and their role within the analytical method lifecycle will be included as the principles become more fully conceptualised.

2. Background

Quality by Design (QbD), as defined in ICH Q8, is a 'systematic approach to development that begins with predefined objectives and emphasises product and process understanding and process control, based on sound science and quality risk management'. Principles described in ICH guidelines Q8[3], Q9[4], Q10[5] and Q11[6] can enhance achieving the desired quality of the drug substances and medicinal product, and application of the more systematic approaches described in these guidelines, including defining a control strategy, could facilitate continual improvement and innovation throughout the product lifecycle.

The development and control of an analytical method across the product lifecycle is a key element of the overall product control strategy. A number of key concepts relating to the application of enhanced science-and risk-based approaches to analytical methods have been described as Analytical Quality by Design. The MHRA and British Pharmacopoeia have explored the practical application of these concepts to a pharmacopoeial assay procedure[7] and are applying the learnings from this study to selected individual finished product monographs where appropriate.

3. Application to the British Pharmacopoeia

In general, analytical method performance, and therefore the results generated by an analytical method, are subject to variability during routine use. Therefore it is important to understand the impact of altering method parameters (e.g., temperature, solvent composition, etc. for an HPLC method) on the results generated by the method, as well as the effect of typical changes in method conditions that can occur over

time and across laboratories (i.e., instrument type/design, reagent quality, sample shakers, analyst training, etc.).

Pharmacopoeial methods are intended to be applicable to a wide range of available formulations. This process often requires a review of registered methods to ensure they are suitable for pharmacopoeial use

The aim of the MHRA's case study was to demonstrate that AQbD can be used to ensure robust and fit-for-purpose methods are included in the BP. The case study achieved these aims and showed the value of the application of AQbD in building quality and efficiency into monograph development.. The BP is continuing to further investigate the principles to a range of pharmacopoeial procedures.

The principles discussed in sections 4, 5 and 6 are intended as complimentary, supplemental information to that included in Supplementary Chapter I. *Basis of Pharmacopoeial Requirements* and Supplementary Chapter III *C. Monograph Development: Guidance to Manufacturers.*

The concepts elaborated in this chapter may help to verify that a published pharmacopoeial method is fit-for-purpose and can be used for the specific product being examined.

The principles and practices discussed in this Supplementary Chapter can be used alone or in combination where their application will add value to the work of the analyst or organisation.

4. Quality Risk Management for Analytical Procedures

The process of building method understanding begins during method development and continues through the formal validation (in line with conventional ICH Q2: Method Validation)[8], verification, method transfer exercises and routine use, including with pharmacopoeial methods. Historically, the BP has utilised risk management principles to inform the laboratory evaluation of analytical methods.

Users of the pharmacopoeia may not have prior knowledge of a given method, above and beyond what is detailed in the pharmacopoeia. Prior knowledge, such as information contained within monographs, supplementary materials in pharmacopoeias, or information in the literature can be used, if available, as Quality Risk Management (QRM) tools. These tools (See ICH Q9) provide a framework for identifying, studying and understanding the risks to method performance and the results generated by the method. The QRM tools are most effective when initiated during method development or evaluation and applied iteratively. This allows inclusion of the most recent knowledge and reassessment of risks based on any new understanding.

Method development should involve a systematic screening of method conditions, including sample preparation, to identify a set of conditions as a starting point for further evaluation via risk assessments and the QRM process. In the case of a compendial method where formal method development may have been performed by the collaborating manufacturer or by an external laboratory, initial screening of method conditions (for example, screening Design of Experiments (DoEs) – see section 5) can aid in identifying conditions to which the method is sensitive and inform the subsequent risk assessment process. For certain procedures, generic methods may be found suitable and specific method development data may not be available.

4.1. Quality Risk Management

The ICH Q9 'Quality Risk Management' guideline, which reached Step 4 in 2005, noted that while there were some limited examples of the use of quality risk management (QRM) in the pharmaceutical industry, QRM could make a greater contribution and be a valuable component of an effective quality system. One specific area where risk management approaches are being used extensively is in the development of robust control strategies for manufacturing processes. Risk management principles can also be used to develop control strategies for analytical methods. Adopting a risk-based approach ensures that controls applied to analytical methods are focussed on those parameters that are most likely to impact the reliability of the analytical result.

4.2. Risk Identification

The risk process begins by systematically identifying the potential variables associated with the analytical procedure. It is useful to perform a structured, theoretical and practical "walkthrough" of the procedure to identify and record all the steps involved. Process mapping and flow charts tools can be used to provide a pictorial presentation of all of the steps involved (figure 1).

For complicated procedures it can be useful to break the steps down into different "unit operations" eg sampling, measurement, reporting etc.

Based on the process map, each of the steps in the procedure is reviewed and parameters that could potentially vary are identified. Tools such as an Ishikawa/Fish Bone diagram can be used to facilitate categorising the risks. (Figure 2).
A platform approach could also be adopted with the use of templates for different types of analytical methods.

4.3. Risk Analysis

Risk Analysis involves estimating the risk associated with each of the variables identified in the previous step.
It considers both the likelihood that the input may vary (probability) and the impact any variation is likely to have on the reportable result (severity). Numerous tools and approaches can be used to facilitate the risk analysis step (see ICH Q9 appendices for a range of examples).

A commonly used tool for performing a quantitative analysis is Failure Mode Effects Analysis (FMEA) – an extract from an example of which is shown in Table 1.

Table 1: Example FMEA extract

Variable	Severity (1 = Low, 5 = High)	Probability of variation (1 = Low, 5 = High)	Risk score
% Acetonitrile in dissolving solvent	3	4	12
Sonication Time (mins)	4	3	12
% Acetonitrile in the mobile phase	3	4	12
Wavelength	4	2	8
% Humidity	1	5	5
Equilibration time	1	2	2

[8] *ICH Q2(R1) - Validation of Analytical Procedures: https://database.ich.org/sites/default/files/Q2%28R1%29%20Guideline.pdf*

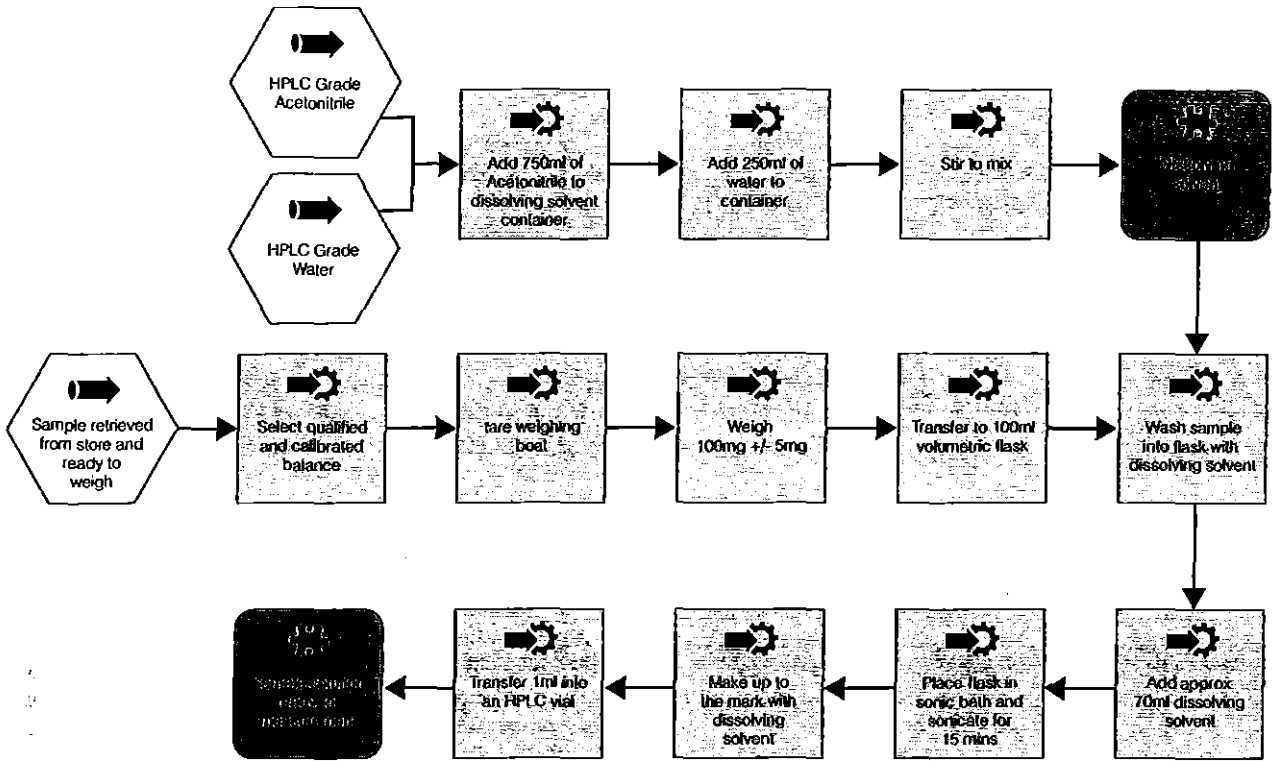

Figure 1[9] – Example of process map for an HPLC analysis

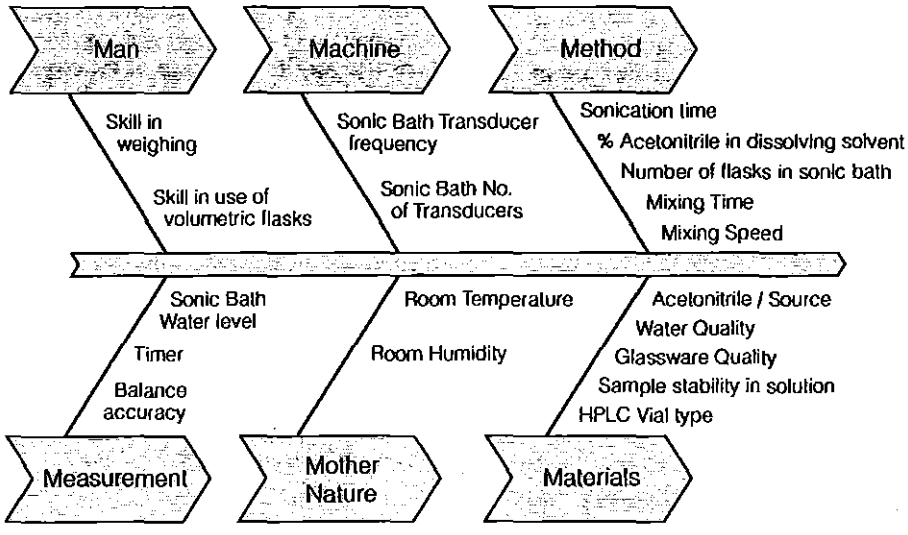

Figure 2[10] – Example of Ishikawa/Fish Bone diagram for sample preparation for HPLC Analysis

FMEA estimates are made for each input variable with respect to the probability (likelihood) of variation and the impact (severity) on the reportable result. As with identifying potential variables, the effectiveness of the risk assessment step is heavily dependent on the knowledge available to support the estimates made. Where the knowledge of the impact of a variable may have on the accuracy and/or precision of the reportable result is limited, experimental studies should be performed to provide this understanding. Design of Experiments (DoE) is an approach that can be used to identify effects of variables (separately and in combination) and minimise the experimental work involved in obtaining the necessary knowledge. When using an FMEA approach it is useful to treat it as an iterative process and update the assessment as more knowledge and understanding becomes available.

4.4. Risk Evaluation and control

Once the risk associated with each input variable is understood, an evaluation of the required controls is performed. These controls should focus on the variables which are most likely to impact the reportable result and reduce the variability and/or mitigate the impact of any variation. This is the first step in building an analytical control strategy for a method (see section 5.1). When using

[9] *see figure 6 of USP 42(5) Stimuli to the revision process: Analytical control strategy: https://www.usp.org/sites/default/files/usp/document/get-involved/stakeholder-forums/stimuli-articles-analytical-control-strategy-analytical-target-profile-2016-10-13.pdf*

[10] *see figure 7 of USP 42(5) Stimuli to the revision process: Analytical control strategy: https://www.usp.org/sites/default/files/usp/document/get-involved/stakeholder-forums/stimuli-articles-analytical-control-strategy-analytical-target-profile-2016-10-13.pdf*

an FMEA approach this means identifying steps that will reduce the probability score so that the overall risk is reduced. Once such steps have been identified, the risk score should be reassessed with suitable controls in place.

Where the probability of variation cannot be reduced significantly, consideration should be given to whether there are opportunities to detect unacceptable variation before the reportable result is generated, such that it can be invalidated. For example, if batch-to-batch variation in chromatographic packing material cannot be eliminated, a resolution check may be introduced to detect potential impact on the ability of the method to resolve and accurately quantify analytes (see section 6.2 for trending concepts). Ideally "system suitability" tests can help to mitigate known risks by assuring that the method is performing as designed.

5. Establishing method understanding

An analytical control strategy is a planned set of controls to ensure the reportable value obtained from procedures are fit-for-purpose for the product, derived from an understanding of the analytical procedure and the management of risk.

The effectiveness of a risk assessment, and ultimately the analytical control strategy for a given method, is related to the level of understanding of the relationship between method parameters and the method output, i.e. the result for the specific product being tested. Section 4 sets out approaches to ensuring method understanding that can be adopted throughout the product lifecycle.

The MHRA and British Pharmacopoeia case study has been used to illustrate how the Pharmacopoeia may apply AQbD concepts when assessing a method's suitability for compendial use. It is not expected that all of the concepts are used for assessment of the suitability of every method.

5.1. Systematic method development and evaluation

In support of risk assessments, experimental studies are conducted to understand the impact of method parameters and environment on method performance. These experimental studies are usually designed to evaluate:

- the influences of deliberate variations in procedure-related method parameters (solvent strength, pH, sample concentration, etc.)
- the influences of 'noise' factors (analyst, column batch etc.) which typically cannot be, or are preferred not to be controlled.

When investigating deliberate variations in procedure-related method parameters multifactor empirical modelling (e.g., DoE's) is generally preferred compared to One factor at a time (OFAT) experiments, though OFAT may be appropriate in some cases. Mechanistic modelling, or combined mechanistic and empirical modelling, have the potential to reduce the experimental burden and can be employed when demonstrated to be appropriate. The effect of method changes on the results generated by the method can be considered in addition to other key method attributes (e.g. resolution, sensitivity, accuracy, etc.) to understand method performance and to optimize method conditions.

'Noise' factors can often be the root cause of issues arising through the routine use of analytical methods. It is possible that not all of these factors can be studied experimentally, however through the systematic investigation of those that can be studied, the risk of method failure may be reduced. Investigations of noise factors typically require designs applicable to parameters with discrete values (e.g. column temperature) and are used to challenge the method and understand their effect on precision in the longer term.

Identification of a noise factor having a large effect on the variation of test results may indicate that control of additional method parameters is needed.

The case study also investigated noise factors as it involved the investigation of multiple product suppliers, which is mainly applicable to pharmacopoeial use. A more typical example of the study of noise factors in provided in section 5.2. By necessity, the case study explored these concepts extensively and it would not necessarily be appropriate or effective to uniformly apply for all methods.

5.2. Utilising method development tools and statistical analysis

Analytical method parameters are factors related to the operation of the method which can be specified within a continuous range or at controllable, unique levels. Experimentation which uses fractional factorial designs (DoEs) to develop general purpose (linear) models describing the effect of changes in analytical method parameters is outlined below. These models are used to identify and/or confirm (typically) a setpoint and ranges for analytical method parameters, which in combination assure robustness. It is possible to define a wider operating region throughout which the method may be used but this is not typically done.

As part of the practical application of AQbD to the pharmacopoeial Assay procedure, DoEs were performed to investigate sample extraction, chromatography and solution stability. The two-level fractional factorial design for the investigation of four mobile phase factors is illustrated in Figure 3. A full two-level factorial design consists of all the combinations of chosen low and high levels of the parameters as represented by the corners of the cubes. A fractional factorial design uses a specific set of points (fraction) - as shown by the solid circles in this example. Here it is a half fraction because the design uses 8 out of the possible 16 (2^4) combinations of low and high levels for the four factors. In addition, centre points (mid value between low and high and often the planned setpoint for the method) are used to estimate variability at the same conditions and assess whether a linear model in the parameters is adequate. Fractional factorial designs are very effective due to hidden replication (half of the factorial points are performed at a level of a parameter rather than just one for OFAT experiments) and it is not necessary to run all factorial combinations (an adequate model is usually obtained from the effects of single factors or interactions between two).

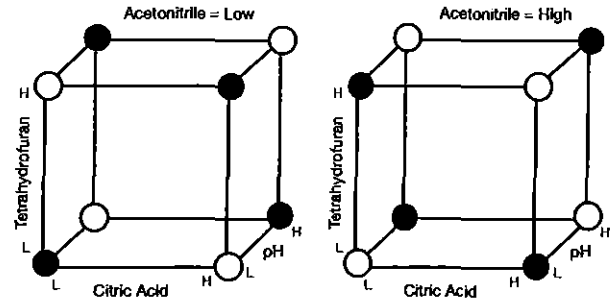

Figure 3: Fractional factorial design (solid circles) for four factor mobile phase experiment

Whilst Figure 3 illustrates the concept, a design listing (see Table 2) is used to describe the design. It is useful for any number of parameters to be investigated and describes the

Table 2: Design Listing for Mobile Phase Composition DoE

		Factor A	Factor B	Factor C	Factor D	Response 1
Run Order	Space Type	Citric Acid (g)	pH	Tetrahydrofuran (mL)	Acetonitrile (mL)	Atorvastatin Tailing Factor
1	Factorial	8.66	3.8	130	175	1.12
2	Factorial	8.66	3.8	70	95	1.05
3	Centre	9.62	4	100	135	1.07
4	Factorial	10.58	3.8	130	95	1.06
5	Factorial	10.58	4.2	70	95	1.06
6	Factorial	8.66	4.2	130	95	1.1
7	Factorial	8.66	4.2	70	175	1.09
8	Centre	9.62	4	100	135	1.1
9	Centre	9.62	4	100	135	1.08
10	Factorial	10.58	4.2	70	175	1.06
11	Factorial	10.58	4.2	130	175	1.17
12	Centre	10.58	4	100	175	1.08

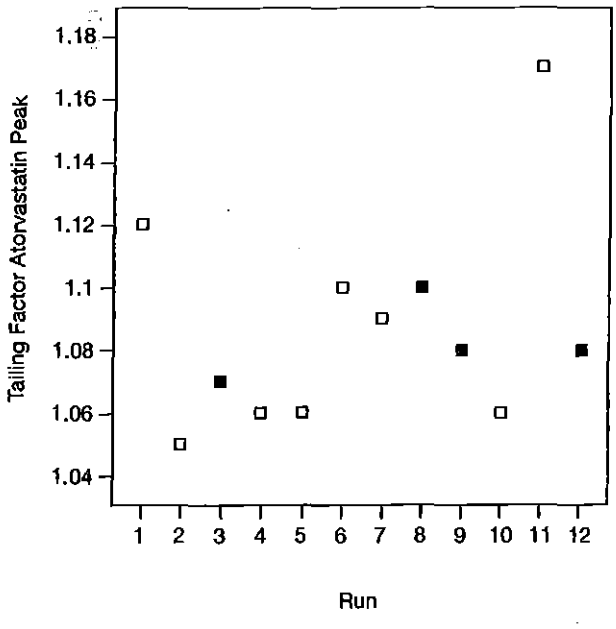

Figure 4: Tailing factor for the Atorvastatin peak plotted against run (centre points are shaded)

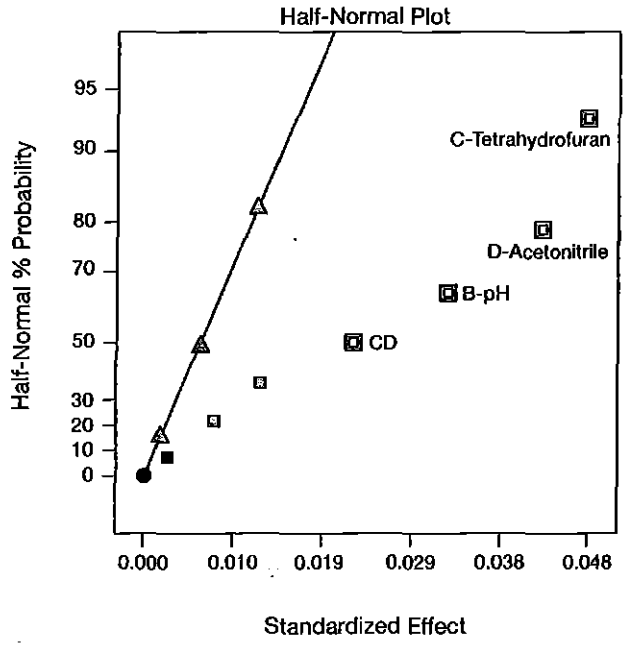

Figure 5: Half-normal plot for model terms for Tailing Factor for Atorvastatin peak

random order in which the design is to be run. The method is operated under the condition for each run in turn and the results recorded. For illustration, the tailing factor response is listed in Table 2 and plotted in Figure 4.

The acceptance criteria for the tailing factor of the Atorvastatin peak is ≤ 1.2. If all the results from the DoE runs had been far below the acceptance criteria a statistical analysis may not be required, though if there is a wide range between the factorial points it is useful to understand which parameters may cause this. Here it is seen that one run had a value of 1.17. Although this meets the criteria it is possible that a combination of factor settings not explored in the design may exceed 1.2. Also, it is noted that repeating the same conditions will give variable results (see variation in the centre points). Thus, a statistical analysis is desired.

The first step in the statistical analysis is to identify which are the major parameter effects. Figure 5 illustrates one tool – a half-normal plot. Model terms are selected (represented by small squares) which are greater than background noise (to the right of the line through the triangles which represent the background variability estimated from the four centre points). Parameters Tetrahydrofuran (C), Acetonitrile (D) and pH (B) have the largest effects. The fourth term selected is an interaction between two parameters. Statistically it is not possible from the design to know whether this is the interaction between A and B or C and D. Since C and D are the largest effects and this makes analytical sense the CD interaction was also included in the model. The next term was not included in the model. It was not statistically significant, it is small and the design cannot distinguish between the two possible interactions, BC and AD.

A statistical analysis will typically assess statistical significance of terms identified for inclusion in the model and assess

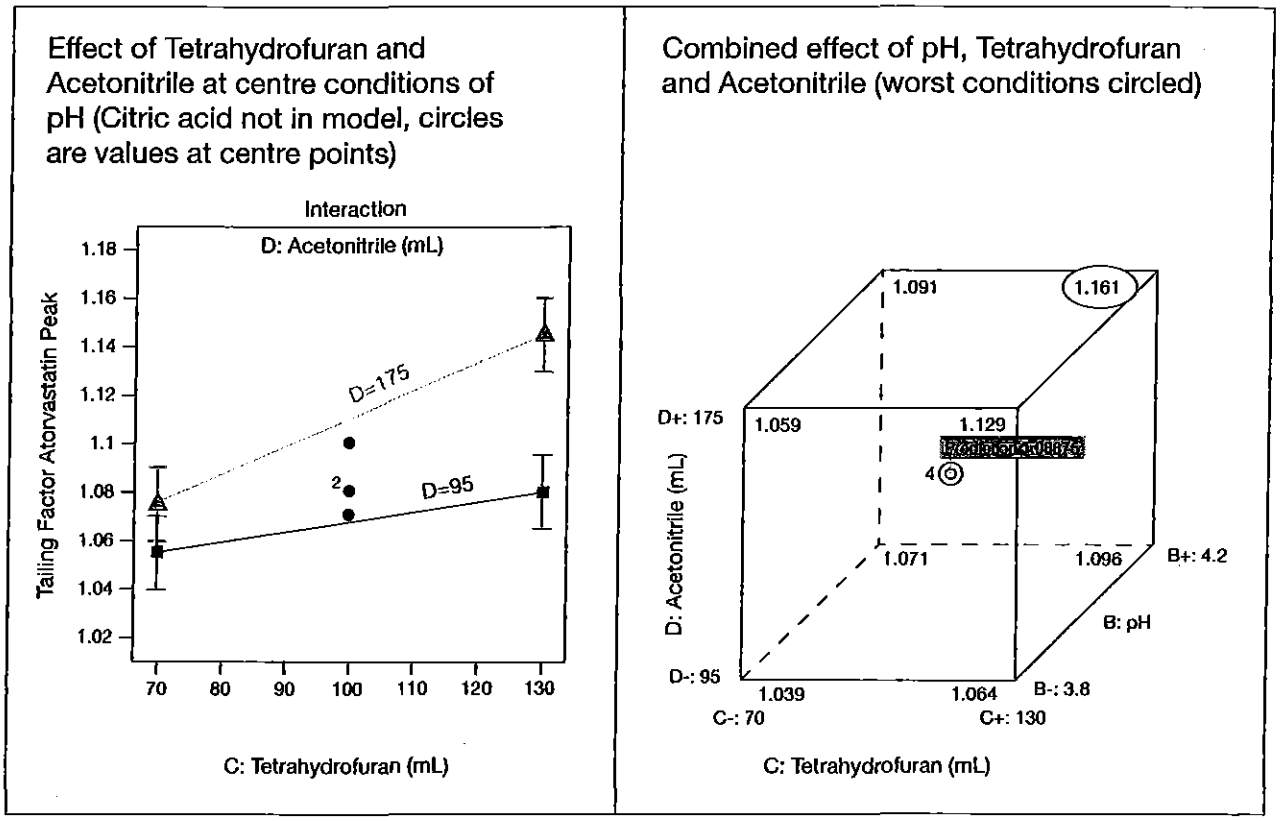

Figure 6: Effect of Parameters on Tailing Factor.

assumptions used in the modelling (linear model is adequate, residuals are normally distributed and no outliers are observed). The model is then used to predict the effect of method parameters. Figure 6 shows the effect of Tetrahydrofuran, Acetonitrile and pH on the mean tailing factor.

Various system suitability responses were examined (tailing factors, efficiencies, resolution, retention times). In addition, the effect of method parameters on %Assay may be examined. The %RSD of %Assay over the combinations investigated may be useful in addition to a similar analysis to that applied to the tailing factor.

If the model only contains linear terms for parameter effects and any interactions then it is sufficient to establish that results are acceptable at the limits of the parameter ranges (in combination). If the model is more complex than linear e.g. non-linear, or a mechanistic model, then evaluation within the parameter ranges may be required. If a model with linear terms is insufficient, response surface designs may be used to include quadratic terms to model curvature. If the results are not acceptable at the limits of the parameter ranges, it may be possible to use the model to predict ranges within those investigated, in which the method could be satisfactorily operated or further experimentation may be required to identify an acceptable region. Where mechanistic models are available (e.g. chromatographic in-silico modelling systems), designs appropriate to the model should be applied (and in some cases little experimentation may be required).

Examples in literature[11] provide a very comprehensive explanation of full and fractional factorial designs and the application of experimental design to analytical methods (focused on chromatography)[12]. The design should be carefully chosen to meet the purpose of the study – is the design intended to identify parameters having an effect or optimise a method over a wide parameter region, or to assess robustness around the setpoint. A limited evaluation of the data could be gained from plotting the data and calculating means at the low and high levels for each factor to establish which has the largest effect. However, to understand interactions between factors, assess statistical significance (i.e. that effects seen are likely not to be due to chance) and produce predictions, software that can fit general purpose models with linear and quadratic terms in the parameters is likely to be required. Software which combines functionality for designing factorial type experimentation with corresponding statistical analysis is particularly helpful. The software may be integrated with a chromatographic system, focused on designed experiments (either entirely or a specific module) or more general statistical software.

5.3. Assessment of variation in method operating conditions

The variations in method operating conditions considered here are typical changes in method conditions that can occur over time and across laboratories, (i.e., instrument type, reagent quality, sample shakers, analyst training, etc.). These are changes which are not specified or controlled as method parameters- "noise factors". Studies are designed with the purpose of challenging the method and to understand their effect on precision in the longer term. Noise factors having a large effect on the precision can be identified and further investigated with the aim of improvement and/or control

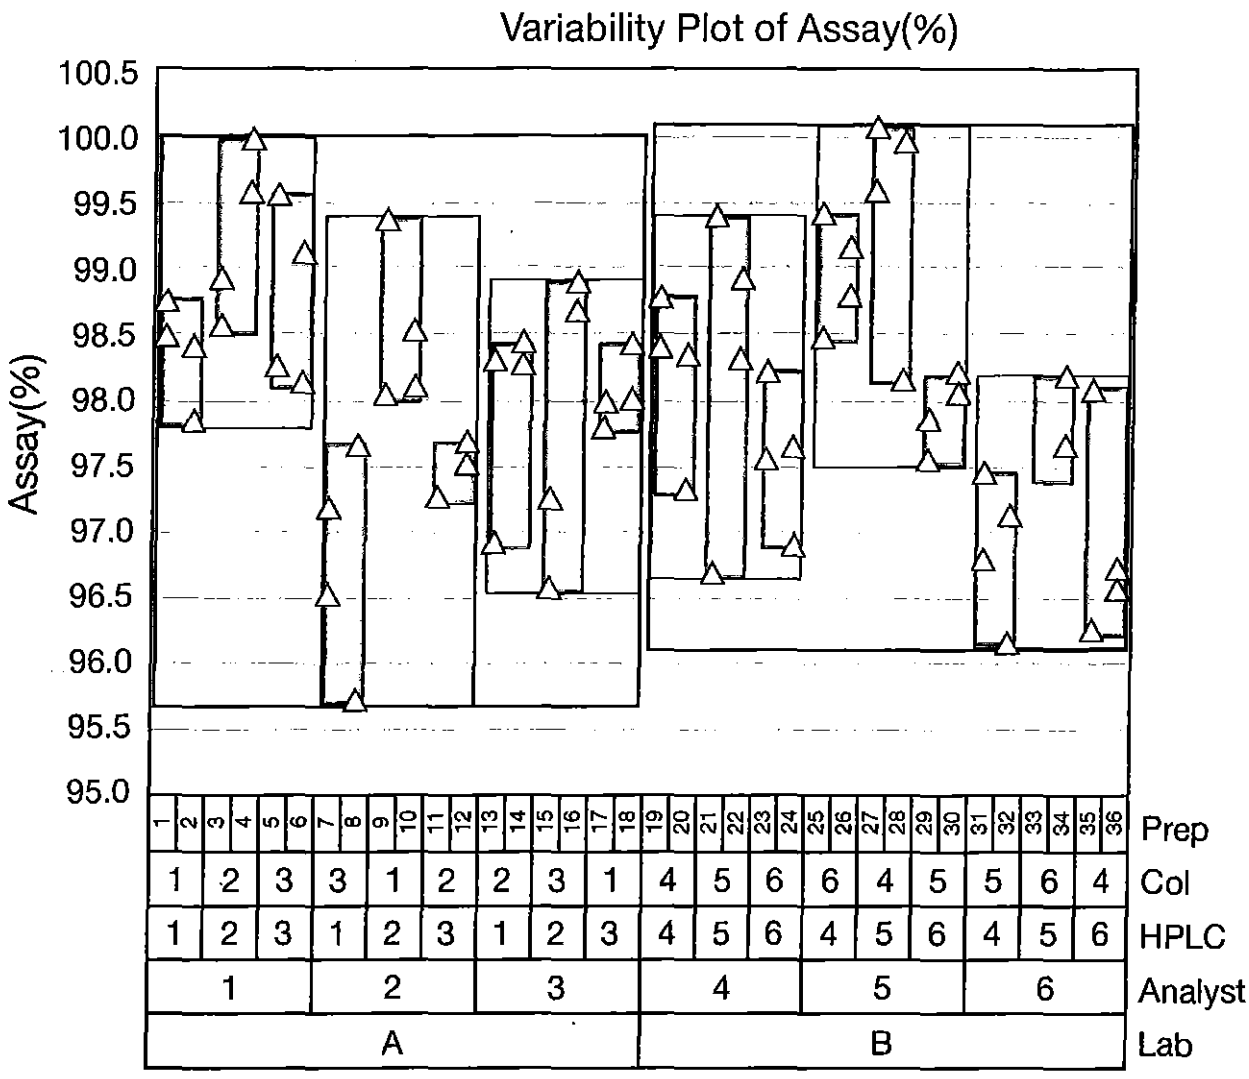

Figure 7: Plot of assay results from a study of potential noise factors

where possible. In contrast to the designs for assessing the effect of analytical method parameters which predominantly evaluate continuous factors, the focus of these studies is on factors with discrete levels, uncontrolled in the method description e.g. analyst. It is often useful to perform such a study as part of a method transfer as the two activities can be combined saving resource and the use of two labs provides more challenge to the method.

Figure 7 shows an example study – the design should be chosen based on the risk assessment and the practicalities which apply. The factors and chosen levels can be seen at the bottom of the plot. Factors may be "crossed" or "nested" in such a design. In the example analyst, HPLC and column (col) are nested within lab, i.e. an analyst only occurs at one site. Preparation level is nested within each analyst, HPLC and column combination and two injections are performed for each prep. However, analyst, HPLC and column are crossed with each other i.e. an analyst uses more than one HPLC equipment. It is desirable to use a reasonable number of levels for all factors in the design (not just preps and injections) in order to better allow any effects/variation due to the factor to manifest itself during the study (acknowledging that there will be practical constraints).

The statistical analysis typically consists of visualising the data and fitting models to estimate the variation due to each noise source or their interactions (variance components). This is usually a variance components or mixed model analysis.

Figure 8 shows the results of a statistical analysis with the estimated variance components shown for the various factors. It is seen that the injection variation and analyst variation contribute most to the variation. Some variability due to HPLC is also seen but the column and preparation contribute very little variability.

Figures 7 and 8 show the clear benefits of using data visualisation to identify the cause/s of variation. Figure 5 appears to show variation at all levels other than between laboratories. This indicates a systematic issue with the methodology, which is being replicated from Lab A to Lab B. Digging deeper, figure 6 shows that the main proportion of variance is from injection to injection and analyst to analyst, rather than preparation, column or HPLC instrument. This type of analysis can be key to both identifying issues with procedures during validation as well as during a root cause analysis on existing procedures, where an issue may have occurred.

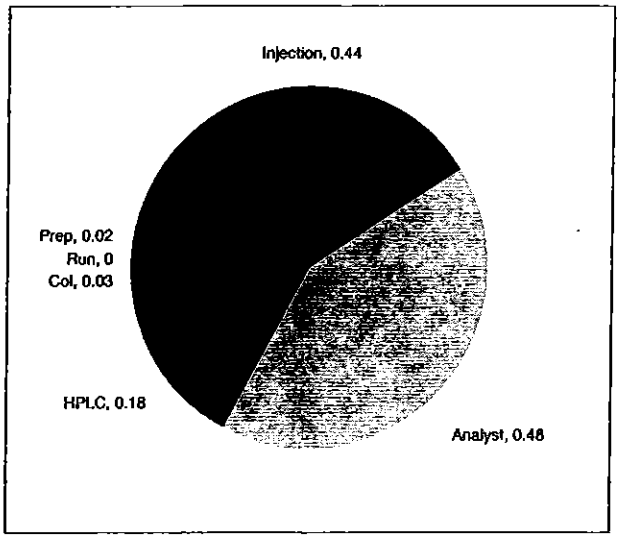

Figure 8: Variance components from various noise factors

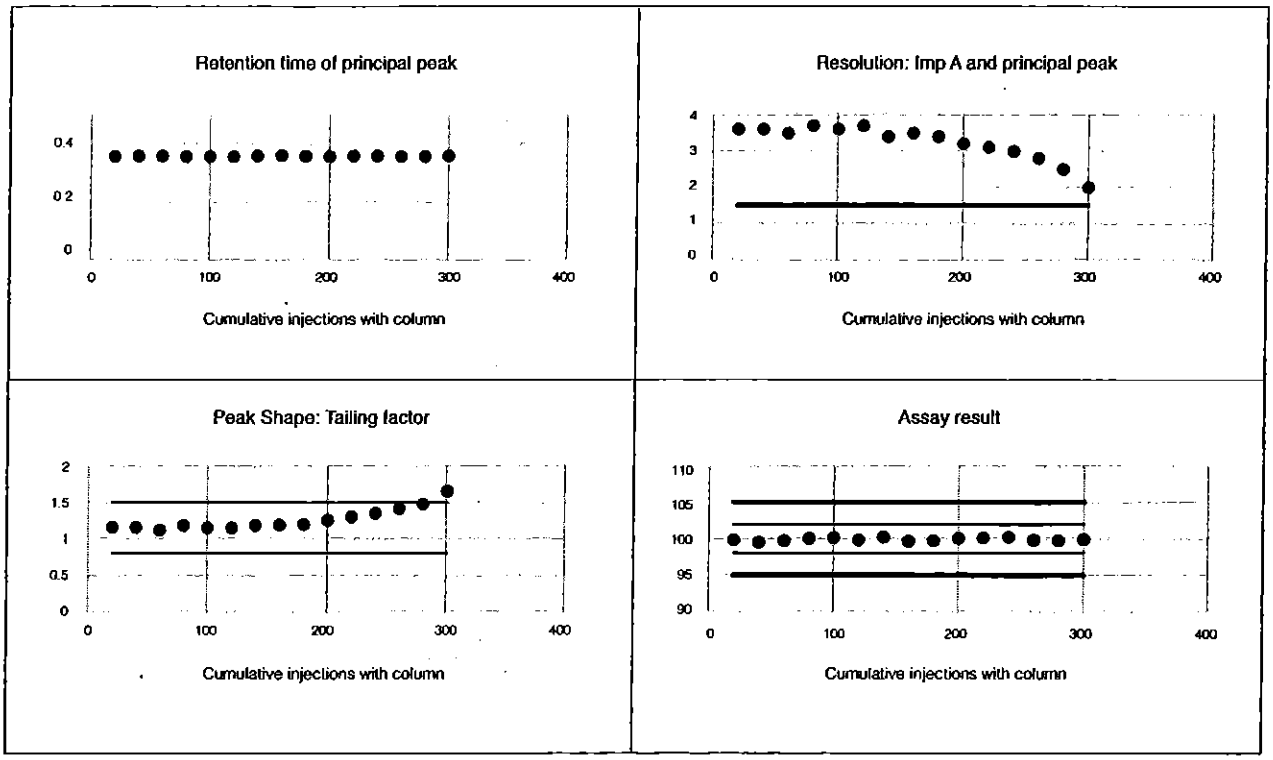

Figure 9 – Example of control charts monitoring different aspects of ongoing method performance

The precision of the analytical measurement can be calculated by summing the variance estimates, taking into account any replication used in providing the reported result. For example, the intermediate precision (variance) for a reported result from the mean of two preparations would be found by summing the variance components for between analytical run sources of variability (Analyst, HPLC, Column, Run) and half of the preparation and injection components of variance. Thus:

$$SD = \sqrt{0.48 + 0.18 + 0.03 + 0 + \frac{0.02}{2} + \frac{0.44}{2}} = 0.96$$

The overall mean of the results was 98.0 giving:

$$\%RSD = 100 \times \frac{0.96}{98.0} = 0.98\%$$

Additional literature sources provide further details and examples of such studies[13]. Performing the study and plotting the data can be useful in its own right. However, to perform the statistical analysis to gain most information from the study, software that can fit mixed models is likely to be required (usually Restricted Maximum Likelihood – REML is used).

[13] *https://pubmed.ncbi.nlm.nih.gov/21889624/ - Borman, Phil J., Marion J. Chatfield, Ivana Damjanov, and Patrick Jackson. "Method ruggedness studies incorporating a risk-based approach: a tutorial." Analytica chimica acta 703, no. 2 (2011): 101-113.*

6. The analytical control strategy and its role in ongoing monitoring of method performance.

6.1. Analytical Control Strategy

ICHQ10 defines a control strategy as: *a planned set of controls derived from product and process understanding, that assures process performance and product quality. The controls can include parameters and attributes related to drug substance and drug product materials and components, facility and equipment operating conditions, in process controls, finished product specifications and the associated methods and frequency of monitoring and control.*

Clearly this definition applies to manufacturing processes however the idea of a control strategy for analytical methods mirrors the above if the output of the process is regarded as the reportable result rather than a drug product. The key point is that the control strategy should be comprehensive and consider all of the materials used, operating conditions, system suitability checks, etc that are required to assure the quality of the reportable result.

Sections 4 and 5 detail the concepts one may adopt to produce an analytical control strategy built on deep method and product understanding. The MHRA case study confirmed that to complete a suitable control strategy for the atorvastatin tablets pharmacopoeial Assay method was to follow system suitability criteria in the form of a minimum resolution between a critical pair (Atorvastatin and close eluting related substance).

For a pharmacopoeial method, the chromatographic conditions and permissible adjustments set out in Appendix III Chromatographic Separation Techniques are complementary to the analytical control strategy developed in line with the processes described in this supplementary chapter.

6.2. Ongoing monitoring of methods

Monitoring of the results of analytical methods helps to build process capability insights. However, additional trending of a range of different method outputs is another strategy used to identify areas of risk and alert users to take action before method failure.

Monitoring an analytical method is helpful since it can alert users to trends. There are different ways to conduct monitoring – trending results, control sample results, performance attributes (e.g. retention time of specific analytes, peak shape of principal peaks and more). Monitoring of measurements for reference or standard material repeatably analysed over time may also be useful.

Figure 9 is a simple model of additional parameters that may require trending through the lifetime of a method (or in this case, an individual column). Here you can see an inverse relationship between the resolution of critical pair and the peak shape of the drug substance. In this instance, an increase in peak tailing is causing a loss in separation between the drug substance and a major impurity. Ultimately, the Assay value here is unaffected, however the resolution is heading towards a failure of system suitability criteria, as is the peak shape.

The BP appreciates that the modelling and subsequent decision point to change a column, detailed above, is a small and distinct use for the monitoring of an analytical method. More detailed monitoring and change is likely to add benefit to users[14] and may be built on in future iterations of this supplementary chapter. It is noted that statistical techniques may also be useful in monitoring the performance of system suitability and/or reference measurements over time.

Petroleum Rectificatum for Homoeopathic Preparations, IV-594
Petroleum Spirit, V-A115
Petroleum Spirit (boiling range, 40° to 60°), Aromatic-free, V-A115
Petroleum R1, Light, V-A115
Petroleum R2, Light, V-A115
Petroleum R3, Light, V-A115
Petroleum R4, Light, V-A115
PFU, Definition of, I-30, II-30, III-30, IV-30, V-30
pH Indicator Strip, V-A115
pH of Solutions, Approximate, V-A289
pH Values, Determination of, V-A289
Pharmaceutical Preparations, III-39, IV-39
Pharmaceutical Preparations, Microbiological Quality of, V-A750
Pharmaceutical Use, Control of Impurities in Substances for, V-A820
Pharmaceutical Use, Glass Containers for, V-A636
Pharmaceutical Use, Substances for, I-39, II-39
Pharmacopoeial Calculations, V-A896
Pharmacopoeial Harmonisation, V-A790
Pharmacopoeial Quantitative Analysis, V-A896
Pharmacopoeial Requirements, I-xxix
Pharmacopoeial Requirements, Basis of, V-A731
α-Phellandrene, V-A115
Phellodendron Amurense Bark, IV-418
Phellodendron Chinense Bark, IV-419
Phenacetin, V-A115
Phenanthrene, V-A115
Phenanthroline Hydrochloride, V-A116
Phenazone, II-580, V-A116
Phenelzine Sulfate, II-581
Phenelzine Sulphate, *see Phenelzine Sulfate*
Phenelzine Tablets, III-1167
Pheneturide, V-A117
Phenindione, 114, II-582
Phenindione Tablets, III-1168
Pheniramine Maleate, II-584
Phenobarbital, 114, II-585
Phenobarbital Elixir, III-1169
Phenobarbital Injection, III-1170
Phenobarbital Oral Solution, *see Phenobarbital Elixir*
Phenobarbital Oral Solution, Paediatric, III-1171
Phenobarbital Sodium, II-586
Phenobarbital Tablets, III-1172
Phenol, II-588, V-A116
Phenol and Glycerol Injection, III-1173
Phenol in Immunosera (Antisera) and Vaccines, V-A524
Phenol Injection, Aqueous, III-1173
Phenol Injection, Oily, III-1173
Phenol, Liquefied, II-589, V-A116
Phenol Red, V-A116
Phenol Red Solution, V-A116
Phenol Red Solution R1, V-A116
Phenol Red Solution R2, V-A116
Phenol Red Solution R3, V-A116
Phenoldisulfonic Acid Solution, V-A116
Phenoldisulphonic Acid Solution, *see Phenoldisulfonic Acid Solution*
Phenolphthalein, II-589, V-A116
Phenolphthalein Paper, V-A116
Phenolphthalein Solution, V-A116
Phenolphthalein Solution R1, V-A116
Phenolphthalein-Thymol Blue Solution, V-A116
Phenolsulfonphthalein, II-590
Phenolsulfonphthalein, *see Phenol Red*
Phenolsulphonphthalein, *see Phenolsulfonphthalein*
Phenothiazines by Thin-Layer Chromatography, Identification of, V-A233
Phenothiazines, Related Substances in, V-A233
Phenoxyacetic Acid, V-A116
2-Phenoxyaniline, V-A116
Phenoxybenzamine Capsules, III-1174
Phenoxybenzamine Hydrochloride, 115, II-591, V-A116
2-Phenoxyethanol, V-A116
Phenoxyethanol, II-592
Phenoxyethanol, *see 2-Phenoxyethanol*
Phenoxymethylpenicillin, II-593
Phenoxymethylpenicillin (Benzathine) Tetrahydrate, II-597
Phenoxymethylpenicillin Oral Solution, III-1175
Phenoxymethylpenicillin Potassium, II-595
Phenoxymethylpenicillin Tablets, III-1177
Phentolamine Injection, III-1178
Phentolamine Mesilate, II-599
Phenyl Benzoate, V-A117
Phenyl Isothiocyanate, V-A117
Phenyl Silica Gel for Chromatography, V-A135
Phenylacetic Acid, V-A117
4-Phenylacetophenone, *see 4-Acetylbiphenyl*
trans-3-Phenylacrylic Acid, *see Cinnamic Acid*
L-Phenylalanine, V-A117
Phenylalanine, II-600
Phenylalanine, *see L-Phenylalanine*
1-(phenylazo)naphthalen-2-ol, *see Sudan Yellow*
o-Phenylbenzoic Acid, V-A117
Phenylbis(4-hydroxynaphthyl)methanol, *see 1-Naphtholbenzein*
2-Phenylbutanoic acid, V-A117
(2-Phenylbutanoyl)urea, V-A117
Phenylbutazone, II-602
2-Phenylbutyrylurea, V-A117
N-Phenylcarbazole, V-A117
p-Phenylenediamine Dihydrochloride, V-A117
Phenylephrine, II-603
Phenylephrine Eye Drops, III-1179
Phenylephrine Hydrochloride, II-605
Phenylephrine Injection, III-1181
Phenylephrine Injection, Intracameral, III-1182
Phenylephrine Intracameral Injection, III-1182
DL-Phenylglycine, V-A117
D-Phenylglycine, V-A117
α-Phenylglycine, *see DL-Phenylglycine*
Phenylhydrazine, V-A117
Phenylhydrazine Hydrochloride, V-A117
Phenylhydrazine Hydrochloride Solution, V-A117
Phenylhydrazine-Sulfuric Acid Solution, V-A117
Phenylhydrazine-Sulphuric Acid Solution, *see Phenylhydrazine-Sulfuric Acid Solution*
Phenylhydrazinium Chloride, *see Phenylhydrazine Hydrochloride*
Phenylmercuric Acetate, II-607
Phenylmercuric Borate, II-607
Phenylmercuric Nitrate, II-608
Phenyl(5)methyl(95)polysiloxane, V-A117
Phenyl(50)methyl(50)polysiloxane, V-A117
Phenyl(5)methyl(95)polysiloxane, Base-deactivated, V-A117
1-Phenylpiperazine, V-A117
3-Phenylpropanoic Acid, V-A117
1-Phenylpropan-2-ol, V-A117
Phenylpropanolamine Hydrochloride, II-608
3-Phenylpropenal, *see Cinnamaldehyde*
1-Phenyl-1,2,3,4-tetrahydroisoquinoline, V-A117
Phenytoin, 115, II-610
Phenytoin Capsules, III-1183
Phenytoin Injection, III-1184
Phenytoin Oral Suspension, III-1185
Phenytoin Sodium, II-611
Phenytoin Tablets, III-1186
Phloroglucide, V-A117
Phloroglucinol, II-613, V-A117
Phloroglucinol Dihydrate, II-615
Phloroglucinol Solution, V-A118
Pholcodine, 115
Pholcodine, *see Pholcodine Monohydrate*
Pholcodine Linctus, III-1187
Pholcodine Linctus, Strong, III-1188
Pholcodine Monohydrate, II-617
Pholcodine Oral Solution, *see Pholcodine Linctus*
Pholcodine Oral Solution, Strong, *see Pholcodine Linctus, Strong*

Silica Gel for Chromatography, Octadecylsilyl, for Separation of Polycyclic Aromatic Hydrocarbons, V-A134
Silica gel for Chromatography, Octadecylsilyl, Monolithic, V-A134
Silica Gel for Chromatography, Octadecylsilyl, Monolithic, End-capped, V-A134
Silica Gel for Chromatography, Octadecylsilyl, Polar End-capped, V-A134
Silica Gel for Chromatography, Octadecylsilyl, Polar-embedded, Encapsulated, V-A134
Silica Gel for Chromatography, Octadecylsilyl, Solid Core, V-A134
Silica Gel for Chromatography, Octadecylsilyl, Solid Core, End-capped, V-A134
Silica Gel for Chromatography, Octadecylsilyl, with Embedded Polar Groups, End-capped, V-A134
Silica Gel for Chromatography, Octadecylsilyl, with Extended pH Range, End-Capped, V-A134
Silica Gel for Chromatography, Octylsilyl, V-A134
Silica Gel for Chromatography, Octylsilyl and Octadecylsilyl Multi-Alkyl, V-A134
Silica Gel for Chromatography, Octylsilyl, Base-deactivated, V-A134
Silica Gel for Chromatography, Octylsilyl, End-capped, V-A134

Silica Gel for Chromatography, Octylsilyl, End-capped, Base-deactivated, V-A134
Silica Gel for Chromatography, Octylsilyl, Extra-dense Bonded, End-capped, V-A134
Silica Gel for Chromatography, Octylsilyl, Solid Core, V-A135
Silica Gel for Chromatography, Octylsilyl, Solid Core, End-capped, V-A135
Silica Gel for Chromatography, Octylsilyl, with Embedded Polar Groups, End-capped, V-A135
Silica Gel for Chromatography, Oxypropionitrilsilyl, V-A135
Silica Gel for Chromatography, Palmitamidopropylsilyl, End-capped, V-A135
Silica Gel for Chromatography, Pentafluorophenylpropylsilyl, Solid Core, End-capped, V-A135
Silica Gel for Chromatography, Phenyl, V-A135
Silica Gel for Chromatography, Phenylethyl, End-capped, V-A135
Silica Gel for Chromatography, Phenylhexylsilyl, V-A135
Silica Gel for Chromatography, Phenylhexylsilyl, End-capped, V-A135
Silica Gel for Chromatography, Phenylhexylsilyl, Solid Core, End-capped, V-A135
Silica Gel for Chromatography, Phenylsilyl, V-A135
Silica Gel for Chromatography, Phenylsilyl, End-capped, V-A135
Silica Gel for Chromatography, Phenylsilyl, End-Capped, Base-Deactivated, V-A135
Silica Gel for Chromatography, Phenylsilyl, Extra-dense Bonded, End-capped, V-A135
Silica Gel for Chromatography, Propoxybenzene, End-capped, V-A135
Silica Gel for Chromatography, Propylsilyl, V-A135
Silica Gel for Chromatography, Strong Cation-exchange, V-A136
Silica Gel for Chromatography, Strong-anion-exchange, V-A136
Silica Gel for Chromatography, Trimethylsilyl, V-A136
Silica Gel for Chromatography R1, Aminopropylsilyl, V-A132
Silica Gel for Chromatography R1, Nitrile, V-A135
Silica Gel for Chromatography R1, Octadecylsilyl, V-A135
Silica Gel for Chromatography R2, Octadecylsilyl, V-A135
Silica Gel for Chromatography R1, Octadecylsilyl, End-capped, V-A136
Silica Gel for Chromatography R1, Octadecylsilyl, End-capped, Base-deactivated, V-A136
Silica Gel for Chromatography R1, Octylsilyl, V-A136
Silica Gel for Chromatography R2, Octylsilyl, V-A136
Silica Gel for Chromatography R3, Octylsilyl, V-A136
Silica Gel for HPTLC, Octadecylsilyl, V-A136
Silica Gel for Size-exclusion Chromatography, V-A136
Silica Gel G, V-A136
Silica Gel GF_{254}, V-A136
Silica Gel H, V-A136
Silica Gel H, Silanised, V-A137
Silica Gel HF_{254}, V-A137
Silica Gel HF_{254}, Silanised, V-A137
Silica Gel OD for Chiral Separations, V-A137
Silica Gel OD for Chiral Separations, *see Silica Gel for Chiral Separation, Cellulose Derivative of*
Silicates, Reactions and Tests of, V-A305
Silicone, V-A683
Silicone Elastomer for Closures and Tubing, V-A684
Silicone Oil Used as a Lubricant, V-A683

Zinc Acetate Cutaneous Solution, Erythromycin and, *see Erythromycin and Zinc Acetate Lotion*
Zinc Acetate Dihydrate, *see Zinc Acetate*
Zinc Acetate Lotion, Erythromycin and, III-616
Zinc Acetate Solution, V-A159
Zinc Acexamate, II-1332
Zinc, Activated, V-A160
Zinc and Castor Oil Cream, III-1517
Zinc and Castor Oil Ointment, III-1517
Zinc and Coal Tar Paste, III-1518
Zinc and Hexachlorophene Dusting Powder, III-765
Zinc and Ichthammol Cream, III-1518
Zinc and Salicylic Acid Paste, III-1518
Zinc and Zinc Salts, Reactions and Tests of, V-A305
Zinc Chloride, II-1334, V-A160
Zinc Chloride Solution, Iodinated, V-A160
0.05M Zinc Chloride VS, V-A168
Zinc Chloride–Formic Acid Solution, V-A160
Zinc Cream, III-1515
Zinc Gluconate, II-1334
Zinc Iodide, V-A160
Zinc Iodide and Starch Solution, V-A160
Zinc Ointment, III-1516
Zinc Ointment, Coal Tar and, III-1394
Zinc Oxide, II-1335, V-A160
Zinc Paste, Compound, III-1516
Zinc Powder, V-A160
Zinc Shot, V-A160
Zinc Standard Solution (5 mg/mL Zn), V-A172
Zinc Standard Solution (5 ppm Zn), V-A173
Zinc Standard Solution (10 ppm Zn), V-A173
Zinc Standard Solution (25 ppm Zn), V-A173
Zinc Standard Solution (100 ppm Zn), V-A172
Zinc Stearate, II-1336
Zinc Sulfate, V-A160
Zinc Sulfate Capsules, III-1516
Zinc Sulfate Eye Drops, III-1516
Zinc Sulfate Heptahydrate, II-1337
Zinc Sulfate Heptahydrate, *see Zinc Sulfate*
Zinc Sulfate Hexahydrate, II-1337
Zinc Sulfate Injection, III-1517
Zinc Sulfate Lotion, III-1517
Zinc Sulfate Monohydrate, II-1338
Zinc Sulfate Tablets, III-1517
0.1M Zinc Sulfate VS, V-A168
Zinc Sulphate, *see Zinc Sulfate*
Zinc Sulphate Capsules, *see Zinc Sulfate Capsules*
Zinc Sulphate Eye Drops, *see Zinc Sulfate Eye Drops*
Zinc Sulphate Injection, *see Zinc Sulfate Injection*
Zinc Sulphate Lotion, *see Zinc Sulfate Lotion*
Zinc Sulphate Tablets, *see Zinc Sulfate Tablets*
Zinc Undecenoate, II-1338
Zinc Undercylenate, *see Zinc Undecenoate*
Zincum Sulfuricum, V-A705
Ziprasidone Hydrochloride Monohydrate, II-1339
Ziprasidone Mesilate Trihydrate, II-1341
Zirconium Standard Solution (1 g/L Zr), V-A173
Zirconyl Chloride, V-A160
Zirconyl Nitrate, V-A160
Zirconyl Nitrate Solution, V-A160
(*Z*)-Ligustilide, V-A92
Z-Ligustilide CRS, V-A181
Zoledronic Acid Monohydrate, II-1343
Zolmitriptan, II-1345
Zolpidem Tablets, III-1519
Zolpidem Tartrate, II-1347
Zopiclone, 151, II-1349
Zopiclone Tablets, III-1520
Zuclopenthixol Acetate, 152, II-1350
Zuclopenthixol Acetate Injection, III-1522
Zuclopenthixol Decanoate, II-1352
Zuclopenthixol Decanoate Injection, III-1523
Zuclopenthixol Hydrochloride, 152, II-1353
Zuclopenthixol Tablets, III-1524
