All suitable sample preparation methods and measurement techniques (e.g. *2.2.22. Atomic emission spectrometry* (AES), *2.2.23. Atomic absorption spectrometry* (AAS), *2.2.37. X-ray fluorescence spectrometry* (XRFS), *2.2.57. Inductively coupled plasma-atomic emission spectrometry* (ICP-AES), *2.2.58. Inductively coupled plasma-mass spectrometry* (ICP-MS), *2.4.2. Arsenic, 2.4.8. Heavy metals, 2.4.9. Iron, 2.4.10. Lead in sugars, 2.4.15. Nickel in polyols, 2.4.31. Nickel in hydrogenated vegetable oils*) can be used for the determination of elemental impurities, if the method has been verified before the initial use by a system suitability test or a validation procedure according to this chapter.

If no sample preparation and/or measurement method is described in the individual monograph, a suitable sample preparation and/or measurement method must be developed and validated (see Figures 2.4.20.-1 and 2.4.20.-2).

SAMPLE PREPARATION

Sample preparation is critical to the success of elemental analysis. Many techniques not using direct measurement are heavily dependent on sample transport.

If an atomisation system is used, the most conventional means by which samples are introduced into the atomisation system is by solution nebulisation. In this case, solid samples must be dissolved in order to be introduced into the atomisation system. Samples may be dissolved in any appropriate solvent. The use of aqueous or dilute nitric acid solutions is strongly recommended, due to minimal interference with these solvents compared to other solvents. Hydrochloric acid, hydrofluoric acid, perchloric acid, sulfuric acid and hydrogen peroxide, at various concentrations, can be used to dissolve the samples. The viscosity of sulfuric acid is greater than that of the other acids and is to be taken into account as it can affect the overall fluidity of the solution.

The choice of solvents also includes, but is not limited to, the use of dilute bases, straight or diluted organic solvents, combinations of acids or bases, and combinations of organic solvents.

Acids, bases, and hydrogen peroxide of high purity must be used, especially when ICP-MS is employed. For aqueous solutions, use *deionised distilled water R*. Diluents must be checked for interference if they are used in an analysis. Because it is not always possible to obtain organic solvents that are free from elemental impurities, organic solvents of the highest purity possible with regard to these contaminants must be used. Specifically for ICP techniques, where samples are introduced into the plasma via solution nebulisation, it is important to consider the potential matrix effects and interferences that might arise from the solvent. The use of an appropriate internal standard and/or matching the standard matrix with samples should be applied for ICP-AES and ICP-MS analyses in cases where accuracy and precision are not sufficient. In any case, the selection of an appropriate internal standard should take into account the element(s) of interest, ionisation energy, wavelengths or masses, and the nature of the sample matrix.

Where a sample is found not to be soluble in any acceptable solvent, a variety of digestion or incineration techniques can be employed. These include hot-plate digestion, incineration and microwave-assisted digestions, using an open- or closed-vessel.

The decision regarding the type of digestion technique to be used depends on the nature of the sample being digested, as well as on the element(s) of interest and the concentration range of the elements to be quantified. Open-vessel digestion is not recommended for the analysis of volatile elements. The suitability of a digestion technique, whether open- or closed-vessel, should be supported by spike recovery experiments in order to verify that, within an acceptable tolerance, volatile elements have not been lost during sample preparation. The digestion cycle is suitable if a clear solution is obtained.

It is important to consider the selection of the type, the material of construction, the pretreatment, and the cleaning of analytical labware used in elemental analyses. The material must be inert and, depending on the specific application, resistant to caustics, acids, and/or organic solvents. For some analyses, care must be exercised to prevent the adsorption of elemental impurities onto the surface of a vessel, particularly in ultra-trace analyses. Contamination of sample solutions by elemental impurities and ions present in the container can also lead to inaccurate results.

The use of volumetric glassware that does not comply with Class A requirements of the appropriate International Standard of the International Organization for Standardization (ISO) is acceptable if the validation or the system suitability test of the method using such glassware

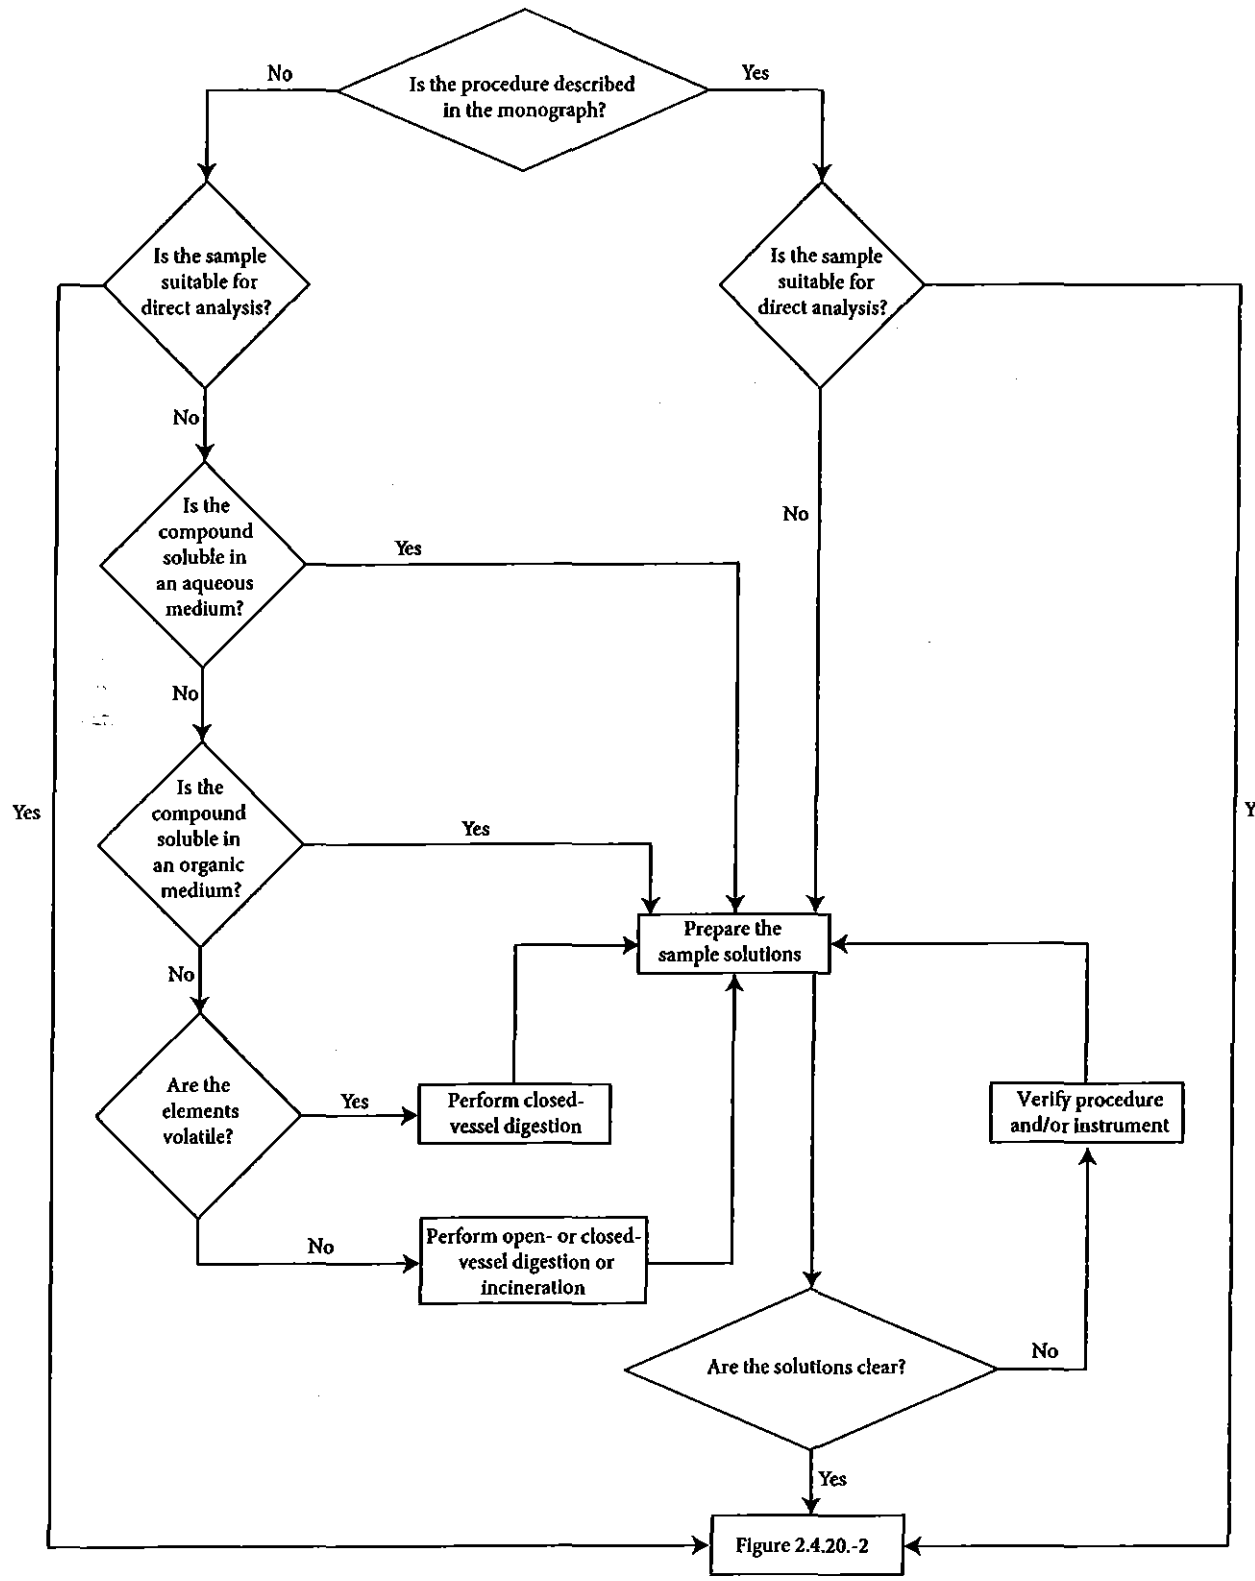

Figure 2.4.20.-1. – *Elemental impurities decision tree: sample preparation*

have experimentally demonstrated that the method is suitable for the intended purpose.

CAUTION: when using high-pressure digestion vessels and microwave laboratory equipment, the safety precautions and operating instructions given by the manufacturer must be followed.

MEASUREMENT

Method

The choice of the techniques depends mainly on the sample matrix and the characteristics and specification limits of the element(s) of interest. Analyse according to the instructions of the manufacturer of the equipment regarding program and wavelength.

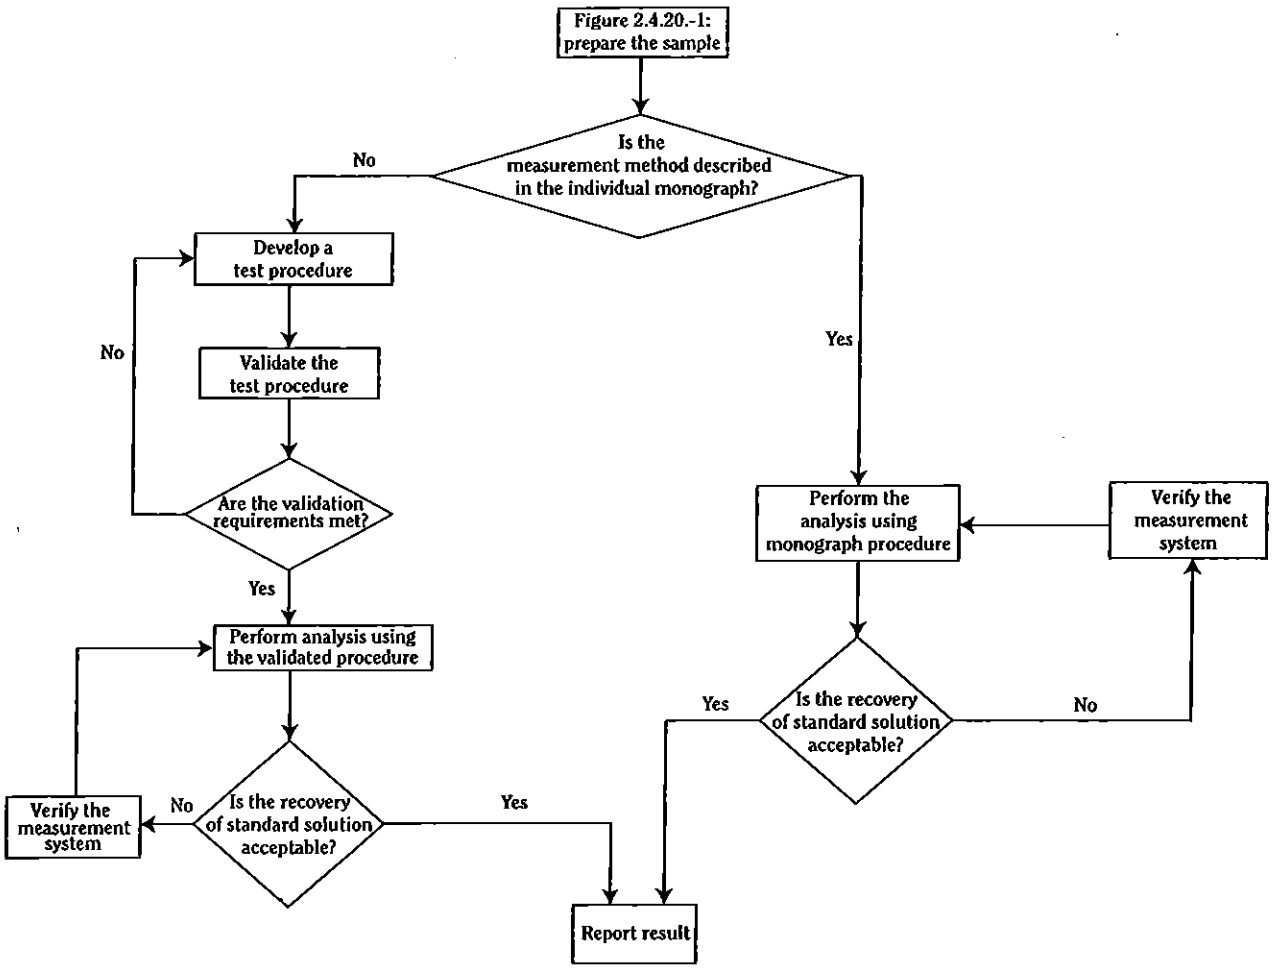

Figure 2.4.20.-2. – *Elemental impurities decision tree: measurement*

System suitability

A system suitability test must be carried out on the day of the analysis to ensure that the sample preparation and measurement system are appropriate.

Acceptance criterion for preparation of sample solution A clear solution is obtained.

Acceptance criterion for measurement system The measured concentration of a standard solution of the element at a concentration within the range of the used calibration curve does not differ from the actual concentration by more than 20 per cent.

Calculation

The blank value of reagents must be taken into account for the calculation of the content. Upon completion of the analysis, the concentration of a given element in the sample is calculated by the software of the instrument from the concentration of the element in the test solution. If no calculation software is available or no indication for calculation is given in the general chapter corresponding to the method used, the concentration of a given element in the sample can be calculated from the concentration of the element in the solution using the following expression:

$$C = A \times \frac{V_1}{m} \times \frac{V_2}{V_3}$$

C = concentration of element in the analysed sample, in micrograms per gram;

A = instrument reading of the concentration of the element in the sample solution, in micrograms per millilitre;

m = mass of the sample in the initial sample solution, in grams;

V_1 = volume of the initial sample preparation, in millilitres;

V_2 = total volume of any dilution performed, in millilitres;

V_3 = volume of initial sample preparation used in any dilution performed, in millilitres.

VALIDATION REQUIREMENTS

Some validation requirements provided below may differ from those provided in general chapters of the Ph. Eur. (e.g. *2.2.22* (AES), *2.2.23* (AAS), *2.2.57* (ICP-AES), *2.2.58* (ICP-MS)).

Before the initial use of the selected procedure, the analyst must ensure that the sample preparation and measurement method are appropriate for the element(s) of interest, sample matrix and instrument used. This is accomplished by following the validation procedure before the initial use and the system suitability test on the day of the analysis.

For elemental impurities, validation of a limit test must include specificity and limit of detection.

The following section defines the characteristics for the acceptability of a quantitative procedure. It must be demonstrated experimentally that such a procedure complies with the validation requirements, with an appropriate system suitability test using material spiked with a suitable reference material. The test materials must be spiked before any sample preparation steps. For example, if a test material is to be digested, the material must be spiked at the beginning of the digestion procedure.

SPECIFICITY

Specificity is the ability to ensure that the analytical procedure (sample preparation and measurement) allows a reliable determination of the element(s) of interest in the presence of components (e.g. carrier gas, impurities, matrix) that may be expected to be present.

Acceptance criteria The procedure must be able to assess unequivocally each elemental impurity to be determined with this procedure in the presence of components that may be expected to be present, including other elemental impurities, matrix components and other sources of interference; specificity is demonstrated by complying with the accuracy requirement for the element(s) to be determined.

RANGE

Acceptance criterion Range is demonstrated by complying with the recovery requirement.

ACCURACY

Verify the accuracy using a certified reference material or by performing a test for recovery. *Elemental impurity solutions CRS* may be used.

The recovery may be determined on a sample of the substance to be examined, spiked with a known quantity of a reference standard of the element of interest (3 concentration levels in the range of 50-150 per cent of the intended specification limit, even if the original concentration of the reference standard is at the specified value), in triplicate.

Acceptance criterion Spike recovery is within 70 per cent and 150 per cent for the mean of 3 replicates at each concentration.

REPEATABILITY

Test samples Either 6 independent samples of the substance to be examined spiked with a suitable reference standard at the specified concentration level, or 3 concentration levels prepared in triplicate.

Acceptance criterion The relative standard deviation is in both cases not more than 20 per cent.

INTERMEDIATE PRECISION

The effect of random events (intra-laboratory variations) on the analytical precision of the method must be established. Acceptable experiments for establishing intermediate precision include performing the repeatability analysis on different days, or with different instrumentation, or by different analysts. Only 1 of the 3 experiments is required to demonstrate intermediate precision.

Acceptance criterion The relative standard deviation is not more than 25 per cent.

LIMIT OF QUANTIFICATION

Use the results from the accuracy study. Determine the lowest concentration meeting the acceptance criterion.

Acceptance criterion The limit of quantification is below the specification limit.

LIMIT OF DETECTION (ONLY APPLICABLE TO LIMIT TESTS)

Determine the lowest concentration giving a signal clearly distinct from that obtained with a blank solution.

Acceptance criterion The limit of detection is not more than 0.5 times the concentration of the specification limit.

X. Methyl, Ethyl and Isopropyl Toluenesulfonate in Active Substances

(Ph. Eur. method 2.5.40)

The following general method has been validated for the determination of methyl, ethyl and isopropyl esters of toluenesulfonic acid (in concentrations between 0.2 ppm and 5 ppm) in sultamicillin tosilate dihydrate.

If it is intended to use the method for other active substances, particularly those that contain different concentrations of the toluenesulfonic acid esters, the concentrations of the test solution and reference solutions must be adjusted accordingly and the method must be suitably validated.

METHOD

Head-space gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*). *Prepare the test solution and reference solutions immediately before use.*

Solvent mixture *water R, acetonitrile R* (20:80 *V/V*). *The use of acetonitrile of appropriate purity is essential.*

Solution A Dissolve 30 mg of *anhydrous sodium thiosulfate R* and 60.0 g of *sodium iodide R* in *water R* using sonication and dilute to 50.0 mL with the same solvent.

Internal standard solution Dilute 10 µL of *butyl methanesulfonate CRS* (BMS) to 10.0 mL with the solvent mixture. Dilute 20 µL of the solution to 100.0 mL with the solvent mixture.

Blank solution Introduce 0.5 mL of solution A and 0.5 mL of the internal standard solution into a headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Test solution Weigh 25.0 mg of the substance to be examined into a 20 mL headspace vial. Add 0.50 mL of solution A and 0.50 mL of the internal standard solution and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Following the derivatisation reaction, a precipitate may be observed, however this does not affect the validity of the quantification.

Reference solution (a) Dissolve 25.0 mg each of *methyl toluenesulfonate R* (MTS), *ethyl toluenesulfonate R* (ETS) and *isopropyl toluenesulfonate R* (ITS) in *toluene R* and dilute to 5.0 mL with the same solvent. Dilute 50 µL of the solution to 25.0 mL with the internal standard solution.

Reference solution (b) Dilute 40 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Reference solution (c) Dilute 500 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Column:

— *material*: fused silica;
— *size*: *l* = 30 m, Ø = 0.25 mm;
— *stationary phase*: *polar-deactivated macrogol R* (film thickness 1 µm).

Carrier gas *helium for chromatography R.*

The use of an inert inlet liner without glass wool significantly reduces the effect of carry-over between the injections.

Flow rate 0.5 mL/min.

Split ratio 1:20.

Static head-space conditions that may be used:
— *equilibration temperature*: 60 °C;
— *equilibration time*: 30 min;
— *transfer-line temperature*: 120 °C.

Temperature:

		Time (min)	Temperature (°C)
Column		0 - 1	40
		1 - 10	40 → 130
Injection port			220
Detector	transfer line		280
	source		250
	analyser		200

At the end of analysis the temperature of the column is raised to 240 °C and maintained at this temperature for 7 min.

Detection Mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:
— quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
— mass spectrometer parameters for the fragmentometric mode (single-ion monitoring (SIM)) set as follows:

Substance	Quantitation Ion (m/z)	Qualification Ion (m/z)
Butyl iodide (BuI)*	184	127
Methyl iodide (MeI)*	142	127
Ethyl iodide (EtI)*	156	127
Isopropyl iodide (iPrI)*	170	127
* formed from BMS, MTS, ETS and ITS in the derivatisation reaction.		

Injection 1 mL of the gas phase of the test solution, reference solutions (b) and (c) and of the blank solution.

Relative retention With reference to the internal standard (BuI) (retention time = about 8.5 min): MeI = about 0.51; EtI = about 0.63; iPrI = about 0.68.

System suitability:
— *resolution*: minimum 1.5 between the peaks due to EtI and iPrI in the chromatogram obtained with reference solution (c);
— *signal-to-noise ratio*: minimum 10 for the peak due to each alkyl iodide in the chromatogram obtained with reference solution (b).

Calculate the content in parts per million of each alkyl toluenesulfonate using the following expression:

$$\frac{A_2 \times I_1 \times W_1 \times C \times 0.05}{A_1 \times I_2 \times W_2}$$

A_1 = area of the peak due to each alkyl iodide in the chromatogram obtained with reference solution (c);
A_2 = area of the peak due to each alkyl iodide in the chromatogram obtained with the test solution;
C = percentage content of each ester;
I_1 = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c);
I_2 = area of the peak due to the internal standard in the chromatogram obtained with the test solution;
W_1 = mass of each ester used to prepare reference solution (a), in milligrams;
W_2 = mass of the substance to be examined in the test solution, in milligrams;
0.05 = dilution factor.

Y. Methyl, Ethyl and Isopropyl Benzenesulfonate in Active Substances

(Ph. Eur. method 2.5.41)

The following general method has been validated for the determination of methyl, ethyl and isopropyl esters of benzenesulfonic acid (in concentrations between 2.5 ppm and 40 ppm) in amlodipine besilate.

If it is intended to use the method for other active substances, particularly those that contain different concentrations of the benzenesulfonic acid esters, the concentrations of the test solution and reference solutions must be adjusted accordingly and the method must be suitably validated.

This method is not suitable for clopidogrel besilate as it was observed that methyl benzenesulfonate was obtained during the gas chromatographic analysis as an artefact originating from degradation.

METHOD

Head-space gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*). *Prepare the test solution and reference solutions immediately before use.*

Solvent mixture *water R, acetonitrile R* (20:80 *V/V*). *The use of acetonitrile of appropriate purity is essential.*

Solution A Dissolve with the aid of ultrasound 30 mg of *anhydrous sodium thiosulfate R* and 60.0 g of *sodium iodide R* in *water R* and dilute to 50.0 mL with the same solvent.

Internal standard solution Dilute 10 µL of *butyl methanesulfonate CRS* (BMS) to 10.0 mL with the solvent mixture. Dilute 20 µL of the solution to 100.0 mL with the solvent mixture.

Blank solution Introduce 0.50 mL of solution A and 0.50 mL of the internal standard solution into a headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Test solution Weigh 25.0 mg of the substance to be examined into a 20 mL headspace vial. Add 0.50 mL of solution A and 0.50 mL of the internal standard solution and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Following the derivatisation reaction, a precipitate may be observed, however this does not affect the validity of the quantification.

Reference solution (a) Dissolve 25.0 mg each of *methyl benzenesulfonate R* (MBS), *ethyl benzenesulfonate R* (EBS) and *isopropyl methanesulfonate R* (IMS) in *toluene R* and dilute to 5.0 mL with the same solvent. Dilute 50 µL of the solution to 25.0 mL with the internal standard solution.

Reference solution (b) Dilute 40 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Reference solution (c) Dilute 500 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

Column:
— *material*: fused silica;
— *size*: *l* = 30 m, Ø = 0.25 mm;
— *stationary phase*: *polar-deactivated macrogol R* (film thickness 1 µm).

Carrier gas *helium for chromatography R.*

The use of an inert inlet liner without glass wool significantly reduces the effect of carry-over between the injections.

Flow rate 0.5 mL/min.

Split ratio 1:20.

Static head-space conditions that may be used:
— *equilibration temperature*: 60 °C;
— *equilibration time*: 30 min;
— *transfer-line temperature*: 120 °C.

Temperature:

		Time (min)	Temperature (°C)
Column		0 - 1	40
		1 - 10	40 → 130
Injection port			220
Detector	transfer line		280
	source		250
	analyser		200

At the end of analysis, the temperature of the column is raised to 240 °C and maintained at this temperature for 7 min.

Detection Mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:
— quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
— mass spectrometer parameters for the fragmentometric mode (single-ion monitoring (SIM)) set as follows:

Substance	Quantitation ion (*m/z*)	Qualification ion (*m/z*)
Butyl iodide (BuI)*	184	127
Methyl iodide (MeI)*	142	127
Ethyl iodide (EtI)*	156	127
Isopropyl iodide (iPrI)*	170	127
* formed from BMS, MBS, EBS and IMS in the derivatisation reaction.		

Injection 1 mL of the gas phase of the test solution, reference solutions (b) and (c) and the blank solution.

Relative retention With reference to the internal standard (BuI) (retention time = about 8.5 min): MeI = about 0.51; EtI = about 0.63; iPrI = about 0.68.

System suitability:
— *resolution*: minimum 1.5 between the peaks due to EtI and iPrI in the chromatogram obtained with reference solution (c);
— *signal-to-noise ratio*: minimum 10 for the peak due to each alkyl iodide in the chromatogram obtained with reference solution (b).

Calculate the content in parts per million of each alkyl benzenesulfonate using the following expression:

$$\frac{A_2 \times I_1 \times W_1 \times C \times 0.05}{A_1 \times I_2 \times W_2}$$

A_1 = area of the peak due to each alkyl iodide in the chromatogram obtained with reference solution (c);
A_2 = area of the peak due to each alkyl iodide in the chromatogram obtained with the test solution;
C = percentage content of each ester;
I_1 = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c);
I_2 = area of the peak due to the internal standard in the chromatogram obtained with the test solution;
W_1 = mass of each ester used to prepare reference solution (a), in milligrams;
W_2 = mass of the substance to be examined in the test solution, in milligrams;
0.05 = dilution factor.

Z. Tetrabutylammonium in Radiopharmaceutical Preparations

(Ph. Eur. method 2.4.33 Tetrabutylammonium in Radiopharmaceutical Preparations)

Thin-layer chromatography (*2.2.27*).

Solvent mixture *anhydrous ethanol R, water R* (10:90 *V/V*).

Test solution The preparation to be examined.

Reference solution Dissolve 0.86 g of *tetrabutylammonium hydroxide R* in the solvent mixture and dilute to 100 mL with the solvent mixture. Dilute 1 mL of the solution to *V* with the solvent mixture, *V* being the maximum recommended dose in millilitres.

Plate *TLC silica gel plate R*; use a polyester plate.

Mobile phase:
— *mobile phase A*: *concentrated ammonia R, methanol R* (10:90 *V/V*);
— *mobile phase B*: *concentrated ammonia R, methanol R* (0.5:100 *V/V*).

Use either mobile phase A or mobile phase B. The choice of mobile phase depends on the matrix (for example, mobile phase B is suitable for preparations stabilised with ascorbate). Spiking experiments can be done to verify the suitability of the mobile phase and to show that the sample matrix has no influence on the results.

Application 2 µL.

Development Over 4/5 of the plate.

Drying At 50 °C for maximum 30 s.

Detection Place 0.5 g of *iodine R* at the bottom of a chromatographic tank; close the tank and heat it with a stream of hot air (about 60-80 °C) until it is filled with pink vapour; place the plate in the tank; leave the plate in contact with the iodine vapour for 1 min; withdraw the plate.

System suitability:
— the chromatogram obtained with the reference solution shows a clearly visible spot.

Limit:
— *tetrabutylammonium*: any spot due to tetrabutylammonium is not more intense than the corresponding spot in the chromatogram obtained with the reference solution (2.6mg/V).

Appendix IX

A. Determination of Sulfated Ash

Use Method I unless otherwise directed.

Method I

(No Ph. Eur. method)

Heat a platinum dish to redness for 10 minutes, allow to cool in a desiccator and weigh. Unless otherwise specified in the monograph, place 1 g of the substance being examined in the dish, moisten with *sulfuric acid*, ignite gently, again moisten with *sulfuric acid* and ignite at about 800°. Cool, weigh again, ignite for 15 minutes and repeat this procedure until two successive weighings do not differ by more than 0.5 mg.

Method II[1]

(Ph. Eur. method 2.4.14)

Ignite a suitable crucible (for example, silica, platinum, porcelain or quartz) at 600 ± 50 °C for 30 min, allow to cool in a desiccator over silica gel or other suitable desiccant and weigh. Place the prescribed amount of the substance to be examined in the crucible and weigh. Moisten the substance to be examined with a small amount of *sulfuric acid R* (usually 1 mL) and heat gently at as low a temperature as practicable until the sample is thoroughly charred. After cooling, moisten the residue with a small amount of *sulfuric acid R* (usually 1 mL), heat gently until white fumes are no longer evolved and ignite at 600 ± 50 °C until the residue is completely incinerated. Ensure that flames are not produced at any time during the procedure. Allow the crucible to cool in a desiccator over silica gel or other suitable desiccant, weigh it again and calculate the percentage of residue.

If the amount of the residue so obtained exceeds the prescribed limit, repeat the moistening with *sulfuric acid R* and ignition, as previously, for 30 min periods until 2 consecutive weighings do not differ by more than 0.5 mg or until the percentage of residue complies with the prescribed limit.

The amount of substance used for the test (usually 1-2 g) is chosen so that at the prescribed limit the mass of the residue (usually about 1 mg) can be measured with sufficient accuracy.

B. Determination of Sulfur Dioxide

Method I

(No Ph. Eur. method)

Apparatus A round-bottomed flask of 1000- to 1500-mL capacity is fitted with a water-cooled reflux condenser the upper end of which is connected to two absorption tubes in series. The flask is fitted with a gas inlet tube which reaches nearly to the bottom of the flask. Each absorption tube contains 10 mL of *hydrogen peroxide solution (20 vol)* previously neutralised with 0.1M *sodium hydroxide VS* using *bromophenol blue solution* as indicator.

Method Place in the flask 500 mL of *water* and 20 mL of *hydrochloric acid*. Pass through the flask a steady current of *nitrogen* or *carbon dioxide* that has been bubbled through *dilute sodium carbonate solution* and gradually heat the liquid until it boils. Maintain the current of *nitrogen* or *carbon dioxide*, allow the solution to boil for about 10 minutes and cool the flask by gradual immersion in water. Introduce, while momentarily removing the stopper of the flask, a weighed quantity of 50 to 100 g of the substance being examined, heat gently and boil for 45 minutes. Disconnect the absorption tubes before turning off the current of *nitrogen* or *carbon dioxide* and titrate the combined contents with 0.1M *sodium hydroxide VS*. Each mL of 0.1M *sodium hydroxide VS* is equivalent to 3.203 mg of sulfur dioxide.

Repeat the operation without the substance being examined. The solution in the absorption tubes remains neutral.

Method II

(Ph. Eur. method 2.5.29)

EQUIPMENT

The apparatus as shown in Figure 2.5.29.-1 comprises:
— a ground-glass 3-neck round-bottomed flask (*A*);
— a dropping funnel (*B*);
— a reflux condenser (*C*);
— a receiving tube (*D*);
— a transfer tube (*E*);
— a gas port.

PROCEDURE

Method

Introduce 150 mL of *water R* into the flask (*A*) and equilibrate the whole system by passing *carbon dioxide R* for 15 min at a rate of about 100 mL/min.

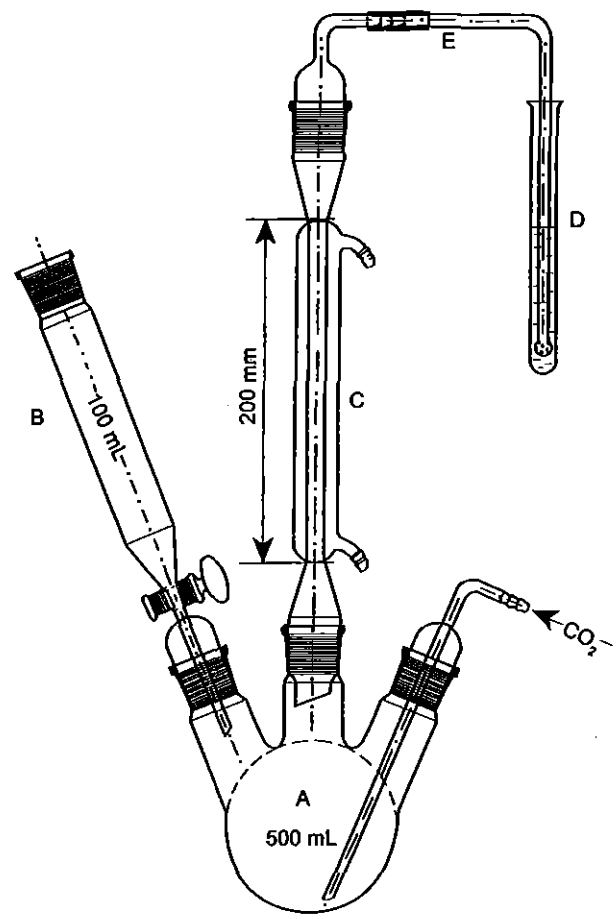

Figure 2.5.29.-1.– *Apparatus for the determination of sulfur dioxide content*

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

To 10 mL of *dilute hydrogen peroxide solution R*, add 0.15 mL of a 1 g/L solution of *bromophenol blue R* in *ethanol (20 per cent V/V) R*. Add *0.1 M sodium hydroxide* until a violet-blue colour is obtained, without exceeding the end-point. Pour the solution into the receiving tube (*D*) and mount the tube on the apparatus as shown in Figure 2.5.29.-1.

Without interrupting the stream of carbon dioxide, remove the dropping funnel (*B*) and introduce into the flask (*A*) 25.0 g (*m*) of the substance to be examined, rinsing with 100 mL of *water R*. Replace the dropping funnel, close the tap and pour 80 mL of *dilute hydrochloric acid R* into the funnel. Open the tap to allow the hydrochloric acid solution to flow into the flask. Make sure that no sulfur dioxide escapes by closing the tap before the last few millilitres of hydrochloric acid solution drain out. Boil for 1 h.

Open the tap of the dropping funnel then stop the flow of carbon dioxide . Transfer the contents of the receivingtube (*D*) to a 200 mL conical flask, rinsing the tube with a little *water R*. Heat on a water-bath for 15 min and allow to cool. Add 0.1 mL of a 1 g/L solution of *bromophenol blue R* in *ethanol (20 per cent V/V) R* and titrate with *0.1 M sodium hydroxide* until the colour changes from yellow to violet-blue (V_1). Carry out a blank titration (V_2).

Results

Calculate the content of sulfur dioxide, in parts per million, using the following expression:

$$32\,030 \times (V_1 - V_2) \times \frac{n}{m}$$

V_1 = volume of titrant used in the titration, in millilitres;
V_2 = volume of titrant used in the blank titration, in millilitres;
n = molarity of the sodium hydroxide solution used as titrant, in moles per litre;
m = mass of the sample, in grams.

C. Determination of Water

Use Method IA unless otherwise directed.

Method I Semi-micro Determination of Water

(Ph. Eur. method 2.5.12)

The semi-micro determination of water is based upon the quantitative reaction of water with sulfur dioxide and iodine in a suitable anhydrous medium in the presence of a base with sufficient buffering capacity.

APPARATUS

The apparatus consists of a titration vessel with:
— 2 identical platinum electrodes;
— tight inlets for introduction of solvent and titrant;
— an inlet for introduction of air via a desiccant;
— a sample inlet fitted with a stopper or, for liquids, a septum.

Inlet systems for introduction of dry nitrogen or for aspiration of solvents may also be fitted.

The titration is carried out according to the instrument supplier's instructions. Care is taken throughout the determination to avoid exposure of reagents and solvents to atmospheric moisture. The end-point is determined using 2 identical indicator electrodes connected to an electrical source that maintains between the electrodes either a constant current (*2.2.65. Voltametric titration*) or a constant voltage (*2.2.19. Amperometric titration*). Where direct titration is used (method A), addition of titrant causes either a decrease in voltage where constant current is maintained or an increase in current where constant voltage is maintained, until the end-point is reached. Instruments with automatic end-point detection are commonly used. Instrument qualification is carried out according to established quality system procedures, for example using a suitable certified reference material (*sodium aminosalicylate dihydrate for equipment qualification CRS* may be used).

STANDARDISATION

To the titration vessel, add *methanol R*, dried if necessary, or the solvent recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce a suitable amount of water in an appropriate form (*water R* or a certified reference material) and carry out the titration, stirring for the necessary time. The water equivalent is not less than 80 per cent of that indicated by the supplier. Standardise the titrant before the first use and at suitable intervals thereafter.

Unless otherwise prescribed, use Method A.

METHOD A

Introduce into the titration vessel *methanol R*, or the solvent indicated in the monograph or recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce the substance to be examined rapidly and carry out the titration, stirring for the necessary extraction time.

METHOD B

Introduce into the titration vessel *methanol R*, or the solvent indicated in the monograph or recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce the substance to be examined rapidly and in a suitable state of division. Add an accurately measured volume of the titrant, sufficient to give an excess of about 1 mL or the prescribed volume. Allow to stand protected from light for 1 min or the prescribed time, with stirring. Titrate the excess of reagent using *methanol R* or the prescribed solvent, containing an accurately known quantity of water.

SUITABILITY

The accuracy of the determination with the chosen titrant must be verified for each combination of substance, titrant and solvent to be examined. The following procedure, given as an example, is suitable for samples containing 2.5-25 mg of water.

The water content of the substance to be examined is determined using the reagent/solvent system chosen. Thereafter, in the same titration vessel, sequential known amounts of water, corresponding to about 50-100 per cent of the amount found in the substance to be examined, are added in an appropriate form (at least 5 additions) and the water content is determined after each addition. Calculate the percentage recovery (r) after each addition using the following expression:

$$r = 100\frac{W_2}{W_1}$$

W_1 = amount of water added, in milligrams;
W_2 = amount of water found, in milligrams.

Calculate the mean percentage recovery ($\bar{r}$).
The reagent/solvent system is considered to be acceptable if $\bar{r}$ is between 97.5 per cent and 102.5 per cent.

Calculate the regression line. The x-axis represents the cumulative water added whereas the y-axis represents the sum of the initial water content determined for the substance (M) and the cumulative water determined after each addition. Calculate the slope (b), the intercept with the y-axis (a) and the intercept of the extrapolated calibration line with the x-axis (d).

Calculate the percentage errors (e_1 and e_2) using the following expressions:

$$e_1 = 100\frac{a - M}{M}$$

$$e_2 = 100\frac{|d| - M}{M}$$

a = the y-axis intercept, in milligrams of water;
d = the x-axis intercept, in milligrams of water;
M = water content of the substance, in milligrams of water.

The reagent/solvent system is considered to be acceptable if:
— $|e_1|$ and $|e_2|$ are not greater than 2.5 per cent;
— b is between 0.975 and 1.025.

Method II Determination of Water by Distillation
(Ph. Eur. method 2.2.13)

The apparatus (see Figure 2.2.13.-1) consists of a glass flask (*A*) connected by a tube (*D*) to a cylindrical tube (*B*) fitted with a graduated receiving tube (*E*) and reflux condenser (*C*). The receiving tube (*E*) is graduated in 0.1 mL. The source of heat is preferably an electric heater with rheostat control or an oil bath. The upper portion of the flask and the connecting tube may be insulated.

Method Clean the receiving tube and the condenser of the apparatus, thoroughly rinse with water, and dry.

Introduce 200 mL of *toluene R* and about 2 mL of *water R* into the dry flask. Distil for 2 h, then allow to cool for about 30 min and read the water volume to the nearest 0.05 mL. Place in the flask a quantity of the substance, weighed with an accuracy of 1 per cent, expected to give about 2 mL to 3 mL of water. If the substance has a pasty consistency, weigh it in a boat of metal foil. Add a few pieces of porous material and heat the flask gently for 15 min. When the toluene begins to boil, distil at the rate of about two drops per second until most of the water has distilled over, then increase the rate of distillation to about four drops per second. When the water has all distilled over, rinse the inside of the condenser tube with *toluene R*. Continue the distillation for 5 min, remove the heat, allow the receiving tube to cool to room temperature and dislodge any droplets of water which adhere to the walls of the receiving tube. When the water and toluene have completely separated, read the volume of water and calculate the content present in the substance as millilitres per kilogram, using the formula:

$$\frac{1000(n_2 - n_1)}{m}$$

m = the mass in grams of the substance to be examined,
n_1 = the number of millilitres of water obtained in the first distillation,
n_2 = the total number of millilitres of water obtained in the 2 distillations.

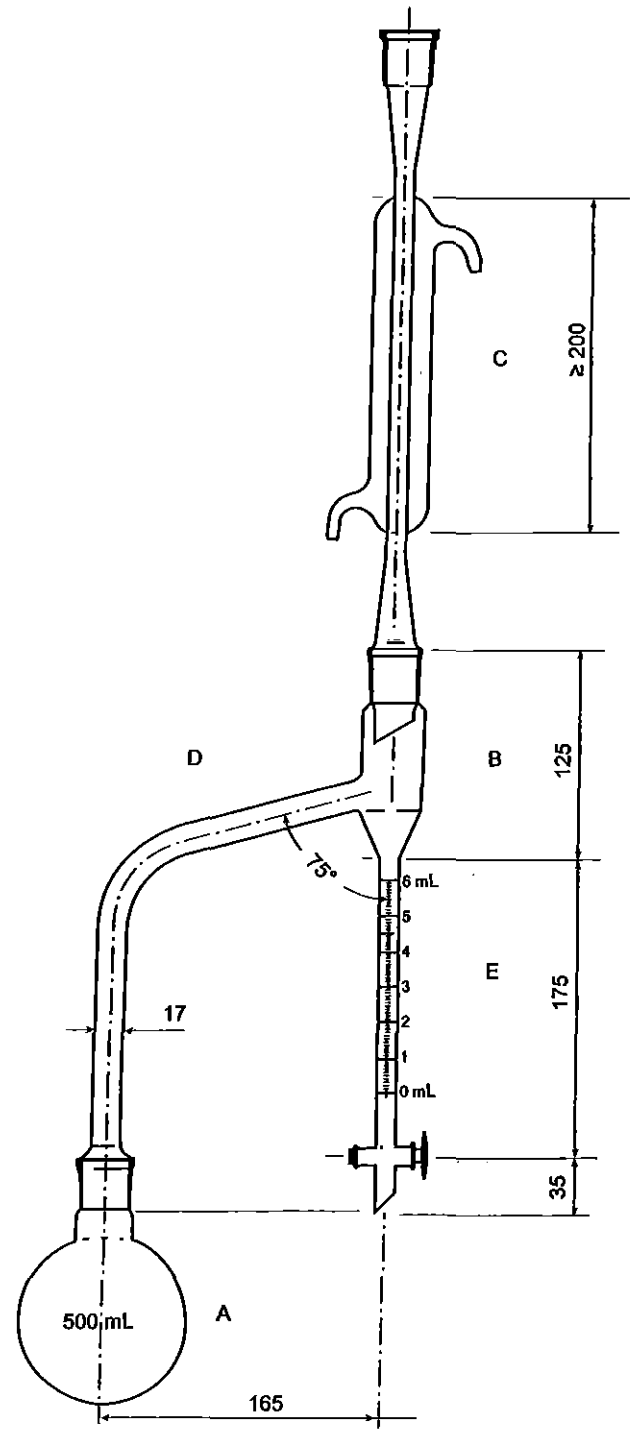

Figure 2.2.13.-1. – *Apparatus for the determination of water by distillation*
Dimensions in millimetres

Method III Coulometric Titration
(Ph. Eur. method 2.5.32)

PRINCIPLE

The coulometric titration of water is based upon the quantitative reaction of water with sulfur dioxide and iodine in an anhydrous medium in the presence of a base with sufficient buffering capacity. In contrast to the volumetric method described in general chapter *2.5.12. Water: semi-micro determination*, iodine is produced electrochemically in the reaction cell by oxidation of iodide. The iodine produced at

the anode reacts immediately with the water and the sulfur dioxide contained in the reaction cell. The quantity of water in the substance is directly proportional to the quantity of electricity (in coulombs), corresponding to electric current (in amperes) multiplied by time (in seconds), used for iodine generation up until the titration end-point. When all of the water in the reaction cell has been consumed, the end-point is reached and thus an excess of iodine appears. 1 mole of iodine corresponds to 1 mole of water, an amount of electricity of 10.71 C corresponds to 1 mg of water.

Moisture is eliminated from the reaction cell by pre-titration, i.e. the electrolyte reagent is titrated to dryness before starting the sample analysis. Individual determinations can be carried out successively in the same reagent solution, under the following conditions:

— each component of the test mixture is compatible with the other components;
— no other reactions take place;
— the volume and the water capacity of the electrolyte reagent are sufficient.

Coulometric titration is intended for the quantitative determination of small quantities of water (from 10 µg), however a working range of 100 µg to 10 mg of water is recommended for reproducibility reasons.

Accuracy and precision of the method are predominantly governed by the sample preparation and the extent to which atmospheric moisture is excluded from the system. Control of the system must be monitored by measuring the amount of baseline drift.

APPARATUS

The apparatus consists of a reaction cell, electrodes and a magnetic stirrer. The reaction cell consists of a large anode compartment and a smaller cathode compartment. Depending on the design of the electrode, both compartments can be separated by a diaphragm. Each compartment contains a platinum electrode. Liquid or solubilised samples are introduced through a septum, using a syringe. Alternatively, an evaporation technique may be used in which the sample is heated in an oven and the water is evaporated and carried into the cell by means of a stream of dry inert gas. The introduction of solid samples into the cell should in general be avoided. However, if it has to be done it is effected through a sealable port; appropriate precautions must be taken to avoid the introduction of moisture from air, such as working in a glove box in an atmosphere of dry inert gas. The analytical procedure is controlled by a suitable electronic device, which also displays the results.

Instrument qualification is carried out according to established quality system procedures, for example using a suitable certified reference material. *Sodium aminosalicylate dihydrate for equipment qualification CRS* may be used when proceeding by direct or liquid sample introduction, whereas *amoxicillin trihydrate for performance verification CRS* may be used with the evaporation technique.

METHOD

Fill the compartments of the reaction cell with *electrolyte reagent for the micro determination of water R* according to the manufacturer's instructions and perform the coulometric pre-titration to a stable end-point. Introduce the prescribed quantity of the substance to be examined into the reaction cell and titrate again to a stable end-point, stirring for at least 30 s, unless otherwise indicated in the monograph. If an oven is used, the prescribed quantity of sample is introduced into the oven and heated. After evaporation of the water from the sample into the reaction cell, the titration is started.

Alternatively, the evaporated moisture is immediately titrated while heating the sample in the oven to avoid loss of evaporated water already collected in the reagent solution during prolonged heating. Read the value from the instrument's output and calculate if necessary the percentage or quantity of water that is present in the substance. When appropriate to the type of sample and the sample preparation, perform a blank titration.

VERIFICATION OF ACCURACY

At appropriate intervals, such as at least at the beginning and the end of a series of sample titrations, introduce a defined quantity of water, in the same order of magnitude as the quantity of water in the sample, using a suitable certified reference material and perform the coulometric titration. The recovery is within the range of 97.5 per cent to 102.5 per cent for an addition of 1000 µg of H_2O and within the range of 90.0 per cent to 110.0 per cent for the addition of 100 µg of H_2O.

D. Determination of Loss on Drying

(Ph. Eur. method 2.2.32)

PRINCIPLE

Loss on drying is the loss of mass after drying under specified conditions, calculated as a percentage (*m/m*).

Drying to constant mass means that 2 consecutive weighings do not differ by more than 0.5 mg, the 2nd weighing following an additional period of at least 30 min of drying under the conditions prescribed for the substance to be examined.

EQUIPMENT

The equipment typically consists of:

— weighing bottles that are made of suitable inert material and can easily be dried to constant mass; their diameter is large enough so that the layer of the substance to be examined does not exceed about 5 mm;
— an analytical balance by which it is possible to determine a change in mass of 0.1 mg;
— depending on the procedure to be applied, a desiccator, a vacuum cabinet, a vacuum oven or an ordinary laboratory oven; in any case, the temperature of ovens is adjustable to the specified temperature ± 2 °C; vacuum ovens in which the pressure can at least be reduced to about 2 kPa are suitable; ovens are qualified according to established quality system procedures, for example by using a suitable certified reference material (*sodium aminosalicylate dihydrate for equipment qualification CRS* may be used).

Equipment using other means of drying such as microwaves, halogen lamps, infrared lamps or mixed technologies may be used provided they are demonstrated to be fit for purpose.

PROCEDURE

It is recommended to perform the test in an environment that has minimal impact on sample measurement (e.g. humidity).

Weigh an empty weighing bottle that has been previously dried under the conditions prescribed for the substance to be examined for at least 30 min, then weigh the weighing bottle filled with the prescribed quantity of substance to be examined. Dry to constant mass or for the prescribed time. Where the drying temperature is indicated by a single value rather than a range, drying is carried out at the prescribed

temperature ± 2 °C. Use one of the following procedures, unless otherwise prescribed in the monograph.

— In a desiccator: the drying is carried out over about 100 g of *molecular sieve R* at atmospheric pressure and at room temperature.
— *In vacuo*: the drying is carried out over about 100 g of *molecular sieve R* at a pressure not exceeding 2.5 kPa, at room temperature or at the temperature prescribed in the monograph.
— In an oven at a specified temperature: the drying is carried out at atmospheric pressure in an oven at the temperature prescribed in the monograph.

After drying in an oven, allow the weighing bottle and the sample to cool to room temperature in a desiccator and weigh the weighing bottle containing the dried sample.

The mass of the sample is the difference between the mass of the filled weighing bottle and the mass of the dried empty weighing bottle.

The loss on drying is the difference in the mass of the sample before and after drying, expressed as a percentage, *m/m* being implicit.

E. Limit Test for Carbon Monoxide in Medicinal Gases

(Ph. Eur. method 2.5.25)

METHOD I

Apparatus The apparatus (Figure 2.5.25.-1) consists of the following parts connected in series:

— a U-tube (U_1) containing *anhydrous silica gel R* impregnated with *chromium trioxide R*;
— a wash bottle (F_1) containing 100 mL of a 400 g/L solution of *potassium hydroxide R*;
— a U-tube (U_2) containing pellets of *potassium hydroxide R*;
— a U-tube (U_3) containing *diphosphorus pentoxide R* dispersed on previously granulated, fused pumice;
— a U-tube (U_4) containing 30 g of *recrystallised iodine pentoxide R* in granules, previously dried at 200 °C and kept at a temperature of 120 °C (T) during the test; the iodine pentoxide is packed in the tube in 1 cm columns separated by 1 cm columns of glass wool to give an effective length of 5 cm;
— a reaction tube (F_2) containing 2.0 mL of *potassium iodide solution R* and 0.15 mL of *starch solution R*.

Method Flush the apparatus with 5.0 L of *argon R* and, if necessary, discharge the blue colour in the iodide solution by adding the smallest necessary quantity of freshly prepared *0.002 M sodium thiosulfate*. Continue flushing until not more than 0.045 mL of *0.002 M sodium thiosulfate* is required after passage of 5.0 L of *argon R*. Pass the gas to be examined from the cylinder through the apparatus, using the prescribed volume and the flow rate. Flush the last traces of liberated iodine into the reaction tube by passing through the apparatus 1.0 L of *argon R*. Titrate the liberated iodine with *0.002 M sodium thiosulfate*. Carry out a blank test, using the prescribed volume of *argon R*. The difference between the volumes of *0.002 M sodium thiosulfate* used in the titrations is not greater than the prescribed limit.

METHOD II

Gases absorb light at one or more specific wavelengths. This property is widely used to allow highly selective measurement of their concentrations.

Description and principle of measurement

The concentration of carbon monoxide in other gases can be determined using an infrared analyser.

The infrared analyser generally consists of a light source emitting broadband infrared radiation, an optical device, a sample cell and a detector. The optical device may be positioned either before or after the sample cell; it consists of one or several optical filters, through which the broadband radiation is passed. The optical device in this case is selected for carbon monoxide. The measurement light beam passes through the sample cell and may also pass through a reference cell if the analyser integrates such a feature (some use an electronic system instead of a reference cell).

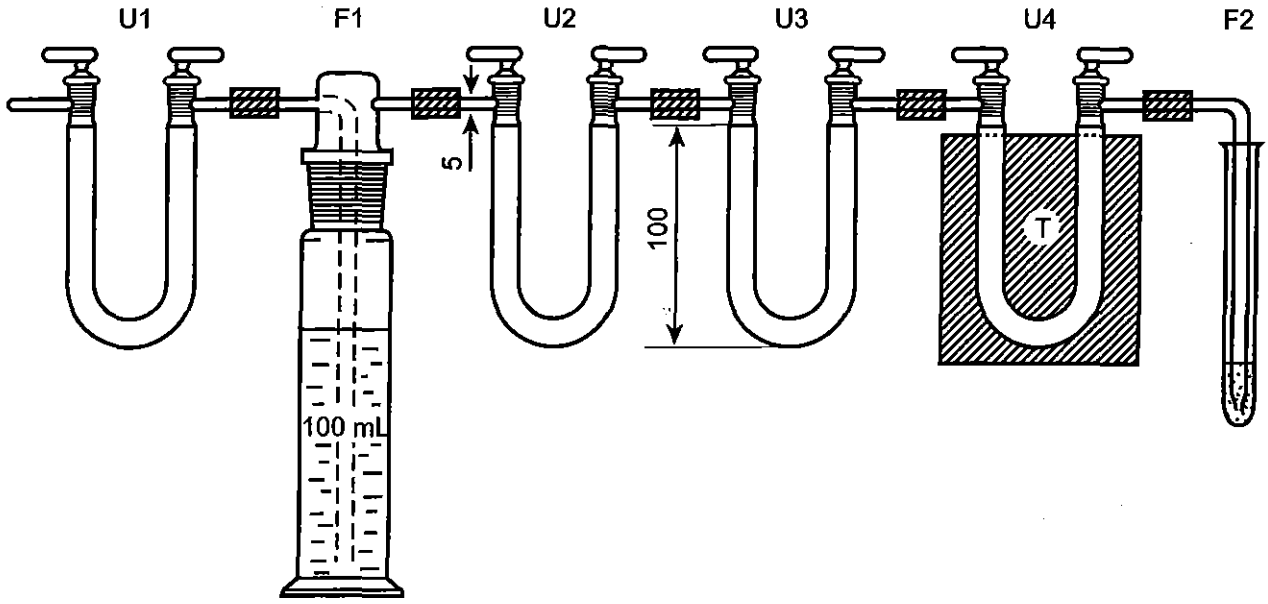

Figure 2.5.25.-1. – *Apparatus for the determination of carbon monoxide*
Dimensions in millimetres

When carbon monoxide is present in the sample cell, absorption of energy in the measurement light beam will occur according to the Beer-Lambert law and this produces a change in the detector signal. This measurement signal is compared to a reference signal to generate an output related to the concentration of carbon monoxide. The generated signal is linearised in order to obtain the carbon monoxide concentration. To prevent the entry of particles into the sensors, which could cause stray-light phenomena, the apparatus is fitted with a suitable filter.

Required technical specifications

When used for a limit test, the carbon monoxide infrared analyser meets the following technical specifications:

— *limit of detection*: (generally defined as a signal-to-noise ratio of 2) maximum 20 per cent of the maximum admissible concentration;

— *repeatability*: maximum relative standard deviation of 10 per cent of the maximum admissible concentration, determined on 6 measurements;

— *linearity*: maximum 10 per cent of the maximum admissible concentration.

The technical specifications must be met in the presence of the other gas impurities in the sample.

F. Determination of Carbon Dioxide in Medicinal Gases

(Ph. Eur. method 2.5.24)

Gases absorb light at one or more specific wavelengths. This property is widely used to allow highly selective measurement of their concentrations.

Description and principle of measurement

The concentration of carbon dioxide in other gases can be determined using an infrared analyser.

The infrared analyser generally consists of a light source emitting broadband infrared radiation, an optical device, a sample cell and a detector. The optical device may be positioned either before or after the sample cell and it consists of one or several optical filters, through which the broadband radiation is passed. The optical device in this case is selected for carbon dioxide. The measurement light beam passes through the sample cell and may also pass through a reference cell if the analyser integrates such a feature (some use an electronic system instead of a reference cell).

When carbon dioxide is present in the sample cell, absorption of energy in the measurement light beam will occur according to the Beer-Lambert law and this produces a change in the detector signal. This measurement signal is compared to a reference signal to generate an output related to the concentration of carbon dioxide. The generated signal is linearised in order to obtain the carbon dioxide concentration. To prevent the entry of particles into the sensors, which could cause stray-light phenomena, the apparatus is fitted with a suitable filter.

Required technical specifications

When used for a limit test, the infrared analyser meets the following technical specifications:

— *limit of detection*: (generally defined as a signal-to-noise ratio of 2) maximum 20 per cent of the maximum admissible concentration;

— *repeatability*: maximum relative standard deviation of 10 per cent of the maximum admissible concentration, determined on 6 measurements;

— *linearity*: maximum 10 per cent of the maximum admissible concentration.

The technical specifications must be met in the presence of the other gas impurities in the sample.

G. Determination of Nitrogen Monoxide and Nitrogen Dioxide in Medicinal Gases

(Ph. Eur. method 2.5.26)

Nitrogen monoxide and nitrogen dioxide in gases are determined using a chemiluminescence analyser (Figure 2.5.26.-1).

The apparatus consists of the following:

— a device for filtering, checking and controlling the flow of the gas to be examined,

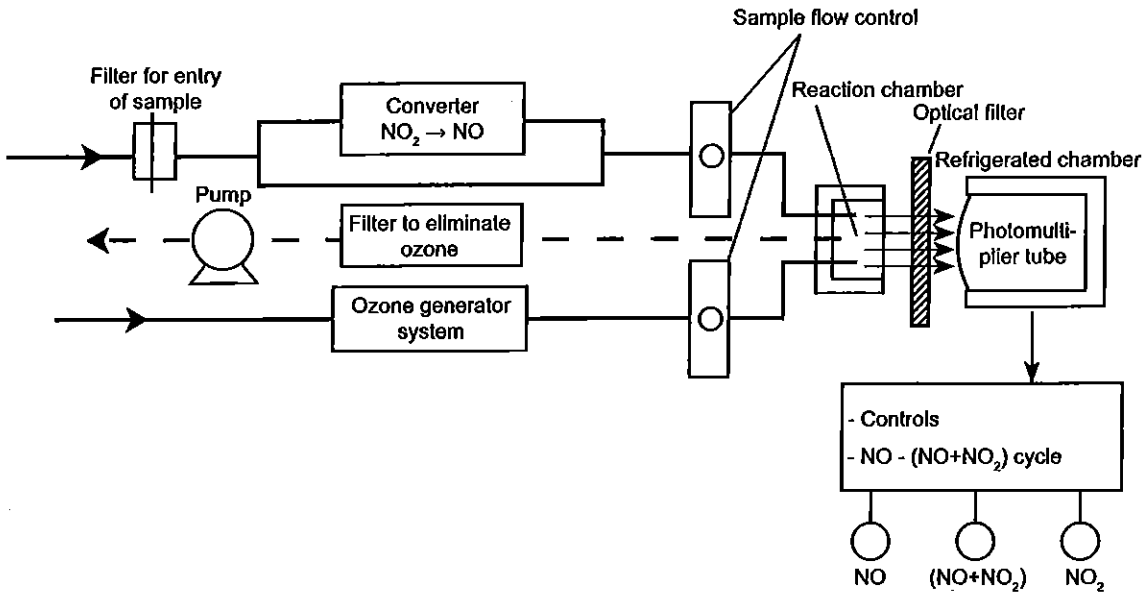

Figure 2.5.26.-1. – *Chemiluminescence analyser*

— a converter that reduces nitrogen dioxide to nitrogen monoxide, to determine the combined content of nitrogen monoxide and nitrogen dioxide. The efficiency of the converter has to be verified prior to use,
— a controlled-flow-rate ozone generator; the ozone is produced by high-voltage electric discharges across two electrodes; the ozone generator is supplied with pure oxygen or with dehydrated ambient air and the concentration of ozone obtained must greatly exceed the maximum content of any detectable nitrogen oxides,
— a chamber in which nitrogen monoxide and ozone can react,
— a system for detecting light radiation emitted at a wavelength of 1.2 µm, consisting of a selective optical filter and a photomultiplier tube.

H. Determination of Oxygen in Medicinal Gases

(Ph. Eur. method 2.5.27)

Oxygen in gases is determined using a paramagnetic analyser.

The principle of the method is based on the high paramagnetic sensitivity of the oxygen molecule. Oxygen exerts a strong interaction on magnetic fields, which is measured electronically, amplified and converted to a reading of oxygen concentration. The measurement of oxygen concentration is dependent upon the pressure and temperature and, if the analyser is not automatically compensated for variations in temperature and pressure, it must be calibrated immediately prior to use. As the paramagnetic effect of oxygen is linear, the instrument must have a suitable range with a readability of 0.1 per cent or better.

Calibration of the instrument Make the setting in the following manner:
— set the zero by passing *nitrogen R1* through the instrument until a constant reading is obtained;
— set the scale to 100 per cent by passing *oxygen R* through the instrument at the same flow rate as for *nitrogen R1* until a constant reading is obtained.

Assay Pass the gas to be examined through the instrument at a constant flow rate until a constant reading is obtained. Record the concentration of oxygen in the gas to be examined.

J. Determination of Water in Medicinal Gases

(Ph. Eur. method 2.5.28)

Water in gases is determined using an electrolytic hygrometer, described below.

The measuring cell consists of a thin film of diphosphorus pentoxide, between 2 coiled platinum wires which act as electrodes. The water vapour in the gas to be examined is absorbed by the diphosphorus pentoxide, which is transformed to phosphoric acid, an electrical conductor. A continuous voltage applied across the electrodes produces electrolysis of the water and the regeneration of the diphosphorus pentoxide. The resulting electric current, which is proportional to the water content in the gas to be examined, is measured. This system is self-calibrating since it obeys Faraday's law.

Take a sample of the gas to be examined. Allow the gas to stabilise at room temperature. Purge the cell continuously until a stable reading is obtained. Measure the water content in the gas to be examined, making sure that the temperature is constant throughout the device used to introduce the gas into the apparatus.

The electrolytic hygrometer achieves accurate sample flows by using a mass flow controller to deliver a constant volumetric flow rate to ensure that the water content is determined accurately. The calibration of the mass flow controller is normally performed using nitrogen. When using gases other than nitrogen for calibration, consult the manufacturer's instructions for the appropriate conversion factors and ensure that the correct cell is used for the type of gas to be examined.

K. Gas Detector Tubes

(Ph. Eur. method 2.1.6)

Gas detector tubes are cylindrical, sealed tubes consisting of an inert transparent material and are constructed to allow the passage of gas. They contain reagents adsorbed onto inert substrates that are suitable for the visualisation of the substance to be detected and, if necessary, they also contain preliminary layers and/or adsorbent filters to eliminate substances that interfere with the substance to be detected. The layer of indicator contains either a single reagent for the detection of a given impurity or several reagents for the detection of several substances (monolayer tube or multilayer tube).

The test is carried out by passing the required volume of the gas to be examined through the indicator tube. The length of the coloured layer or the intensity of a colour change on a graduated scale gives an indication of the impurities present.

The calibration of the detector tubes is verified according to the manufacturer's instructions.

Operating conditions Examine according to the manufacturer's instructions or proceed as follows.

The gas supply is connected to a suitable pressure regulator and needle valve. Connect the flexible tubing fitted with a Y-piece to the valve and adjust the flow of gas to be examined to purge the tubing in order to obtain an appropriate flow (Figure 2.1.6.-1). Prepare the indicator tube and fit to the metering pump, following the manufacturer's instructions. Connect the open end of the indicator tube to the short leg of the tubing and operate the pump by the appropriate number of strokes to pass a suitable volume of gas to be examined through the tube. Read the value corresponding to the length of the coloured layer or the intensity of the colour on the graduated scale. If a negative result is achieved, indicator tubes can be verified with a calibration gas containing the appropriate impurity.

In view of the wide variety of available compressor oils, it is necessary to verify the reactivity of the oil detector tubes for the oil used. Information on the reactivity for various oils is given in the leaflet supplied with the tube. If the oil used is not cited in the leaflet, the tube manufacturer must verify the reactivity and if necessary provide a tube specific for this oil.

Arsine detector tube

Sealed glass tube containing adsorbent filters and suitable supports for the gold salt or other appropriate indicator.

The minimum value indicated is 0.25 ppm or less, with a relative standard deviation of at most 20 per cent.

Carbon dioxide detector tube
Sealed glass tube containing adsorbent filters and suitable supports for hydrazine and crystal violet indicators. The minimum value indicated is 100 ppm with a relative standard deviation of at most 15 per cent.

Carbon monoxide detector tube
Sealed glass tube containing adsorbent filters and suitable supports for di-iodine pentoxide, selenium dioxide and fuming sulfuric acid indicators. The minimum value indicated is 5 ppm or less, with a relative standard deviation of at most 15 per cent.

Hydrogen sulfide detector tube
Sealed glass tube containing adsorbent filters and suitable supports for an appropriate lead salt indicator. The minimum value indicated is 0.2 ppm or less, with a relative standard deviation of at most 10 per cent.

Nitrogen monoxide and nitrogen dioxide detector tube
Sealed glass tube containing adsorbent filters and suitable supports for an oxidising layer (Cr(VI) salt) and the diphenylbenzidine indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most 15 per cent.

Oil detector tube
Sealed glass tube containing adsorbent filters and suitable supports for the sulfuric acid indicator. The minimum value indicated is 0.1 mg/m^3 with a relative standard deviation of at most 30 per cent.

Phosphine detector tube
Sealed glass tube containing adsorbent filters and suitable supports for the gold salt or other appropriate indicator. The minimum value indicated is 0.2 ppm or less, with a relative standard deviation of at most 20 per cent.

Sulfur dioxide detector tube
Sealed glass tube containing adsorbent filters and suitable supports for the iodine and starch indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most 15 per cent.

Water vapour detector tube
Sealed glass tube containing adsorbent filters and suitable supports for the magnesium perchlorate indicator. The minimum value indicated is 67 ppm or less, with a relative standard deviation of at most 20 per cent.

L. Determination of Nitrous Oxide in Gases

(Ph. Eur. method 2.5.35)

Gases absorb light at one or more specific wavelengths. This property is widely used to allow highly selective measurement of their concentrations.

Description and principle of measurement
The concentration of nitrous oxide in other gases can be determined using an infrared analyser.

The infrared analyser generally consists of a light source emitting broadband infrared radiation, an optical device, a sample cell and a detector. The optical device may be positioned either before or after the sample cell and it consists of one or several optical filters, through which the broadband radiation is passed. The optical device in this case is selected for nitrous oxide. The measurement light beam passes through the sample cell and may also pass through a reference cell if the analyser integrates such a feature (some use an electronic system instead of a reference cell).

When nitrous oxide is present in the sample cell, absorption of energy in the measurement light beam will occur according to the Beer-Lambert law and this produces a change in the detector signal. This measurement signal is compared to a reference signal to generate an output related to the concentration of nitrous oxide. The generated signal is linearised in order to obtain the nitrous oxide concentration. To prevent the entry of particles into the sensors, which could cause stray-light phenomena, the apparatus is fitted with a suitable filter.

M. Water-Solid Interactions: Determination of Sorption-Desorption Isotherms and of Water Activity[1]

(Ph. Eur. method 2.9.39)

INTRODUCTION
Pharmaceutical solids as raw materials or as constituents of dosage forms most often come in contact with water during processing and storage. This may occur (a) during crystallisation, lyophilisation, wet granulation, or spray drying; and (b) because of exposure upon handling and storage to an atmosphere containing water vapour or exposure to other materials in a dosage form that contain water capable of distributing it to other ingredients. Some properties known to be altered by the association of solids with water include rates of chemical degradation in the "solid-state", crystal growth and dissolution, dispersibility and wetting, powder flow, lubricity, powder compactibility, compact hardness and microbial contamination.

Although precautions can be taken when water is perceived to be a problem, i.e. eliminating all moisture, reducing contact with the atmosphere, or controlling the relative humidity of the atmosphere, such precautions generally add expense to the process with no guarantee that during the life of the product further problems associated with moisture will be avoided. It is also important to recognise that there are many situations where a certain level of water in a solid is required for proper performance, e.g. powder compaction.

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8. Pharmacopoeial harmonisation.*

It is essential for both reasons, therefore, that as much as possible is known about the effects of moisture on solids before strategies are developed for their handling, storage and use.

Some of the more critical pieces of required information concerning water-solid interactions are:

- total amount of water present;
- the extent to which adsorption and absorption occur;
- whether or not hydrates form;
- specific surface area of the solid, as well as such properties as degree of crystallinity, degree of porosity, and glass transition and melting temperature;
- site of water interaction, the extent of binding, and the degree of molecular mobility;
- effects of temperature and relative humidity;
- essentially irreversible hydration;
- kinetics of moisture uptake;
- various factors that might influence the rate at which water vapour can be taken up by a solid;
- for water-soluble solids capable of being dissolved by the sorbed water, under which conditions dissolution will take place.

PHYSICAL STATES OF SORBED WATER

Water can physically interact with solids in different ways. It can interact at the surface (adsorption) or it can penetrate the bulk solid structure (absorption). When both adsorption and absorption occur, the term sorption is often used. Adsorption is particularly critical in affecting the properties of solids when the specific surface area is large. Large values of specific surface area are seen with solids having very small particles, as well as with solids having a high degree of intraparticle porosity. Absorption is characterised by an association of water per gram of solid that is much greater than that which can form a monomolecular layer on the available surface, and an amount that is generally independent of the specific surface area.

Most crystalline solids will not absorb water into their bulk structures because of the close packing and high degree of order of the crystal lattice. Indeed, it has been shown that the degree of absorption into solids exhibiting partial crystallinity and partial amorphous structure is often inversely proportional to the degree of crystallinity. With some crystalline solids, however, crystal hydrates may form. These hydrates may exhibit a stoichiometric relationship, in terms of water molecules bound per solid molecule, or they may be non-stoichiometric. Upon dehydration, crystal hydrates may either retain their original crystal structure, or lose their crystallinity and become amorphous, or transform into a new anhydrous or less-hydrated crystal form.

Amorphous or partially amorphous solids are capable of taking up significant amounts of water because there is sufficient molecular disorder in the solid to permit penetration, swelling or dissolution. Such behaviour is observed with most amorphous polymers and with small-molecular-mass solids rendered amorphous during preparation, e.g. by lyophilisation, or after milling. The introduction of defects into highly crystalline solids will also produce this behaviour. The greater the chemical affinity of water for the solid, the greater the total amount that can be absorbed. When water is absorbed by amorphous solids, the bulk properties of the solid can be significantly altered. It is well established, for example, that amorphous solids, depending on the temperature, can exist in at least one of 2 states, "glassy" or "fluid"; the temperature at which one state transforms into the other is the glass transition temperature, T_g.

Water absorbed into the bulk solid structure, by virtue of its effect on the free volume of the solid, can act as an efficient plasticiser and reduce the value of T_g. Since the rheological properties of "fluid" and "glassy" states are quite different, i.e. the "fluid" state exhibits much less viscosity as one goes increasingly above the glass transition temperature, it is not surprising that a number of important bulk properties dependent on the rheology of the solid are affected by moisture content. Since amorphous solids are metastable relative to the crystalline form of the material, with small-molecular-mass materials, it is possible for absorbed moisture to initiate reversion of the solid to the crystalline form, particularly if the solid is transformed by the sorbed water to a "fluid" state. This is the basis of "cake collapse" often observed during the lyophilisation process. An additional phenomenon noted specifically with water-soluble solids is their tendency to deliquesce, i.e. to dissolve in their own sorbed water, at relative humidities, RH_i, in excess of the relative humidity of a saturated solution of the solid, RH_0. Deliquescence arises because of the high water solubility of the solid and the significant effect it has on the colligative properties of water. It is a dynamic process that continues to occur as long as RH_i is greater than RH_0.

The key to understanding the effects water can have on the properties of solids, and vice versa, rests with an understanding of the location of the water molecule and its physical state. More specifically, water associated with solids can exist in a state that is directly bound to the solid, as well as in a state of mobility approaching that of bulk water. This difference in mobility has been observed through such measurements as heats of sorption, freezing point, nuclear magnetic resonance, dielectric properties and diffusion. Such changes in mobility have been interpreted as arising because of changes in the thermodynamic state of water as more and more water is sorbed. Thus, water bound directly to a solid is often thought as unavailable to affect the properties of the solid, whereas larger amounts of sorbed water may become more clustered and form water more like that exhibiting solvent properties. In the case of crystal hydrates, the combination of intermolecular forces (hydrogen bonding) and crystal packing can produce very strong water-solid interactions. Recognising that the presence of water in an amorphous solid can affect the glass transition temperature and hence the physical state of the solid, at low levels of water, most polar amorphous solids are in a highly viscous glassy state because of their high values of T_g. Hence, water is "frozen" into the solid structure and is rendered immobile by the high viscosity, e.g. 10^{13} Pa·s. As the amount of water sorbed increases and T_g decreases, approaching ambient temperatures, the glassy state approaches that of a "fluid" state and water mobility along with the mobility of the solid itself increases significantly. At high RH, the degree of water plasticisation of the solid can be sufficiently high so that water and the solid can now achieve significant amounts of mobility. In general, therefore, this picture of the nature of sorbed water helps to explain the rather significant effect moisture can have on a number of bulk properties of solids such as chemical reactivity and mechanical deformation. It suggests strongly that methods of evaluating chemical and physical stability of solids and solid dosage forms take into account the effects water can have on the solid when it is sorbed, particularly when it enters the solid structure and acts as a plasticiser.

Figure 2.9.39.-1. – *Example of an apparatus for the determination of the water sorption (other designs are possible)*

Rates of water uptake

The rate and extent to which solids exposed to the atmosphere might either sorb or desorb water vapour can be a critical factor in the handling of solids. Even the simple act of weighing out samples of solid on an analytical balance and the exposure, therefore, of a thin layer of powder to the atmosphere for a few minutes can lead to significant error in, for example, the estimation of loss on drying values. It is well established that water-soluble solids exposed to relative humidities above that exhibited by a saturated solution of that solid will spontaneously dissolve via deliquescence and continue to dissolve over a long time period. The rate of water uptake in general depends on a number of parameters not found to be critical in equilibrium measurements because rates of sorption are primarily mass-transfer controlled with some contributions from heat-transfer mechanisms. Thus, factors such as vapour diffusion coefficients in air and in the solid, convective airflow, and the surface area and geometry of the solid bed and surrounding environment, can play an important role. Indeed, the method used to make measurements can often be the rate-determining factor because of these environmental and geometric factors.

DETERMINATION OF SORPTION-DESORPTION ISOTHERMS

Principle

The tendency to take up water vapour is best assessed by measuring sorption or desorption as a function of relative humidity, at constant temperature, and under conditions where sorption or desorption is essentially occurring independently of time, i.e. equilibrium. Relative humidity, *RH*, is defined by the following expression:

$$\frac{P_c}{P_0} \times 100$$

P_c = pressure of water vapour in the system;
P_0 = saturation pressure of water vapour under the same conditions.

The ratio P_c/P_0 is referred to as the relative pressure. Sorption or water uptake is best assessed starting with dried samples and subjecting them to a known relative humidity. Desorption is studied by beginning with a system already containing sorbed water and reducing the relative humidity. As the name indicates, the sorption-desorption isotherm is valid only for the reference temperature, hence a special isotherm exists for each temperature. Ordinarily, at equilibrium, moisture content at a particular relative humidity must be the same, whether determined from sorption or desorption measurements. However, it is common to see sorption-desorption hysteresis.

Methods

Samples may be stored in chambers at various relative humidities (Figure 2.9.39.-1). The mass gained or lost for each sample is then measured. The major advantage of this method is convenience, while the major disadvantages are the slow rate of reaching constant mass, particularly at high relative humidities, and the error introduced in opening and closing the chamber for weighing.

Dynamic gravimetric water sorption systems allow the on-line weighing of a sample in a controlled system to assess the interaction of the material with moisture at various programmable levels of relative humidity at a constant temperature. The major benefit of a controlled system is that isothermal conditions can be more reliably established and that the dynamic response of the sample to changing conditions can be monitored. Data points for the determination of the sorption isotherm (e.g. from 0 per cent to approximately 95 per cent *RH*, non condensing) are only taken after a sufficiently constant signal indicates that the sample has reached equilibrium at a given level of humidity. In some cases (e.g. deliquescence), the maximum time may be restricted although the equilibrium level is not reached. The apparatus must adequately control the temperature to ensure a good baseline stability as well as accurate control of

the relative humidity generation. The required relative humidities can be generated, e.g. by accurately mixing dry and saturated vapour gas with flow controllers.
The electrostatic behaviour of the powder must also be considered. The verification of the temperature and the relative humidity (controlled with, for example, a certified hygrometer, certified salt solutions or deliquescence points of certified salts over an adequate range), must be consistent with the instrument specification. The balance must provide a sufficient mass resolution and long term stability.

It is also possible to measure amounts of water uptake not detectable gravimetrically using volumetric techniques.
In some cases, direct analysis of water content by different methods such as determination of the boiling point, determination of water by distillation, loss on drying or gas chromatography may be advantageous. In the case of adsorption, to improve sensitivity, one can increase the specific surface area of the sample by reducing particle size or by using larger samples to increase the total area. It is important, however, that such comminution of the solid does not alter the surface structure of the solid or render it more amorphous or otherwise less ordered in crystallinity.
For absorption, where water uptake is independent of specific surface area, only increasing sample size will help. Increasing sample size, however, will increase the time to establish some type of equilibrium. To establish accurate values, it is important to get desolvation of the sample as thoroughly as possible. Higher temperatures and lower pressures (vacuum) facilitate this process; however, one must be aware of any adverse effects this might have on the solid such as dehydration, chemical degradation or sublimation. Using higher temperatures to induce desorption, as in a thermogravimetric apparatus, likewise must be carefully carried out because of these possible pitfalls.

Report and interpretation of the data
Sorption data are usually reported as a graph of the apparent mass change in per cent of the mass of the dry sample as a function of relative humidity or time. Sorption isotherms are reported both in tabular form and as a graph.
The measurement method must be traceable with the data.

Adsorption-desorption hysteresis can be interpreted, for example, in terms of the porosity of the sample, its state of agglomeration (capillary condensation), the formation of hydrates, polymorphic change, or liquefying of the sample. Certain types of systems, particularly those with microporous solids and amorphous solids, are capable of sorbing large amounts of water vapour. Here, the amount of water associated with the solid as relative humidity is decreased, is greater than the amount that originally sorbed as the relative humidity was increased. For microporous solids, vapour adsorption-desorption hysteresis is an equilibrium phenomenon associated with the process of capillary condensation. This takes place because of the high degree of irregular curvature of the micropores and the fact that they "fill" (adsorption) and "empty" (desorption) under different equilibrium conditions. For non-porous solids capable of absorbing water, hysteresis occurs because of a change in the degree of vapour-solid interaction due to a change in the equilibrium state of the solid, e.g. conformation of polymer chains, or because the time scale for structural equilibrium is longer than the time scale for water desorption. In measuring sorption-desorption isotherms, it is therefore important to establish that something close to an equilibrium state has been reached. Particularly with hydrophilic polymers at high relative humidities, the establishment of water sorption or desorption values independent of time is quite difficult, since one is usually dealing with a polymer plasticised into its "fluid" state, where the solid is undergoing significant change.

In the case of crystal hydrate formation, the plot of water uptake versus pressure or relative humidity will in these cases exhibit a sharp increase in uptake at a particular pressure and the amount of water taken up will usually exhibit a stoichiometric mole:mole ratio of water to solid. In some cases, however, crystal hydrates will not appear to undergo a phase change or the anhydrous form will appear amorphous. Consequently, water sorption or desorption may appear more like that seen with adsorption processes. X-ray crystallographic analysis and thermal analysis are particularly useful for the study of such systems.

For situations where water vapour adsorption occurs predominantly, it is very helpful to measure the specific surface area of the solid by an independent method and to express adsorption as mass of water sorbed per unit area of solid surface. This can be very useful in assessing the possible importance of water sorption in affecting solid properties. For example, 0.5 per cent *m/m* uptake of water could hardly cover the bare surface of 100 m^2/g, while for 1.0 m^2/g this amounts to 100 times more surface coverage. In the case of pharmaceutical solids which have a specific surface area in the range of 0.01 m^2/g to 10 m^2/g, what appears to be low water content could represent a significant amount of water for the available surface. Since the "dry surface area" is not a factor in absorption, sorption of water with amorphous or partially amorphous solids can be expressed on the basis of unit mass corrected for crystallinity, when the crystal form does not sorb significant amounts of water relative to the amorphous regions.

DETERMINATION OF THE WATER ACTIVITY

Principle
Water activity, A_w, is the ratio of vapour pressure of water in the product (P) to saturation pressure of water vapour (P_0) at the same temperature. It is numerically equal to 1/100 of the relative humidity (*RH*) generated by the product in a closed system. *RH* can be calculated from direct measurements of partial vapour pressure or dew point, or from indirect measurement by sensors whose physical or electric characteristics are altered by the *RH* to which they are exposed. Ignoring activity coefficients, the relationship between A_w and equilibrium relative humidity (*ERH*) are represented by the following equations:

$$A_w = \frac{P}{P_0}$$

$$ERH \text{ (per cent)} = A_w \times 100$$

Method
The water activity is determined by placing the sample in a small airtight cup inside which the equilibrium between the water in the solid and the headspace can be established. The volume of the headspace must be small in relation to the sample volume in order not to change the sorption state of sample during the test. The equilibration as a thermodynamic process takes time but may be accelerated by forced circulation within the cell. The acquired water activity value is only valid for the simultaneously determined temperature. This requires a precise temperature-measuring device as part of the equipment. Furthermore, the probe must be thermally insulated to guarantee a constant temperature during the test. The sensor measuring the humidity of the headspace air above the sample is a key

component. Theoretically, all types of hygrometers can be used, but for analytical purposes miniaturisation and robustness are a precondition. The A_w measurement may be conducted using the dew point/chilled mirror method[2]. A polished, chilled mirror is used as a condensing surface. The cooling system is electronically linked to a photoelectric cell into which light is reflected from the condensing mirror. An air stream, in equilibrium with the test sample, is directed at the mirror, which cools until condensation occurs on the mirror. The temperature at which this condensation begins is the dew point from which the *ERH* is determined. Commercially available instruments using the dew point/chilled mirror method or other technologies need to be evaluated for suitability, qualified, and calibrated when used to make water activity determinations. These instruments are typically calibrated over an adequate range, for example, using some saturated salt solutions at 25 °C such as those listed in Table 2.9.39.-1.

Table 2.9.39.-1. – *Standard saturated salt solutions*

Saturated salts solutions at 25 °C	*ERH* (per cent)	A_w
Potassium sulfate (K_2SO_4)	97.3	0.973
Barium chloride ($BaCl_2$)	90.2	0.902
Sodium chloride (NaCl)	75.3	0.753
Magnesium nitrate ($Mg(NO_3)_2$)	52.9	0.529
Magnesium chloride ($MgCl_2$)	32.8	0.328
Lithium chloride (LiCl)	11.2	0.112

[2] *AOAC International Official Method 978.18.*

Appendix X

A. Acetyl Value

(No Ph. Eur. method)

The acetyl value of a substance is the number of mg of potassium hydroxide required to neutralise the acetic acid liberated by the hydrolysis of 1 g of the acetylated substance.

Determine the *saponification value*, Appendix X G.

Acetylate by the following method. To 10 g in a 200-mL Kjeldahl flask add 20 mL of *acetic anhydride*. Support the flask on a sheet of heat resistant material in which a hole about 4 cm in diameter has been cut and heat with a small, naked flame, not more than 25 mm in height and which does not impinge on the bottom of the flask. Boil gently under a reflux air condenser for 2 hours, allow to cool, pour into 600 mL of *water* contained in a large beaker, add 0.2 g of *pumice powder* and boil for 30 minutes. Cool, transfer to a separating funnel and discard the lower layer. Wash the acetylated product with three or more 50-mL quantities of a warm, saturated solution of *sodium chloride* until the washings are no longer acidic to *litmus paper*. Finally shake with 20 mL of warm *water* and remove the aqueous layer as completely as possible. Pour the acetylated substance into a small dish, add 1 g of powdered *anhydrous sodium sulfate*, stir thoroughly and filter through a dry, pleated filter paper. Determine the *saponification value* of the acetylated substance.

Calculate the acetyl value from the expression $1335(b-a)/(1335-a)$ where a is the saponification value of the substance and b is the saponification value of the acetylated substance.

B. Acid Value

(Ph. Eur. method 2.5.1)

The acid value I_A is the number that expresses, in milligrams the quantity of potassium hydroxide required to neutralise the free acids present in 1 g of the substance.

Dissolve 10.00 g of the substance to be examined, or the quantity prescribed, (m g), in 50 mL of a mixture of equal volumes of *ethanol (96 per cent) R* and *light petroleum R3*, previously neutralised with *0.1 M potassium hydroxide* or *0.1 M sodium hydroxide*, unless otherwise specified, using 0.5 mL of *phenolphthalein solution R1* as indicator.

If necessary, heat to about 90 °C to dissolve the substance to be examined. When the substance to be examined has dissolved, titrate with *0.1 M potassium hydroxide* or *0.1 M sodium hydroxide* until the pink colour persists for at least 15 s (n mL of titrant). When heating has been applied to aid dissolution, maintain the temperature at about 90 °C during the titration.

$$I_A = \frac{5.611n}{m}$$

C. Ester Value

(Ph. Eur. method 2.5.2)

The ester value I_E is the number that expresses in milligrams the quantity of potassium hydroxide required to saponify the esters present in 1 g of the substance. It is calculated from the saponification value I_S and the acid value I_A:

$$I_E = I_S - I_A$$

D. Hydroxyl Value

(Ph. Eur. method 2.5.3)

The hydroxyl value I_{OH} is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the acid combined by acylation in 1 g of the substance.

METHOD A

Introduce the quantity of the substance to be examined shown in Table 2.5.3.-1 (m g) into a 150 mL acetylation flask fitted with an air condenser, unless another quantity is prescribed in the monograph. Add the quantity of *acetic anhydride solution R1* stated in Table 2.5.3.-1 and attach the air condenser.

Table 2.5.3.-1

Presumed value I_{OH}	Quantity of sample (g)	Volume of acetylating reagent (mL)
10 - 100	2.0	5.0
100 - 150	1.5	5.0
150 - 200	1.0	5.0
200 - 250	0.75	5.0
250 - 300	0.60 or 1.20	5.0 or 10.0
300 - 350	1.0	10.0
350 - 700	0.75	15.0
700 - 950	0.5	15.0

Heat the flask in a water-bath for 1 h keeping the level of the water about 2.5 cm above the level of the liquid in the flask. Withdraw the flask and allow to cool. Add 5 mL of *water R* through the upper end of the condenser. If a cloudiness appears add sufficient *pyridine R* to clear it, noting the volume added. Shake the flask and replace in the water-bath for 10 min. Withdraw the flask and allow to cool. Rinse the condenser and the walls of the flask with 5 mL of *alcohol R*, previously neutralised to *phenolphthalein solution R1*. Titrate with 0.5 M alcoholic potassium hydroxide using 0.2 mL of *phenolphthalein solution R1* as indicator (n_1 mL of 0.5 M alcoholic potassium hydroxide). Carry out a blank test under the same conditions (n_2 mL of 0.5 M alcoholic potassium hydroxide).

$$I_{OH} = \frac{28.05(n_2 - n_1)}{m} + I_A$$

METHOD B

Introduce the prescribed quantity of the substance to be examined (m g) into a perfectly dry 5 mL conical flask fitted with a ground-glass or suitable plastic stopper and add 2.0 mL of *propionic anhydride reagent R*. Close the flask and shake gently to dissolve the substance. Allow to stand for 2 h unless otherwise prescribed. Remove the stopper and transfer the flask and its contents into a wide-mouthed 500 mL conical flask containing 25.0 mL of a 9 g/L solution of *aniline R* in *cyclohexane R* and 30 mL of *glacial acetic acid R*. Swirl the contents of the flask, allow to stand for 5 min, add 0.05 mL of *crystal violet solution R* and titrate with *0.1 M perchloric acid* until an emerald-green colour is obtained (n_1 mL of *0.1 M perchloric acid*). Carry out a blank test under the same conditions (n_2 mL of *0.1 M perchloric acid*).

$$I_{OH} = \frac{5.610(n_1 - n_2)}{m}$$

To take account of any water present, determine this (y per cent) by the semi-micro determination of water (*2.5.12*).

The hydroxyl value is then given by the equation:

$$I_{OH} = \text{(hydroxyl value as determined)} - 31.1y$$

E. Iodine Value

(Ph. Eur. method 2.5.4)

The iodine value I_I is the number that expresses in grams the quantity of halogen, calculated as iodine, that can be fixed in the prescribed conditions by 100 g of the substance.

When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.

METHOD A

Unless otherwise prescribed, use the following quantities (Table 2.5.4.-1) for the determination.

Table 2.5.4.-1

Presumed value I_I	Quantity of sample (g)
less than 20	1.0
20 - 60	0.5 - 0.25
60 - 100	0.25 - 0.15
more than 100	0.15 - 0.10

Introduce the prescribed quantity of the substance to be examined (m g) into a 250 mL flask fitted with a ground-glass stopper and previously dried or rinsed with *glacial acetic acid R*, and dissolve it in 15 mL of *chloroform R* unless otherwise prescribed. Add very slowly 25.0 mL of *iodine bromide solution R*. Close the flask and keep it in the dark for 30 min unless otherwise prescribed, shaking frequently. Add 10 mL of a 100 g/L solution of *potassium iodide R* and 100 mL of *water R*. Titrate with *0.1 M sodium thiosulfate*, shaking vigorously until the yellow colour is almost discharged. Add 5 mL of *starch solution R* and continue the titration adding the *0.1 M sodium thiosulfate* dropwise until the colour is discharged (n_1 mL of *0.1 M sodium thiosulfate*). Carry out a blank test under the same conditions (n_2 mL of *0.1 M sodium thiosulfate*).

$$I_I = \frac{1.269\ (n_2 - n_1)}{m}$$

METHOD B

Unless otherwise prescribed, use the following quantities (Table 2.5.4.-2) for the determination.

Table 2.5.4.-2

Presumed value I_I	Mass (g) (corresponding to an excess of 150 per cent ICl)	Mass (g) (corresponding to an excess of 100 per cent ICl)	Iodine chloride solution (mL)
<3	10	10	25
3	8.4613	10.5760	25
5	5.0770	6.3460	25
10	2.5384	3.1730	20
20	0.8461	1.5865	20
40	0.6346	0.7935	20
60	0.4321	0.5288	20
80	0.3173	0.3966	20
100	0.2538	0.3173	20
120	0.2115	0.2644	20
140	0.1813	0.2266	20
160	0.1587	0.1983	20
180	0.1410	0.1762	20
200	0.1269	0.1586	20

The mass of the sample is such that there will be an excess of *iodine chloride solution R* of 50 per cent to 60 per cent of the amount added, i.e. 100 per cent to 150 per cent of the amount absorbed.

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 mL flask fitted with a ground-glass stopper and previously rinsed with *glacial acetic acid R* or dried, and dissolve it in 15 mL of a mixture of equal volumes of *cyclohexane R* and *glacial acetic acid R*, unless otherwise prescribed. If necessary, melt the substance before dissolution (melting point greater than 50 °C). Add very slowly the volume of *iodine chloride solution R* stated in Table 2.5.4.-2. Close the flask and keep it in the dark for 30 min, unless otherwise prescribed, shaking frequently. Add 10 mL of a 100 g/L solution of *potassium iodide R* and 100 mL of *water R*. Titrate with *0.1 M sodium thiosulfate*, shaking vigorously until the yellow colour is almost discharged. Add 5 mL of *starch solution R* and continue the titration adding the *0.1 M sodium thiosulfate* dropwise until the colour is discharged (n_1 mL of *0.1 M sodium thiosulfate*). Carry out a blank test under the same conditions (n_2 mL of *0.1 M sodium thiosulfate*).

$$I_I = \frac{1.269\ (n_2 - n_1)}{m}$$

Iodine Monochloride Method

(No Ph. Eur. method)

When the use of iodine flasks is prescribed, use flasks with a nominal capacity of 250 mL and complying with British Standard 2735:1956 (Specification for iodine flasks), unless otherwise specified.

Dissolve the specified quantity of the substance being examined in 10 mL of *dichloromethane* in a dry iodine flask. Add 20 mL of *iodine monochloride solution*, insert the stopper, previously moistened with *dilute potassium iodide solution*, and allow to stand in the dark at 15° to 25° for 30 minutes. Place 15 mL of *dilute potassium iodide solution* in the top cup, carefully remove the stopper, rinse the stopper and the sides of the flask with 100 mL of *water*, shake and titrate with 0.1M *sodium thiosulfate VS* using *starch mucilage*, added towards the end of the titration, as indicator. At the same time carry out the operation in exactly the same manner, but without the substance being examined.

Calculate the iodine value from the expression 1.269 *v/w* where *v* is the difference, in mL, between the titrations and *w* is the weight, in g, of the substance taken.

The approximate weight, in g, of the substance to be taken may be calculated by dividing 20 by the highest expected iodine value. If more than half of the available halogen is absorbed, the test must be repeated, using a smaller quantity of the substance.

F. Peroxide Value

(Ph. Eur. method 2.5.5)

The peroxide value I_P is the number that expresses in milliequivalents of active oxygen the quantity of peroxide contained in 1000 g of the substance, as determined by the methods described below.

When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.

METHOD A

Place 5.00 g of the substance to be examined (*m* g) in a 250 mL conical flask fitted with a ground-glass stopper. Add 30 mL of a mixture of 2 volumes of *chloroform R* and 3 volumes of *glacial acetic acid R*. Shake to dissolve the substance and add 0.5 mL of *saturated potassium iodide solution R*. Shake for exactly 1 min then add 30 mL of *water R*. Titrate with *0.01 M sodium thiosulfate*, adding the titrant slowly with continuous vigorous shaking, until the yellow colour is almost discharged. Add 5 mL of *starch solution R* and continue the titration, shaking vigorously, until the colour is discharged (n_1 mL of *0.01 M sodium thiosulfate*). Carry out a blank test under the same conditions (n_2 mL of *0.01 M sodium thiosulfate*). The volume of *0.01 M sodium thiosulfate* used in the blank titration must not exceed 0.1 mL.

$$I_p = \frac{10(n_1 - n_2)}{m}$$

METHOD B

Carry out the operations avoiding exposure to actinic light.

Place 50 mL of a mixture of 2 volumes of *trimethylpentane R* and 3 volumes of *glacial acetic acid R* in a conical flask and replace the stopper. Swirl the flask until the substance to be examined (*m* g; see Table 2.5.5.-1) has dissolved. Using a suitable volumetric pipette, add 0.5 mL of *saturated potassium iodide solution R* and replace the stopper. Allow the solution to stand for 60 ± 1 s, thoroughly shaking the solution continuously, then add 30 mL of *water R*.

Table 2.5.5.-1

Expected peroxide value I_p	Mass of substance to be examined (g)
0 to 12	5.00 to 2.00
12 to 20	2.00 to 1.20
20 to 30	1.20 to 0.80
30 to 50	0.800 to 0.500
50 to 90	0.500 to 0.300

Titrate the solution with *0.01 M sodium thiosulfate* (V_1 mL), adding it gradually and with constant, vigorous shaking, until the yellow iodine colour has almost disappeared. Add about 0.5 mL of *starch solution R1* and continue the titration, with constant shaking especially near the end-point, to liberate all of the iodine from the solvent layer. Add the sodium thiosulfate solution dropwise until the blue colour just disappears.

Depending on the volume of *0.01 M sodium thiosulfate* used, it may be necessary to titrate with *0.1 M sodium thiosulfate*.

NOTE There is a 15 s to 30 s delay in neutralising the starch indicator for peroxide values of 70 and greater, due to the tendency of trimethylpentane to float on the surface of the aqueous medium and the time necessary to adequately mix the solvent and the aqueous titrant, thus liberating the last traces of iodine. It is recommended to use *0.1 M sodium thiosulfate* for peroxide values greater than 150. A small amount (0.5 per cent to 1.0 per cent *m/m*) of high HLB emulsifier (for example polysorbate 60) may be added to the mixture to retard the phase separation and decrease the time lag in the liberation of iodine.

Carry out a blank determination (V_0 mL). If the result of the blank determination exceeds 0.1 mL of titration reagent, replace the reagents and repeat the determination.

$$I_p = \frac{1000(V_1 - V_0)c}{m}$$

c = concentration of the sodium thiosulfate solution, in moles per litre.

G. Saponification Value

The saponification value is the number of mg of potassium hydroxide required to neutralise the free acids and to saponify the esters in 1 g of the substance.

Use Method I unless otherwise specified in the monograph.

Method I

(No Ph. Eur. method)

Dissolve 35 to 40 g of *potassium hydroxide* in 20 mL of *water* and add sufficient *ethanol (96%)* to produce 1000 mL. Allow to stand overnight and pour off the clear liquid.

Weigh 2 g of the substance into a 200-mL flask, add 25.0 mL of the ethanolic solution of potassium hydroxide and boil under a reflux condenser for 1 hour, rotating the contents frequently. While the solution is still hot, titrate the excess of alkali with 0.5M *hydrochloric acid VS* using 1 mL of *phenolphthalein solution R1* as indicator. Repeat the operation without the substance being examined.

Calculate the saponification value from the expression 28.05 *v/w* where *v* is the difference, in mL, between the titrations and *w* is the weight, in g, of substance taken.

Method II

(Ph. Eur. method 2.5.6)

The saponification value I_S is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the free acids and to saponify the esters present in 1 g of the substance.

Unless otherwise prescribed, use the quantities indicated in Table 2.5.6.-1 for the determination.

Table 2.5.6.-1

Presumed value I_S	Quantity of sample (g)
<3	20
3 to 10	12 to 15
10 to 40	8 to 12
40 to 60	5 to 8
60 to 100	3 to 5
100 to 200	2.5 to 3
200 to 300	1 to 2
300 to 400	0.5 to 1

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 mL borosilicate glass flask fitted with a reflux condenser. Add 25.0 mL of 0.5 M alcoholic potassium hydroxide and a few glass beads. Attach the condenser and heat under reflux for 30 min, unless otherwise prescribed. Add 1 mL of *phenolphthalein solution R1* and titrate immediately (while still hot) with *0.5 M hydrochloric acid* (n_1 mL of *0.5 M hydrochloric acid*). Carry out a blank test under the same conditions (n_2 mL of *0.5 M hydrochloric acid*).

$$I_S = \frac{28.05(n_2 - n_1)}{m}$$

H. Unsaponifiable Matter

The unsaponifiable matter is the percentage content, w/w, of material not volatile at 100° to 105° that is obtained by extraction with an organic solvent from the saponified substance being examined.

Use Method I unless otherwise specified in the monograph.
Use ungreased ground-glass glassware for each method.

Method I

(No Ph. Eur. method)

To 2.0 to 2.5 g of the substance being examined in a 250-mL flask add 25 mL of 0.5M *ethanolic potassium hydroxide* and boil under a reflux condenser in a water-bath for 1 hour, swirling the contents frequently. Wash the contents of the flask into a separating funnel with the aid of 50 mL of *water* and, while the liquid is still slightly warm, extract by shaking vigorously with three 50-mL quantities of *peroxide-free ether*, rinsing the flask with the first quantity of ether. Mix the ether solutions in a separating funnel containing 20 mL of *water*. (If the ether solutions contain solid suspended matter, filter them into the separating funnel through a fat-free filter paper and wash the filter paper with *peroxide-free ether*.) Gently rotate the separating funnel for a few minutes without violent shaking, allow the liquids to separate and discard the aqueous layer. Wash the ether solution by shaking vigorously with two 20-mL quantities of *water* and then treat with three 20-mL quantities of 0.5M *potassium hydroxide*, shaking vigorously on each occasion, each treatment being followed by washing with 20 mL of *water*. Finally wash with successive 20-mL quantities of *water* until the aqueous layer is no longer alkaline to *phenolphthalein solution R1*. Transfer the ether extract to a weighed flask, rinsing the separating funnel with *peroxide-free ether*, distil the ether and add 3 mL of *acetone* to the flask. With the aid of a gentle current of air, remove the solvent completely from the flask, which is almost entirely immersed in boiling water and preferably held obliquely and rotated. Dry to constant weight at a temperature not exceeding 80° and dissolve the contents of the flask in 10 mL of freshly boiled *ethanol (96%)*, previously neutralised to *phenolphthalein solution R1*. Titrate with 0.1M *ethanolic sodium hydroxide VS* using *phenolphthalein solution R1* as indicator.

If the volume of 0.1M *ethanolic sodium hydroxide VS* required does not exceed 0.1 mL, the amount of residue weighed is to be taken as the unsaponifiable matter. Calculate the unsaponifiable matter as a percentage of the substance being examined.

If the volume of 0.1M *ethanolic sodium hydroxide VS* required exceeds 0.1 mL, the amount of residue weighed cannot be taken as the unsaponifiable matter and the test must be repeated.

Method II

(Ph. Eur. method 2.5.7)

The term "unsaponifiable matter" is applied to the substances non-volatile at 100-105 °C obtained by extraction with an organic solvent from the substance to be examined after it has been saponified. The result is calculated as per cent *m/m*.

Use ungreased ground-glass glassware.

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 mL flask fitted with a reflux condenser. Add 50 mL of *2 M alcoholic potassium hydroxide R* and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the

flask to a separating funnel with the aid of 100 mL of *water R*. Shake the liquid carefully with 3 quantities, each of 100 mL, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 mL of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with 2 quantities, each of 40 mL, of *water R* then wash successively with 40 mL of a 30 g/L solution of *potassium hydroxide R* and 40 mL of *water R*; repeat this procedure 3 times. Wash the ether phase several times, each with 40 mL of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*.

Distil off the ether with suitable precautions and add 6 mL of *acetone R* to the residue. Carefully remove the solvent in a current of air. Dry to constant mass at 100-105 °C. Allow to cool in a desiccator and weigh (*a* g).

$$\text{Unsaponifiable matter} = \frac{100a}{m} \text{ per cent}$$

Dissolve the residue in 20 mL of *alcohol R*, previously neutralised to *phenolphthalein solution R* and titrate with *0.1 M ethanolic sodium hydroxide*. If the volume of *0.1 M ethanolic sodium hydroxide* used is greater than 0.2 mL, the separation of the layers has been incomplete; the residue weighed cannot be considered as "unsaponifiable matter". In case of doubt, the test must be repeated.

J. Determination of Cineole

(Ph. Eur. method 2.8.11)

Weigh 3.00 g of the oil, recently dried with *anhydrous sodium sulfate R*, into a dry test-tube and add 2.10 g of melted *cresol R*. Place the tube in the apparatus for the determination of freezing point (*2.2.18*) and allow to cool, stirring continuously. When crystallisation takes place there is a small rise in temperature. Note the highest temperature reached (t_1).

Remelt the mixture on a water-bath at a temperature that does not exceed t_1 by more than 5 °C and place the tube in the apparatus, maintained at a temperature 5 °C below t_1. When crystallisation takes place, or when the temperature of the mixture has fallen 3 °C below t_1, stir continuously. Note the highest temperature at which the mixture crystallises (t_2). Repeat the operation until 2 highest values obtained for t_2 do not differ by more than 0.2 °C. If supercooling occurs, induce crystallisation by adding a small crystal of the complex consisting of 3.00 g of *cineole R* and 2.10 g of melted *cresol R*. If t_2 is below 27.4 °C, repeat the determination after the addition of 5.10 g of the complex.

The content of cineole corresponding to the highest temperature observed (t_2) is given in Table 2.8.11.-1. If 5.10 g of the complex has been added, calculate the cineole content per cent *m/m* from the expression:

$$2(A - 50)$$

where A is the value found in Table 2.8.11.-1.

The content of cineole, corresponding to the highest temperature observed (t_2), is obtained, where necessary, by interpolation.

Table 2.8.11.-1

t_2 °C	cineole per cent *m/m*	t_2 °C	cineole per cent *m/m*	t_2 °C	cineole per cent *m/m*	t_2 °C	cineole per cent *m/m*
24	45.5	32	56.0	40	67.0	48	82.0
25	47.0	33	57.0	41	68.5	49	84.0
26	48.5	34	58.5	42	70.0	50	86.0
27	49.5	35	60.0	43	72.5	51	88.5
28	50.5	36	61.0	44	74.0	52	91.0
29	52.0	37	62.5	45	76.0	53	93.5
30	53.5	38	63.5	46	78.0	54	96.0
31	54.5	39	65.0	47	80.0	55	99.0

K. Determination of Aldehydes

(No Ph. Eur. method)

To 1 g of the oil in a glass-stoppered tube (approximately 150 mm × 25 mm) add 5 mL of *toluene* and 15 mL of *alcoholic hydroxylamine solution*, shake vigorously and titrate immediately with 0.5M *potassium hydroxide in ethanol (60%) VS* until the red colour changes to yellow. Continue shaking and neutralising until the full yellow colour of the indicator is permanent in the lower layer after shaking vigorously for 2 minutes and allowing to separate; the reaction is complete in about 15 minutes. This procedure gives an approximate value for the aldehyde content of the oil.

Repeat this procedure, using as the colour standard for the end point of the titration the titrated liquid of the first determination with the addition of 0.5 mL of 0.5M *potassium hydroxide in ethanol (60%) VS*. Calculate the content of aldehydes from the second determination, using the equivalent given in the monograph.

L. Oxidising Substances

(Ph. Eur. method 2.5.30)

Transfer 4.0 g to a glass-stoppered, 125 mL conical flask and add 50.0 mL of *water R*. Insert the stopper and swirl for 5 min. Transfer to a glass-stoppered 50 mL centrifuge tube and centrifuge. Transfer 30.0 mL of the clear supernatant to a glass-stoppered 125 mL conical flask. Add 1 mL of *glacial acetic acid R* and 0.5 g to 1.0 g of *potassium iodide R*. Insert the stopper, swirl, and allow to stand for 25 min to 30 min in the dark. Add 1 mL of *starch solution R* and titrate with *0.002 M sodium thiosulfate* until the starch-iodine colour disappears. Carry out a blank determination. Not more than 1.4 mL of *0.002 M sodium thiosulfate* is required (0.002 per cent, calculated as H_2O_2).

1 mL of *0.002 M sodium thiosulfate* is equivalent to 34 µg of oxidising substances, calculated as hydrogen peroxide.

M. Essential Oils

Fatty Oils and Resinified Essential Oils in Essential Oils

(Ph. Eur. method 2.8.7)

Allow 1 drop of the essential oil to fall onto filter paper. The drop evaporates completely within 24 h without leaving any translucent or greasy spot.

Foreign Esters in Essential Oils
(Ph. Eur. method 2.8.6)

Heat 1 mL of the essential oil for 2 min on a water-bath with 3.0 mL of a freshly prepared 100 g/L solution of *potassium hydroxide R* in *alcohol R*. No crystals are formed within 30 min, even after cooling.

Odour and Taste of Essential Oils
(Ph. Eur. method 2.8.8)

Mix 3 drops of the essential oil with 5 mL of *alcohol (90 per cent V/V) R* and stir in 10 g of powdered *sucrose R*. The odour and taste are similar to that of the plant or parts of the plant from which the essential oil has been obtained.

Residue on Evaporation of Essential Oils
(Ph. Eur. method 2.8.9)

The residue on evaporation of an essential oil is the percentage by mass of the oil which remains after evaporation on a water-bath under the conditions specified below.

Apparatus The apparatus (see Figure 2.8.9.-1) consists of:
- water-bath with a cover having holes of 70 mm diameter;
- evaporating dish of heat-resistant glass which is inert to the contents;
- desiccator.

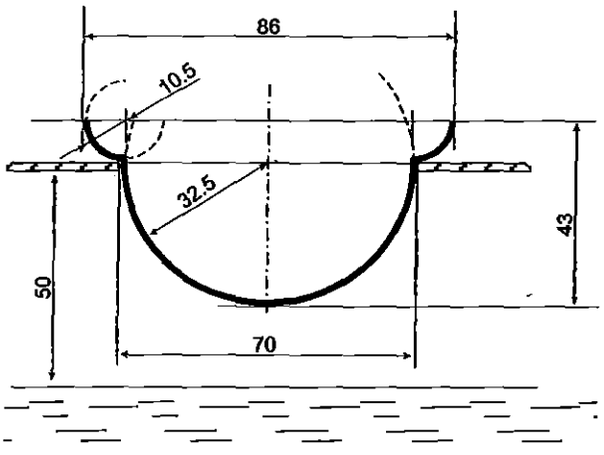

Figure 2.8.9.-1
Dimensions in millimetres

Method Weigh the evaporating dish after having heated it on the water-bath for 1 h and cooled it in the desiccator. Weigh into the evaporating dish 5.00 g of the essential oil, unless otherwise prescribed. Evaporate the oil by heating on a water-bath in a draught-free atmosphere for the prescribed time. Allow to cool in the desiccator and weigh.

During the test, the level of water in the bath is maintained about 50 mm beneath the level of the cover.

Solubility in Alcohol of Essential Oils
(Ph. Eur. method 2.8.10)

Place 1.0 mL of the essential oil in a 25 mL or 30 mL glass-stoppered cylinder. Place in a constant temperature device, maintained at a temperature of 20 ± 0.2 °C. Using a burette of at least 20 mL capacity, add the alcohol of the strength prescribed in the monograph by increments of 0.1 mL until solution is complete and then continue adding by increments of 0.5 mL to a total of 20 mL, shaking frequently and vigorously. Record the volume of alcohol added when a clear solution has been obtained and, if the solution becomes cloudy or opalescent before 20 mL of alcohol has been added, record the volume added when the cloudiness or opalescence appears and, where applicable, the volume added when the cloudiness or opalescence disappears.

If a clear solution has not been obtained when 20 mL of alcohol of the prescribed strength has been added, repeat the test using the next highest concentration of alcohol.

An essential oil is said to be "soluble in *n* volumes and more of alcohol of given strength *t*" when the clear solution in *n* volumes remains clear when compared with the undiluted oil after further addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be "soluble in *n* volumes of alcohol of given strength *t*, becoming cloudy when diluted" when the clear solution in *n* volumes becomes cloudy in n_1 volumes (n_1 less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be "soluble in *n* volumes of alcohol of given strength *t* with cloudiness between n_1 and n_2 volumes" when the clear solution in *n* volumes becomes cloudy in n_1 volumes (n_1 less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of n_2 volumes of alcohol and then becomes clear (n_2 less than 20).

An essential oil is said to be "soluble with opalescence" when the alcoholic solution shows a bluish tinge, similar to that of a standard of opalescence freshly prepared as follows: mix 0.5 mL of *silver nitrate solution R2* and 0.05 mL of *nitric acid R*; add 50 mL of a 12 mg/L solution of *sodium chloride R*; mix and allow to stand protected from light for 5 min.

Water in Essential Oils
(Ph. Eur. method 2.8.5)

Mix 10 drops of the essential oil with 1 mL of *carbon disulfide R*. The solution remains clear on standing.

N. Fixed Oils

Alkaline Impurities in Fatty Oils
(Ph. Eur. method 2.4.19)

In a test-tube mix 10 mL of recently distilled *acetone R* and 0.3 mL of *water R* and add 0.05 mL of a 0.4 g/L solution of *bromophenol blue R* in *alcohol R*. Neutralise the solution if necessary with *0.01 M hydrochloric acid* or *0.01 M sodium hydroxide*. Add 10 mL of the oil to be examined, shake and allow to stand. Not more than 0.1 mL of *0.01 M hydrochloric acid* is required to change the colour of the upper layer to yellow.

Identification of Fixed Oils by Thin-layer Chromatography
(Ph. Eur. method 2.3.2)

METHOD A

Thin-layer chromatography (*2.2.27*).

Test solution Unless otherwise prescribed, dissolve about 20 mg (1 drop) of the fatty oil in 3 mL of *methylene chloride R*.

Reference solution Dissolve about 20 mg (1 drop) of *maize oil R* in 3 mL of *methylene chloride R*.

Plate A suitable octadecylsilyl silica gel for high-performance thin-layer chromatography as the coating substance.

Mobile phase:
— *mobile phase A*: *ether R*;
— *mobile phase B*: *methylene chloride R*, *glacial acetic acid R*, *acetone R* (20:40:50 *V/V/V*).

Application 1 µL.

Development Twice over a path of 0.5 cm with mobile phase A, then twice over a path of 8 cm with mobile phase B.

Drying In air.

Detection Spray with a 100 g/L solution of *phosphomolybdic acid R* in *ethanol (96 per cent) R*. Heat the plate at 120 °C for about 3 min and examine in daylight.

The chromatogram obtained typically shows spots comparable to those in Figure 2.3.2.-1.

METHOD B

Thin-layer chromatography (*2.2.27*).

Test solution Unless otherwise prescribed, dissolve about 20 mg (1 drop) of the fatty oil in 3 mL of *methylene chloride R*.

Reference solution Dissolve about 20 mg (1 drop) of *maize oil R* in 3 mL of *methylene chloride R*.

Plate A suitable octadecylsilyl silica gel for high-performance thin-layer chromatography as the coating substance.

Mobile phase *methylene chloride R*, *glacial acetic acid R*, *acetone R* (20:40:50 *V/V/V*).

Application 1 µL as bands of 8 mm. A suitable automated apparatus may be used.

Development Over a path of 7 cm.

Drying In air.

Detection Treat with a 100 g/L solution of *phosphomolybdic acid R* in *ethanol (96 per cent) R*. Heat the plate at 120 °C for 3 min and examine in daylight.

The chromatogram obtained typically shows zones comparable to those in Figure 2.3.2.-2.

Test for Foreign Oils by Thin-layer Chromatography

(Ph. Eur. method 2.4.21)

Examine by thin-layer chromatography (*2.2.27*) using *kieselguhr G R* as the coating substance. Impregnate a plate by placing it in a chromatographic tank containing the necessary quantity of a mixture of 10 volumes of *liquid paraffin R* and 90 volumes of *light petroleum R* so that the plate dips about 5 mm beneath the surface of the liquid. When the impregnation mixture has risen by at least 12 cm from the lower edge of the plate, remove the plate and allow the solvent to evaporate for 5 min. Carry out the chromatography in the same direction as the impregnation.

Preparation of the mixture of fatty acids Heat 2 g of the oil with 30 mL of 0.5 M alcoholic potassium hydroxide under a reflux condenser for 45 min. Add 50 mL of *water R*, allow to cool, transfer to a separating funnel and extract with three quantities, each of 50 mL, of *ether R*. Discard the ether extracts, acidify the aqueous layer with *hydrochloric acid R* and extract with three quantities, each of 50 mL, of *ether R*. Combine the ether extracts and wash with three quantities, each of 10 mL, of *water R*; discard the washings, dry the ether over *anhydrous sodium sulfate R* and filter. Evaporate the ether on a water-bath. Use the residue to prepare the test solution. The fatty acids may also be obtained from the soap solution prepared during the determination of the unsaponifiable matter.

Test solution Dissolve 40 mg of the mixture of fatty acids obtained from the substance to be examined in 4 mL of *chloroform R*.

Reference solution Dissolve 40 mg of the mixture of fatty acids obtained from a mixture of 19 volumes of *maize oil R* and 1 volume of *rapeseed oil R* in 4 mL of *chloroform R*.

Apply to the plate 3 µL of each solution. Develop over a path of 8 cm using a mixture of 10 volumes of *water R* and 90 volumes of *glacial acetic acid R*. Dry the plate at 110 °C for 10 min. Allow to cool and, unless otherwise prescribed, place the plate in a chromatographic chamber, with a tightly fitting lid, that has previously been saturated with iodine vapour by placing *iodine R* in an evaporating dish at the bottom of the chamber. After some time brown or yellowish-brown spots become visible. Remove the plate and allow to stand for a few minutes. When the brown background colour has disappeared, spray with *starch solution R*. Blue spots appear which may become brown on drying and again become blue after spraying with *water R*. The chromatogram obtained with the test solution always shows a spot with an R_F of about 0.5 (oleic acid) and a spot with an R_F of about 0.65 (linoleic acid) corresponding to the spots in the chromatogram obtained with the reference solution. With some oils a spot with an R_F of about 0.75 may be present (linolenic acid). By comparison with the spot in the chromatogram obtained with the reference solution, verify the absence in the chromatogram obtained with the test solution of a spot with an R_F of about 0.25 (erucic acid).

Test for Foreign Oils by Gas Chromatography

(Ph. Eur. method 2.4.22)

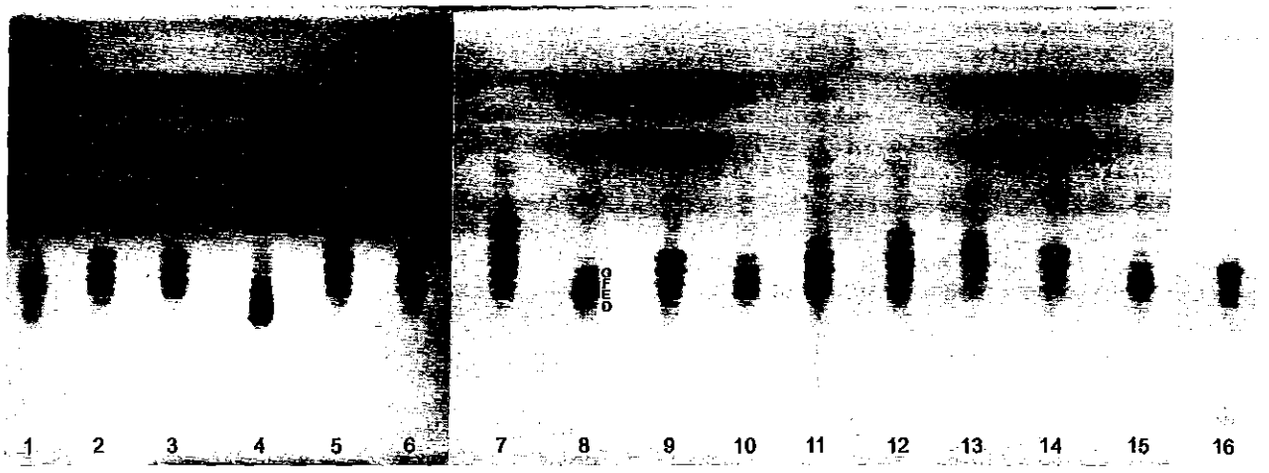
The test for foreign oils is carried out on the methyl esters of the fatty acids contained in the oil to be examined by gas chromatography (*2.2.28*).

METHOD A

This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, hydroperoxy-, cyclopropyl or cyclopropenyl group, or those that contain a large proportion of fatty acids of chain length less than 8 carbon atoms or to oils with an acid value greater than 2.0.

Test solution When prescribed in the monograph, dry the oil to be examined before the methylation step. Weigh 1.0 g of the oil into a 25 mL round-bottomed flask with a ground-glass neck fitted with a reflux condenser and a gas port into the flask. Add 10 mL of *anhydrous methanol R* and 0.2 mL of a 60 g/L solution of *potassium hydroxide R* in *methanol R*. Attach the reflux condenser, pass *nitrogen R* through the mixture at a rate of about 50 mL/min, shake and heat to boiling. When the solution is clear (usually after about 10 min), continue heating for a further 5 min. Cool the flask under running water and transfer the contents to a separating funnel. Rinse the flask with 5 mL of *heptane R* and transfer the rinsings to the separating funnel and shake. Add 10 mL of a 200 g/L solution of *sodium chloride R* and shake vigorously. Allow to separate and transfer the organic layer to a vial containing *anhydrous sodium sulfate R*. Allow to stand, then filter.

Reference solution (a) Prepare 0.50 g of the mixture of calibrating substances with the composition described in one of the 2.4.22 tables, as prescribed in the individual monograph (if the monograph does not mention a specific solution, use the composition described in Table 2.4.22.-1).



1. arachis oil
2. sesame oil
3. maize oil
4. rapeseed oil
5. soya-bean oil
6. rapeseed oil (erucic acid-free)
7. linseed oil
8. olive oil
9. sunflower oil
10. almond oil
11. wheat-germ oil
12. borage oil
13. evening primrose oil
14. safflower oil (type I)
15. safflower oil (type II)
16. hydrogenated arachis oil

Figure 2.3.2.-1. – *Chromatograms for the identification of fatty oils (method A)*

15. safflower oil (type II)
16. hydrogenated arachis oil

Figure 2.3.2.-2. – *Chromatograms for the identification of fatty oils (method B)*

Dissolve in *heptane R* and dilute to 50.0 mL with the same solvent.

Reference solution (b) Dilute 1.0 mL of reference solution (a) to 10.0 mL with *heptane R*.

Reference solution (c) Prepare 0.50 g of a mixture of fatty acid methyl esters that corresponds in composition to the mixture of fatty acids indicated in the monograph of the substance to be examined. Dissolve in *heptane R* and dilute to 50.0 mL with the same solvent. Commercially available mixtures of fatty acid methyl esters may also be used.

Column:
- *material*: fused silica, glass or quartz;
- *size*: *l* = 10-30 m, Ø = 0.2-0.8 mm;
- *stationary phase*: *macrogol 20 000 R* (film thickness 0.1-0.5 µm) or another suitable stationary phase.

Carrier gas *helium for chromatography R* or *hydrogen for chromatography R*.

Flow rate 1.3 mL/min (for a column Ø = 0.32 mm).

Split ratio 1:100 or less, according to the internal diameter of the column used (1:50 when Ø = 0.32 mm).

Temperature:
- *column*: in isothermal conditions, 160-200 °C, according to the length and type of column used (200 °C for a column 30 m long and coated with a layer of *macrogol 20 000 R*); if a linear temperature programming is necessary, raise the temperature of the column at a rate of 3 °C/min from 170 °C to 230 °C, for example;
- *injection port*: 250 °C;
- *detector*: 250 °C.

Detection Flame ionisation.

Injection 1 µL.

System suitability When using the mixture of calibrating substances in Table 2.4.22.-1 or Table 2.4.22.-3:
- *resolution*: minimum 1.8 between the peaks due to methyl oleate and methyl stearate in the chromatogram obtained with reference solution (a);
- *signal-to-noise ratio*: minimum 5 for the peak due to methyl myristate in the chromatogram obtained with reference solution (b);
- *number of theoretical plates*: minimum 30 000, calculated for the peak due to methyl stearate in the chromatogram obtained with reference solution (a).

System suitability When using the mixture of calibrating substances in Table 2.4.22.-2:
- *resolution*: minimum 4.0 between the peaks due to methyl caprylate and methyl decanoate in the chromatogram obtained with reference solution (a);
- *signal-to-noise ratio*: minimum 5 for the peak due to methyl caproate in the chromatogram obtained with reference solution (b);
- *number of theoretical plates*: minimum 15 000, calculated for the peak due to methyl decanoate in the chromatogram obtained with reference solution (a).

ASSESSMENT OF CHROMATOGRAMS

Avoid working conditions tending to give masked peaks (presence of constituents with small differences between retention times, for example linolenic acid and arachidic acid).

Qualitative analysis

Identify the peaks in the chromatogram obtained with reference solution (c) (isothermal operating conditions or linear temperature programming).

When using isothermal operating conditions, the peaks may also be identified by drawing calibration curves using the chromatogram obtained with reference solution (a) and the information given in Tables 2.4.22.-1, 2.4.22.-2 or 2.4.22.-3.

Table 2.4.22.-1. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

Mixture of the following substances	Composition (per cent *m/m*)
Methyl laurate R	5
Methyl myristate R	5
Methyl palmitate R	10
Methyl stearate R	20
Methyl arachidate R	40
Methyl oleate R	20

Table 2.4.22.-2. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

Mixture of the following substances	Composition (per cent *m/m*)
Methyl caproate R	10
Methyl caprylate R	10
Methyl decanoate R	20
Methyl laurate R	20
Methyl myristate R	40

Table 2.4.22.-3. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

Mixture of the following substances	Composition (per cent *m/m*)
Methyl myristate R	5
Methyl palmitate R	10
Methyl stearate R	15
Methyl arachidate R	20
Methyl oleate R	20
Methyl eicosenoate R	10
Methyl behenate R	10
Methyl lignocerate R	10

Measure the reduced retention time (t'_R) of each peak in the chromatogram obtained with reference solution (a). t'_R is the retention time measured from the solvent peak and not from the time of injection. Plot the straight line:

$$log_{10}(t'_R) = f(\text{equivalent chain length})$$

The logarithms of t'_R of unsaturated acids are situated on this line at points corresponding to non-integer values of carbon atoms known as 'equivalent chain lengths'; the equivalent chain length is the length of the theoretical saturated chain that would have the same t'_R as the fatty acid to be identified. For example, linoleic acid has the same t'_R as the theoretical saturated fatty acid having 18.8 carbon atoms.

Identify the peaks in the chromatogram obtained with the test solution by means of the straight line and the reduced retention times. Equivalent chain lengths are given in Table 2.4.22.-4.

Table 2.4.22.-4. – *Equivalent chain lengths (this value, which is to be calculated using calibration curves, is given as an example for a column of macrogol 20 000 R)*

Fatty acid	Equivalent chain length
Caproic acid	6.0
Caprylic acid	8.0
Capric acid	10.0
Lauric acid	12.0
Myristic acid	14.0
Palmitic acid	16.0
Palmitoleic acid	16.3
Margaric acid	17.0
Stearic acid	18.0
Oleic acid	18.3
Linoleic acid	18.8
Gamma-linolenic acid	19.0
Alpha-linolenic acid	19.2
Arachidic acid	20.0
Eicosenoic acid (gondoic acid)	20.2
Arachidonic acid	21.2
Behenic acid	22.0
Erucic acid	22.2
12-Oxostearic acid	22.7
Ricinoleic acid	23.9
12-Hydroxystearic acid	23.9
Lignoceric acid	24.0
Nervonic acid	24.2

Quantitative analysis

In general, the normalisation procedure is used in which the sum of the areas of the peaks in the chromatogram, except

that of the solvent, is set at 100 per cent. The content of a constituent is calculated by determining the area of the corresponding peak as a percentage of the sum of the areas of all the peaks. Disregard any peak with an area less than 0.05 per cent of the total area.

In certain cases, for example in the presence of fatty acids with 12 or less carbon atoms, correction factors can be prescribed in the individual monograph to convert peak areas in per cent *m/m*.

METHOD B

This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, hydroperoxy-, cyclopropyl or cyclopropenyl group or to oils with an acid value greater than 2.0.

Test solution Introduce 0.100 g of the substance to be examined into a 10 mL centrifuge tube with a screw cap. Dissolve with 1 mL of *heptane R* and 1 mL of *dimethyl carbonate R* and mix vigorously under gentle heating (50-60 °C). Add, while still warm, 1 mL of a 12 g/L solution of *sodium R* in *anhydrous methanol R*, prepared with the necessary precautions, and mix vigorously for about 5 min. Add 3 mL of *distilled water R* and mix vigorously for about 30 s. Centrifuge for 15 min at 1500 *g*. Inject 1 µL of the organic phase.

Reference solutions and assessment of chromatograms Where there is no specific prescription in the individual monograph, proceed as described under Method A.

Column:
- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *macrogol 20 000 R* (film thickness 0.25 µm).

Carrier gas *helium for chromatography R.*

Flow rate 0.9 mL/min.

Split ratio 1:100.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 15	100
	15 - 36	100 → 225
	36 - 61	225
Injection port		250
Detector		250

Detection Flame ionisation.

Injection 1 µL.

METHOD C

This method is not applicable to oils that contain glycerides of fatty acids with epoxy-, hydroepoxy-, hydroperoxy-, aldehyde, ketone, cyclopropyl and cyclopropenyl groups, and conjugated polyunsaturated and acetylenic compounds because of partial or complete destruction of these groups.

Test solution Dissolve 0.10 g of the substance to be examined in 2 mL of a 20 g/L solution of *sodium hydroxide R* in *methanol R* in a 25 mL conical flask and boil under a reflux condenser for 30 min. Add 2.0 mL of *boron trifluoride-methanol solution R* through the condenser and boil for 30 min. Add 4 mL of *heptane R* through the condenser and boil for 5 min. Cool and add 10.0 mL of *saturated sodium chloride solution R*, shake for about 15 s and add a quantity of *saturated sodium chloride solution R* such that the upper phase is brought into the neck of the flask. Collect 2 mL of the upper phase, wash with 3 quantities, each of 2 mL, of *water R* and dry over *anhydrous sodium sulfate R*.

Reference solutions, chromatographic procedure and assessment of chromatograms Where there is no specific prescription in the individual monograph, proceed as described under Method A.

O. Anisidine Value

(Ph. Eur. method 2.5.36)

The anisidine value is defined as 100 times the optical density measured in a 1 cm cell of a solution containing 1 g of the substance to be examined in 100 mL of a mixture of solvents and reagents according to the following method.

Carry out the operations as rapidly as possible, avoiding exposure to actinic light.

Test solution (a) Dissolve 0.500 g of the substance to be examined in *trimethylpentane R* and dilute to 25.0 mL with the same solvent.

Test solution (b) To 5.0 mL of test solution (a) add 1.0 mL of a 2.5 g/L solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

Reference solution To 5.0 mL of *trimethylpentane R* add 1.0 mL of a 2.5 g/L solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

Measure the absorbance (*2.2.25*) of test solution (a) at the maximum at 350 nm using *trimethylpentane R* as the compensation liquid. Measure the absorbance of test solution (b) at 350 nm exactly 10 min after its preparation, using the reference solution as the compensation liquid.

Calculate the anisidine value from the expression:

$$\frac{25 \times (1.2A_1 - A_2)}{m}$$

A_1 = absorbance of test solution (b) at 350 nm,
A_2 = absorbance of test solution (a) at 350 nm,
m = mass of the substance to be examined in test solution (a), in grams.

P. Oils Rich in Omega-3-acids

1. Composition of Fatty Acids

(Ph. Eur. method 2.4.29)

The assay may be used for quantitative determination of the eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA) and total omega-3-acids content in products from fish oil containing omega-3 acids in different concentrations. The method is applicable to triglycerides or ethyl esters. The former includes fish oils/fish-liver oils and omega-3-concentrates in triglyceride form. The results are expressed as triglycerides or ethyl esters, respectively.

EPA AND DHA

Gas chromatography (*2.2.28*). *Carry out the operations as rapidly as possible, avoiding exposure to actinic light, oxidising agents, oxidation catalysts (for example, copper and iron) and air.*

The assay is carried out on the methyl esters (after derivatisation of triglycerides - see step B below) or ethyl esters of (*all-Z*)-eicosa-5,8,11,14,17-pentaenoic acid (EPA; 20:5 n-3) and (*all-Z*)-docosa-4,7,10,13,16,19-hexaenoic acid (DHA; 22:6 n-3) in the substance to be examined.

Internal standard *methyl tricosanoate R.*

Test solutions Prepare all test solutions in duplicate.

Step A

— *Test solution (a).* Dissolve a quantity of the sample to be examined according to Table 2.4.29.-1 and 70.0 mg of the internal standard in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Gentle heating (up to 60 °C) may be applied to dissolve the internal standard. Ethyl esters are now ready for analysis. For triglycerides continue as described in step B.

Table 2.4.29.-1

Approximate sum EPA + DHA (per cent)	Mass of sample to be examined (g)
30 - 50	0.4 - 0.5
50 - 70	0.3
70 - 90	0.25

— *Test solution (b).* Dissolve a quantity of the sample to be examined according to Table 2.4.29.-1 in a 50 mg/mL solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Ethyl esters are now ready for analysis. For triglycerides continue as described in step B.

Step B

Introduce 2.0 mL of test solutions (a) and (b) obtained in step A into separate quartz tubes and evaporate the solvent with a gentle current of *nitrogen R.* Add 1.5 mL of a 20 g/L solution of *sodium hydroxide R* in *methanol R,* cover with *nitrogen R,* cap tightly with a polytetrafluoroethylene-lined cap, mix and heat on a water-bath for 7 min. Allow to cool. Add 2 mL of *boron trichloride-methanol solution R,* cover with *nitrogen R,* cap tightly, mix and heat on a water-bath for 30 min. Cool to 40-50 °C, add 1 mL of *trimethylpentane R,* cap and shake vigorously for at least 30 s. Immediately add 5 mL of a *saturated sodium chloride solution R,* cover with *nitrogen R,* cap and shake thoroughly for at least 15 s. Transfer the upper layer to a separate tube. Shake the methanol layer once more with 1 mL of *trimethylpentane R.* Wash the combined trimethylpentane extracts with 2 quantities, each of 1 mL, of *water R* and dry over *anhydrous sodium sulfate R.*

Reference solutions Prepare reference solutions (a_1) and (a_2) in duplicate; reference solution (c) only has to be prepared for triglycerides, and only if tetracos-15-enoic acid methyl ester is not clearly observed in the chromatogram obtained with test solution (a).

— *Reference solution (a_1).* Dissolve 70.0 mg of the internal standard and 90.0 mg of *eicosapentaenoic acid ethyl ester CRS* in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Gentle heating (up to 60 °C) may be applied to dissolve the internal standard.

— *Reference solution (a_2).* Dissolve 60.0 mg of *docosahexaenoic acid ethyl ester CRS* and 70.0 mg of the internal standard in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Gentle heating (up to 60 °C) may be applied to dissolve the internal standard.

For ethyl ester samples, reference solutions (a_1) and (a_2) are ready for analysis. For analysis of triglycerides, continue with step B in the same manner as for test solutions (a) and (b).

— *Reference solution (b).* Dissolve 0.300 g of *methyl arachidate R,* 0.300 g of *methyl behenate R,* 0.300 g of *methyl palmitate R* and 0.300 g of *methyl stearate R* in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution.

— *Reference solution (c).* Dissolve a mixture containing 55.0 mg of *docosahexaenoic acid methyl ester R* and 5.0 mg of *tetracos-15-enoic acid methyl ester R* in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution.

Column:

— *material:* fused silica;
— *dimensions:* l = at least 25 m, Ø = 0.25 mm;
— *stationary phase:* *macrogol 20 000 R* (film thickness 0.2 µm).

Carrier gas *hydrogen for chromatography R* or *helium for chromatography R.*

Flow rate 1 mL/min.

Split ratio 1:200, alternatively splitless with temperature control (sample solutions need to be diluted 1/200 with a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* before injection).

If necessary, adapt the split ratio and/or sample dilution to obtain a symmetry factor of 0.8-1.5 for the peaks due to the methyl or ethyl esters of eicosapentaenoic acid and docosahexaenoic acid, while at the same time observing that for test solution (b) any peaks due to the corresponding esters of linolenic acid (C18:3; n-3), stearidonic acid (C18:4; n-3), eicosatetraenoic acid (C20:4; n-3), heneicosapentaenoic acid (C21:5; n-3), and docosapentaenoic acid (C22:5; n-3) are clearly detectable. If both requirements are unachievable, then the clear detection of the corresponding esters mentioned above for test solution (b) takes precedence.

If necessary, adapt the split ratio and/or sample dilution to obtain a symmetry factor of 0.8-1.5 for the peaks due to the components of reference solution (b).

Temperature:

	Split injection		Splitless injection	
	Time (min)	Temperature (°C)	Time (min)	Temperature (°C)
Column	0 - 2	170	0 - 2	90
	2 - 25.7	170 → 240	2 - 4.7	90 → 170
	25.7 - 28	240	4.7 - 28	170 → 240
			28 - 30	240
Injection port		250		90 - 250*
Detector		270		270

*90 °C for on-column injection

Detection Flame ionisation.

Injection 1 µL.

System suitability:

— in the chromatogram obtained with reference solution (b), multiply the area of the peaks due to methyl palmitate, methyl stearate, methyl arachidate and methyl behenate by the corresponding response factors in Table 2.4.29.-2; normalise the corrected areas of the peaks of the fatty acid methyl esters to a sum of 100 per cent; the normalised area percentage of each fatty acid methyl ester is to be within ± 1.0 percentage units of the corresponding weight percentage;

Table 2.4.29.-2

Fatty acid methyl ester	Theoretical response factor
Methyl palmitate	1.049
Methyl stearate	1.029
Methyl arachidate	1.013
Methyl behenate	1.000

— *resolution*:
  — *ethyl esters*: minimum 1.2 between the peaks due to methyl tricosanoate and heneicosapentaenoic acid ethyl ester in the chromatogram obtained with test solution (a);
  — *triglycerides*: minimum 1.2 between the peaks due to docosahexaenoic acid methyl ester and tetracos-15-enoic acid methyl ester in the chromatogram obtained with test solution (a) or with reference solution (c);
— in the chromatogram obtained with test solution (a), the peaks due to methyl tricosanoate and any heneicosapentaenoic acid methyl ester present when compared with the chromatogram obtained with test solution (b) are clearly separated.

Calculate the percentage content of EPA and DHA using the following expression and taking into account the assigned value of the reference substances:

$$\frac{A_x \times m_1}{A_1 \times m_2} \times Rf \times C \times 100$$

Rf = response factor for EPA and DHA as given by the expression:

$$\frac{A_{x,3} \times m_{x,r}}{A_{x,r} \times m_{x,3}}$$

m_1 = mass of the internal standard in test solution (a), in milligrams;
m_2 = mass of the sample to be examined in test solution (a), in milligrams;
$m_{x,3}$ = mass of the internal standard in reference solution (a_1) (EPA determination), or in reference solution (a_2) (DHA determination), in milligrams;
$m_{x,r}$ = mass of *eicosapentaenoic acid ethyl ester CRS* in reference solution (a_1) or *docosahexaenoic acid ethyl ester CRS* in reference solution (a_2), in milligrams;
A_x = area of the peak due to eicosapentaenoic acid ester or docosahexaenoic acid ester in the chromatogram obtained with test solution (a);
$A_{x,r}$ = area of the peak due to eicosapentaenoic acid ester in the chromatogram obtained with reference solution (a_1) or docosahexaenoic acid ester in the chromatogram obtained with reference solution (a_2);
A_1 = area of the peak due to the internal standard in the chromatogram obtained with test solution (a);
$A_{x,3}$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (a_1) (EPA determination) or with reference solution (a_2) (DHA determination);
C = conversion factor between ethyl ester and triglycerides:

Ethyl esters: $C = 1.00$;
Triglycerides: $C = 0.954$ for EPA;
$C = 0.957$ for DHA.

TOTAL OMEGA-3 ACIDS

From the assay for EPA and DHA, calculate the percentage content of the total omega-3 acids using the following expression and identifying the peaks from the chromatograms:

$$EPA + DHA + \frac{A_{n-3}\,(EPA + DHA)}{A_{EPA} + A_{DHA}}$$

EPA = percentage content of EPA;
DHA = percentage content of DHA;
A_{n-3} = sum of the areas of the peaks due to linolenic acid (C18:3; n-3), stearidonic acid (C18:4; n-3), eicosatetraenoic acid (C20:4; n-3), heneicosapentaenoic acid (C21:5; n-3), and docosapentaenoic acid (C22:5; n-3) in the chromatogram obtained with test solution (b);
A_{EPA} = area of the peak due to EPA ester in the chromatogram obtained with test solution (b);
A_{DHA} = area of the peak due to DHA ester in the chromatogram obtained with test solution (b).

2. Total Cholesterol in Oils Rich in Omega-3-Acids

(Ph. Eur. method 2.4.32)

This method may be used for the quantitative determination of the sum of free and esterified cholesterol in products of fish oils rich in omega-3 acids (as ethyl esters or triglycerides).

Gas chromatography (*2.2.28*).

Internal standard stock solution Dissolve 0.15 g of *(5α)-cholestane R* in *heptane R* and dilute to 50.0 mL with the same solvent. The solution may be stored in a deep-freeze for up to 6 months.

Internal standard working solution. Prepare the solution immediately before use Dilute 1.0 mL of the internal standard stock solution to 10.0 mL with *heptane R*.

Cholesterol stock solution Dissolve 50.0 mg of *cholesterol R* in *heptane R* and dilute to 100.0 mL with the same solvent. The solution may be stored in a deep-freeze for up to 6 months.

Cholesterol working solution. Prepare the solution immediately before use Dilute 1.0 mL of the cholesterol stock solution to 10.0 mL with *heptane R*.

Cholesterol and α-tocopherol stock solution Dissolve 50.0 mg of *cholesterol R* and 50.0 mg of *α-tocopherol R* in *heptane R* and dilute to 100.0 mL with the same solvent. The solution may be stored at room temperature for up to 3 months.

Reference solution. Prepare the solution on the day of use Dilute 1.0 mL of the cholesterol and α-tocopherol stock solution to 100.0 mL with *heptane R*.

Calibration solutions See Table 2.4.32.-1. *Prepare the solutions on the day of use.* Dilute each solution to 20.0 mL with a 10 per cent *V/V* solution of *ethyl acetate R* in *heptane R*.

For high levels of cholesterol (3.0-20.0 mg/g), use all 5 calibration solutions.

For low levels of cholesterol (0.2-3.0 mg/g), use the following calibration solutions: 0.2 mg/g, 1.0 mg/g and 3.0 mg/g.

Test solution Weigh 0.100 g of the substance to be examined into a 15 mL quartz tube (for fish oils and cod-liver oils, shake the oil to be examined vigorously in a suitable container, allow to stand for 10-15 min and while maintaining the container upright, remove a sample from the middle layer of the oil for weighing). Add 1.0 mL of the internal standard working solution. Evaporate the solvent on a heating block at 50 °C under a gentle stream of *nitrogen R*. Add 0.5 mL of a 50 per cent *m/m* solution of *potassium hydroxide R* and 3.0 mL of *ethanol (96 per cent) R*. Fill the tube with *nitrogen R*, cap and homogenise. Heat on the heating block at 100 °C for 1 h. Cool for about 10 min, add 6.0 mL of *distilled water R* and homogenise. Condition a 20 mL solid phase extraction (SPE) column containing 1 g of *end-capped octadecylsilyl silica gel for chromatography R*

Table 2.4.32.-1. – *Preparation of calibration solutions*

Calibration solutions		Cholesterol stock solution (mL)	Cholesterol working solution (mL)	Internal standard working solution (mL)
Cholesterol concentration (mg/mL)	Cholesterol concentration (mg/g)[a]			
0.1	20.0	4.0		1.0
0.05	10.0	2.0		1.0
0.015	3.0	0.60		1.0
0.005	1.0		2.0	1.0
0.001	0.2		0.40	1.0

(a)Based on a sample weight of 0.100 g of the substance to be examined.

(particles with a diameter of 55 µm and a pore size of 7 nm) with 5 mL of a 50 per cent *V/V* solution of *ethanol (96 per cent) R* in *distilled water R*. Transfer 5.0 mL of the saponified sample to the SPE column ensuring that the column does not dry out. Wash the column with 5.0 mL of a 50 per cent *V/V* solution of *ethanol (96 per cent) R* in *distilled water R*. Elute the column using 20.0 mL of a 10 per cent *V/V* solution of *ethyl acetate R* in *heptane R*. Collect the eluate and use it as the test solution.

Column:
- *material*: fused silica;
- *size*: *l* = 15 m, Ø = 0.25 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

Carrier gas *helium for chromatography R.*

Pressure 48 kPa (corresponding to a flow rate of about 0.6 mL/min at 200 °C and about 0.4 mL/min at 330 °C).

Split ratio 1:5.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 1	200
	1 - 7.5	200 → 330
	7.5 - 10	330
Injection port		250
Detector		340

Prior to analysis, heat the column at 340 °C for at least 30 min using the indicated pressure.

Detection Flame ionisation.

Injection 1 µL.

Retention time (5α)-cholestane = about 7.5 min; cholesterol = about 9 min.

Plot the calibration curve. The x-axis represents the nominal concentration of cholesterol in milligrams per gram of the substance to be examined in each calibration solution. The y-axis represents the ratio of the area of the peak due to cholesterol to the area of the peak due to (5α)-cholestane in the chromatogram obtained with each calibration solution. Calculate the slope (*S*) and the intercept with the y-axis (*Y*).

System suitability:
- *resolution*: minimum 1.5 between the peaks due to cholesterol and α-tocopherol in the chromatogram obtained with the reference solution;
- the coefficient of determination (r^2) of the calibration curve is not less than 0.995.

Calculate the content of total cholesterol, expressed in milligrams of cholesterol per gram of substance to be examined, using the following expression:

$$\frac{\frac{A_1}{A_2} - Y}{m_1 \times S} \times 0.100$$

A_1 = area of the peak due to cholesterol in the chromatogram obtained with the test solution;
A_2 = area of the peak due to (5α)-cholestane in the chromatogram obtained with the test solution;
m_1 = mass of the substance to be examined in the test solution, in grams;
Y = intercept of the calibration curve with the y-axis;
S = slope of the calibration curve, in grams per milligram.

Q. Sterols in Fatty Oils

(Ph. Eur. method 2.4.23)

When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B must be validated.

METHOD A

Separation of the sterol fraction (TLC)

Prepare the unsaponifiable matter and then isolate the sterol fraction of the fatty oil by thin-layer chromatography (*2.2.27*), using a *TLC silica gel plate R* with a 0.2 mm to 0.5 mm layer.

Test solution (a) In a 150 mL flask fitted with a reflux condenser, place a volume of a 2 g/L solution of *betulin R* in *methylene chloride R* containing betulin corresponding to about 10 per cent of the sterol content of the sample used for the determination (e.g. in the case of olive oil add 500 µL, in the case of other vegetable oils add 1500 µL of the betulin solution). If the monograph requires the percentage content of the individual sterols in the sterol fraction, the addition of betulin may be omitted. Evaporate to dryness under a current of *nitrogen R*. Add 5.00 g (*m*) of the substance to be examined. Add 50 mL of *2 M alcoholic potassium hydroxide R* and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the flask to a separating funnel with 100 mL of *water R*. Shake the liquid carefully with 3 quantities, each of 100 mL, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 mL of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with several quantities, each of 40 mL, of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*. Distil off the ether with suitable precautions and add 6 mL of *acetone R* to the residue. Carefully remove the

solvent in a current of *nitrogen R*. Dry to constant mass at 100-105 °C. Allow to cool in a desiccator and weigh. Transfer the residue to a small test tube with *methylene chloride R*. Evaporate under a stream of *nitrogen R* to a volume of about 1 mL. Depending on the unsaponifiable content of the oil, adapt the final concentration of the solution to 25-50 mg/mL.

Test solution (b) Treat 5.00 g of *rapeseed oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 mL of *2 M alcoholic potassium hydroxide R*".

Test solution (c) Treat 5.00 g of *sunflower oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 mL of *2 M alcoholic potassium hydroxide R*".

Reference solution Dissolve 25 mg of *cholesterol R* and 10 mg of *betulin R* in 1 mL of *methylene chloride R*.

Use a separate plate for each test solution. Apply as a band of 10 mm, at 20 mm from the base and 10 mm from the left edge, 10 µL of the reference solution and as bands of 150 mm, at 20 mm from the base, 0.5 mL of test solutions (a), (b) or (c). Develop over a path of 17 cm using a mixture of 35 volumes of *ether R* and 65 volumes of *hexane R*. Dry the plates in a current of *nitrogen R*. Spray the plates with a 2 g/L solution of *dichlorofluorescein R* in *anhydrous ethanol R* and examine in ultraviolet light at 254 nm. The chromatogram obtained with the reference solution shows bands due to cholesterol and betulin. The chromatograms obtained with the test solutions show bands with similar R_F values due to sterols. From each of the chromatograms, remove an area of coating corresponding to the area occupied by the sterol bands and additionally the area of the zones 2-3 mm above and below the visible zones corresponding to the reference solution. Place separately in three 50 mL flasks. To each flask add 15 mL of *methylene chloride R* and heat under reflux with stirring, for 15 min. Filter each solution through a sintered-glass filter (40) (*2.1.2*) or suitable filter paper and wash each filter with 3 quantities, each of 15 mL, of *methylene chloride R*. Place the combined filtrate and washings from each filter separately in 3 flasks, evaporate under a stream of *nitrogen R* to 5-10 mL. Transfer to a small test tube and evaporate to dryness under a stream of *nitrogen R*.

Determination of the sterols (GC)

Gas chromatography (*2.2.28*). *Carry out the operations protected from humidity and prepare the solutions immediately before use.*

Test solution To the sterols separated from the substance to be examined by thin-layer chromatography add a freshly prepared mixture of 0.04 mL of *chlorotrimethylsilane R*, 0.1 mL of *hexamethyldisilazane R* and 0.5 mL of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

Reference solution (a) To 9 parts of the sterols separated from *rapeseed oil R* by thin-layer chromatography add 1 part of *cholesterol R*. To the mixture add a freshly prepared mixture of 0.04 mL of *chlorotrimethylsilane R*, 0.1 mL of *hexamethyldisilazane R* and 0.5 mL of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

Reference solution (b) To the sterols separated from *sunflower oil R* by thin-layer chromatography add a freshly prepared mixture of 0.04 mL of *chlorotrimethylsilane R*, 0.1 mL of *hexamethyldisilazane R* and 0.5 mL of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

Column:
- *material*: fused silica;
- *size*: *l* = 20-30 m, Ø = 0.25-0.32 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* or *cyanopropyl(7)phenyl(7)methyl(86)polysiloxane R* (film thickness 0.25 µm).

Carrier gas *hydrogen for chromatography R* or *helium for chromatography R*.

Linear velocity 30-50 cm/s (hydrogen) or 20-35 cm/s (helium).

Split ratio 1:50 (hydrogen) or 1:100 (helium).

Temperature:
- *column*: 260 °C;
- *injection port*: 280 °C;
- *detector*: 290 °C.

Detection Flame ionisation.

Injection 1 µL.

Identification of peaks The chromatogram obtained with reference solution (a) shows 4 principal peaks corresponding to cholesterol, brassicasterol, campesterol and β-sitosterol and the chromatogram obtained with reference solution (b) shows 4 principal peaks corresponding to campesterol, stigmasterol, β-sitosterol and Δ7-stigmastenol. The relative retentions of the sterols with reference to β-sitosterol (main peak) are given in Table 2.4.23.-1.

Table 2.4.23.-1. – *Relative retentions of sterols with reference to β-sitosterol for 2 different columns*

	Cyanopropyl (7)(phenyl) (7)(methyl)(86) polysiloxane	Phenyl(5)methyl (95)polysiloxane
Cholesterol	0.64	0.63
Brassicasterol	0.70	0.71
24-Methylenecholesterol	0.79	0.80
Campesterol	0.82	0.81
Campestanol	0.83	0.82
Stigmasterol	0.87	0.87
Δ7-Campesterol	0.93	0.92
Δ5,23-Stigmastadienol	0.95	0.95
Clerosterol	0.96	0.96
β-Sitosterol	1	1
Sitostanol	1.01	1.02
Δ5-Avenasterol	1.03	1.03
Δ5,24-Stigmastadienol	1.09	1.08
Δ7-Stigmastenol(1)	1.13	1.12
Δ7-Avenasterol	1.18	1.16
Betulin	1.4	1.4

(1) This sterol may also be referred to as Δ7-stigmasterol in literature.

The peak due to the internal standard (betulin) must be clearly separated from the peaks due to the sterols to be determined.

For the chromatogram obtained with the test solution, identify the peaks and calculate the percentage content of each sterol in the sterol fraction of the substance to be examined using the following expression:

$$\frac{A}{S} \times 100$$

A = area of the peak due to the component to be determined;
S = sum of the areas of the peaks due to the components indicated in Table 2.4.23.-1; disregard the peak due to betulin.

If required in the monograph, calculate the content of each sterol in milligrams per 100 grams of the substance to be examined using the following expression:

$$\frac{A \times m' \times 100}{A' \times m}$$

A = area of the peak due to the component to be determined;
A' = area of the peak due to betulin;
m = mass of the sample of the substance to be examined, in grams;
m' = mass of *bendin R* added, in milligrams.

METHOD B

Preparation of the unsaponifiable matter

Prepare the unsaponifiable matter according to the method stated in the test for unsaponifiable matter of the monograph on the substance to be examined. Failing this, prepare the unsaponifiable matter according to the method described in chapter *2.5.7. Unsaponifiable matter*. After the final neutralisation step, evaporate the ethanol, then add 6 mL of *acetone R* and evaporate the solvent. Dry the residue at 100-105 °C. It is not necessary to dry to constant mass.

Simultaneously prepare under the same conditions the unsaponifiable matter of *sunflower oil R*. This will in particular serve to locate the sterol fraction to be collected.

Separation of the sterol fraction (LC)

Liquid chromatography (*2.2.29*).

Test solution Take up the residue with 3 quantities, each of 4 mL, of the solvent used during the preparation of the unsaponifiable matter (generally *ether R* or *light petroleum R*) and transfer to a 15 mL tube. Evaporate to dryness under a current of *nitrogen R*. Dissolve the residue in a volume of mobile phase sufficient to obtain a solution with an approximate concentration of 40 mg/mL. Add a few drops of *2-propanol R1* to improve the solubility (3 drops are normally sufficient to ensure complete solubilisation). Filter through a membrane filter (nominal pore size 0.45 µm).

Reference solution Proceed as described for the test solution with the unsaponifiable matter obtained with *sunflower oil R*.

Precolumn:
— *size*: l = 5 mm, Ø = 4.6 mm;
— *stationary phase*: *silica gel for chromatography R* (5 µm) with a pore size of 6 nm.

Column:
— *size*: l = 0.25 m, Ø = 4.6 mm;
— *stationary phase*: *silica gel for chromatography R* (5 µm) with a pore size of 6 nm.

Mobile phase *2-propanol R1, hexane R* (1:99 *V/V*).

Flow rate 1 mL/min.

Detection Spectrophotometer at 210 nm.

Injection 50 µL.

Identification of the peaks due to sterols The sterol fraction elutes at the end of the chromatogram. Locate the fraction to be collected using the chromatogram obtained with the reference solution, which shows 2 principal peaks eluting approximately between 23 min and 32 min. Collect the fraction at the detector outlet in a 15 mL tube with a screw cap. Evaporate the solvent under a current of *nitrogen R*.

Determination of the sterols (GC)

Gas chromatography (*2.2.28*).

Test solution Dissolve the residue of the sterol fraction obtained with the test solution in the previous LC step in 0.2 mL of *anhydrous pyridine R* and 0.2 mL of a mixture of 1 volume of *chlorotrimethylsilane R* and 99 volumes of *N,O-bis(trimethylsilyl)trifluoroacetamide R*. Stopper the tube tightly and heat at 80 °C for 20 min. Allow to cool and use the liquid phase.

Reference solution Dissolve the residue of the sterol fraction obtained with the reference solution in the previous LC step in 0.2 mL of *anhydrous pyridine R* and 0.2 mL of a mixture of 1 volume of *chlorotrimethylsilane R* and 99 volumes of *N,O-bis(trimethylsilyl)trifluoroacetamide R*. Stopper the tube tightly and heat at 80 °C for 20 min. Allow to cool and use the liquid phase.

A standard of cholesterol (*cholesterol R*) may also be used, alone or as a mixture with the sterol fraction of sunflower oil. Proceed with derivatisation as described for the test solution.

Column:
— *material*: fused silica;
— *size*: l = 30 m, Ø = 0.25 mm;
— *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

Carrier gas *helium for chromatography R*.

Flow rate 2.6 mL/min.

Split ratio 1:25.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 38	260
	38 - 44	260 → 290
	44 - 49	290
Injection port		290
Detector		290

Detection Flame ionisation.

Injection 1-3 µL (depending on the expected amount of sterols in the substance to be examined).

Identification of peaks Use the chromatogram obtained with the reference solution to identify the peaks due to campesterol, stigmasterol, β-sitosterol and Δ7-stigmastenol. Identify the peaks due to the sterols in the chromatogram obtained with the test solution using the chromatogram obtained with the reference solution and the relative retentions with reference to β-sitosterol (main peak) given in Table 2.4.23.-1.

System suitability Reference solution:
— *resolution*: minimum 4.0 between the peaks due to campesterol and stigmasterol.

Calculate the percentage content of each sterol in the sterol fraction of the substance to be examined using the following expression:

$$\frac{A}{S} \times 100$$

A = area of the peak due to the component to be determined;
S = sum of the areas of the peaks due to the components indicated in Table 2.4.23.-1, except betulin.

Appendix XI

A. Total Solids

(No Ph. Eur. method)

The term 'total solids' is applied to the residue obtained when the prescribed amount of the preparation is dried to constant weight under the conditions specified below.

APPARATUS

A shallow, flat-bottomed, flanged dish, about 75 mm in diameter and about 25 mm deep, made of nickel or other suitable metal of high heat conductivity and low specific heat and which is not affected by boiling water. Suitable dishes are described in British Standard 1742:1951 (Methods for the chemical analysis of condensed milk).

METHOD

Place the quantity stated in the monograph in a tared dish, evaporate at as low a temperature as possible until the ethanol is removed and heat on a water-bath until the residue is apparently dry. Transfer to an oven operating without a fan and dry to constant weight at 105° unless otherwise stated in the monograph. It may be necessary, for residues of a hygroscopic nature, to use a dish provided with a well-fitting cover and to cool in a desiccator.

B1. Ethanol-soluble Extractive

(No Ph. Eur. method)

Macerate 5 g of the air-dried drug, coarsely powdered, with 100 mL of *ethanol* of the specified strength in a closed flask for 24 hours, shaking frequently during the first 6 hours and then allowing to stand for 18 hours. Filter rapidly, taking precautions against loss of ethanol, evaporate 20 mL of the filtrate to dryness in a tared, flat-bottomed, shallow dish and dry at 105° to constant weight. Calculate the percentage of ethanol-soluble extractive with reference to the air-dried drug.

B2. Water-soluble Extractive

(No Ph. Eur. method)

To 5 g of the powdered drug (710) add 200 mL of boiling *water*. Allow to stand for 10 minutes, shaking occasionally. Allow to cool, dilute to 200 mL with *water* and filter. Evaporate 20 mL of the filtrate to dryness on a water-bath. Dry the residue in an oven at 100° to 105° for 15 minutes.

C. Swelling Index

(Ph. Eur. method 2.8.4)

The swelling index is the volume in millilitres occupied by 1 gram of a drug, including any adhering mucilage, after it has swollen in an aqueous liquid for 4 h.

In a 25 mL ground-glass stoppered cylinder graduated over a height of 125 ± 5 mm in 0.5 mL divisions, place 1.0 g of the drug, whole or of the degree of comminution prescribed in the monograph. Unless otherwise prescribed, moisten the drug with 1.0 mL of *alcohol R*, add 25 mL of *water R* and close the cylinder. Shake vigorously every 10 min for 1 h. Allow to stand for 3 h. At 90 min after the beginning of the test, release any large volumes of liquid retained in the layer of the drug and any particles of the drug floating at the surface of the liquid by rotating the cylinder about a vertical axis. Measure the volume occupied by the drug, including any adhering mucilage. Carry out 3 tests at the same time.

The swelling index is given by the mean of the 3 tests.

D. Foreign Matter

(Ph. Eur. method 2.8.2)

Herbal drugs should be free from moulds, insects and other animal contamination.

Foreign matter is material consisting of any or all of the following:

1) *foreign organs*: matter coming from the source plant but not defined as the herbal drug;

2) *foreign elements*: matter not coming from the source plant and of either vegetable or mineral origin.

DRIED PLANTS

Sampling and sample preparation

Apply general chapter *2.8.20. Herbal drugs: sampling and sample preparation*.

Determination of foreign matter

Weigh 100-500 g of the sample, or the minimum quantity prescribed in the individual monograph, and spread it out in a thin layer. Examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter, weigh it and calculate the percentage present.

FRESH PLANTS

Where general chapter *2.8.20. Herbal drugs: sampling and sample preparation* cannot be applied, use one of the following methods, as appropriate: use method A when the test can be carried out on the whole batch; use method B when the test cannot be carried on the whole batch.

METHOD A

Sampling and sample preparation

Carry out the test on the whole batch.

Determination of foreign matter

Spread the batch out in a thin layer and examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter, weigh it and calculate the percentage present.

METHOD B

Sampling and sample preparation

If it is not possible to inspect the whole batch, proceed as follows.

Bulk sample Prepare the bulk sample as described in general chapter *2.8.20. Herbal drugs: sampling and sample preparation*.

Test sample Use the bulk sample or, where the bulk sample is greater than 1 kg, reduce it to a mass of 500-1000 g by a suitable method which retains the representative nature of the bulk sample.

Determination of foreign matter

Use the sample, or the minimum quantity prescribed in the individual monograph, and spread it out in a thin layer. Examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter, weigh it and calculate the percentage present.

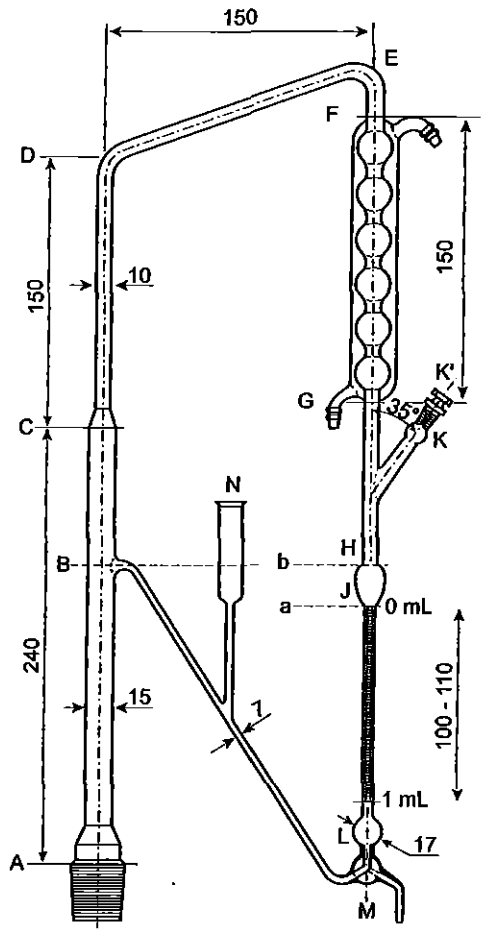

Figure 2.8.12.-1. – *Apparatus for the determination of essential oils in herbal drugs*

Dimensions in millimetres

E. Essential Oils in Herbal Drugs

(Ph. Eur. method 2.8.12)

PRINCIPLE

The determination of essential oils in herbal drugs is carried out by steam distillation in a special apparatus under the conditions described below. The distillate is collected in the graduated tube using the solvent prescribed in the monograph (usually *xylene R*, *trimethylpentane R* or *1,2,4-trimethylbenzene R*) to take up the essential oil; the aqueous phase is automatically returned to the distillation flask.

EQUIPMENT

The equipment typically consists of:

- a suitable round-bottomed flask with a short, ground-glass neck that has an internal diameter of about 29 mm at the wide end;
- a condenser assembly (see Figure 2.8.12.-1) that closely fits the flask, the different parts being fused into 1 piece and made of glass with a low coefficient of thermal expansion:
  - a vented stopper (*K'*) with an opening about 1 mm in diameter, and a tube (*K*), the wide end of which is made of ground-glass and has an internal diameter of 10 mm;
  - a pear-shaped swelling (*J*) with a capacity of 3 mL;
  - a tube (*JL*) graduated in 0.01 mL;
  - a bulb-shaped swelling (*L*) with a capacity of about 2 mL;
  - a 3-way tap (*M*);
  - a junction (*B*) situated at a level 20 mm higher than the uppermost graduation of tube *JL*;
- a suitable heating device, allowing fine temperature control;
- a vertical support with a horizontal ring covered with insulating material.

PROCEDURE

Use a thoroughly cleaned apparatus. Carry out the determination according to the nature of the herbal drug to be examined. Place the prescribed volume of distillation liquid in the flask, add a few pieces of porous porcelain and attach the condenser assembly. Introduce *water R* through the filling funnel (*N*) until it reaches level *B*. Remove the stopper (*K'*) and introduce the prescribed quantity of the solvent indicated in the monograph using a pipette with its tip placed at the bottom of tube *K*. Re-insert the stopper (*K'*) and ensure that the vent is unobstructed. Heat the liquid in the flask to boiling and adjust the distillation rate to 2-3 mL/min, unless otherwise prescribed.

Determination of the rate of distillation

During distillation, determine the rate of distillation by lowering the level of the water by means of tap *M* until the meniscus reaches the level of the lower mark (*a*) (see Figure 2.8.12.-2). Close tap *M* and measure the time taken for the liquid to reach the upper mark (*b*). Modify the heat to obtain the target distillation rate. If the distillation rate is still not within the prescribed range, repeat the operation. If the distillation conditions are not changed, it is sufficient to determine the distillation rate at regular intervals rather than before each test.

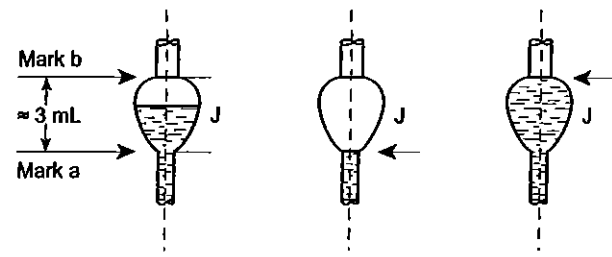

Figure 2.8.12.-2

Determination of the solvent volume after blank distillation

If using *xylene R* or *trimethylpentane R*, distil for 30 min. Ensure that tubes *BM* and *JM* are connected via tap *M* during distillation. Stop heating and wait at least 10 min before reading the volume of solvent in the graduated tube.

If using *1,2,4-trimethylbenzene R*, the 30 min blank distillation step is not necessary. Stop heating after adjusting the distillation rate and wait at least 10 min before reading the volume of solvent in the graduated tube.

Determination of the essential oil in the herbal drug

Introduce the prescribed quantity of the herbal drug into the flask and continue distillation as described above for the time and at the rate prescribed. Stop heating, read the volume of liquid collected in the graduated tube after 10 min and subtract the volume of the solvent previously noted. The difference represents the quantity of essential oil in the sample. Calculate the result in millilitres per kilogram of herbal drug.

Recovery of the mixture of solvent and essential oil
When the essential oil is to be used for other analytical purposes, the water-free mixture of solvent and essential oil may be recovered as follows: remove the stopper (*K'*) and introduce 0.1 mL of a 1 g/L solution of *sodium fluoresceinate R* and 0.5 mL of *water R*. Run the mixture of solvent and essential oil into the bulb-shaped swelling (*L*) by opening tap *M*, allow to stand for 5 min and lower the level of the mixture slowly until it just reaches the level of tap *M*. Open tap *M* clockwise so that the water flows out of the connecting tube (*BM*). Wash the tube with *acetone R* introduced through the filling funnel (*N*). Turn tap *M* anti-clockwise in order to recover the mixture of solvent and essential oil in an appropriate flask.

F. Continuous Extraction of Drugs

(No Ph. Eur. method)

Where the process of *maceration* or *percolation* is specified in a monograph, carry out the following procedures with any modification indicated in the monograph.

MACERATION
Place the solid materials with the whole of the menstruum in a closed vessel and allow to stand for 7 days, shaking occasionally. Strain, press the marc and mix the liquids obtained. Clarify by subsidence or filtration.

PERCOLATION
Moisten the solid materials with a sufficient quantity of the menstruum, allow to stand for 4 hours in a well-closed vessel, pack in a percolator and add sufficient of the menstruum to saturate the materials. When the liquid begins to drop from the percolator, close the outlet, add sufficient of the menstruum to leave a layer above the drug and allow to macerate for 24 hours. Allow percolation to proceed slowly until the percolate measures about three-quarters of the required volume. Press the marc, mix the expressed liquid with the percolate and add sufficient of the menstruum to produce the required volume. Clarify by subsidence or filtration.

Continuous extraction of a drug for the purpose of an assay consists of percolating the drug with the solvent stated in the monograph at a temperature approximately that of the boiling point of the solvent.

The apparatus described below, or any similar apparatus, may be used, provided that it permits the uniform percolation of the drug and the regular flow of the vapour of the solvent around the percolator.

The apparatus is shown in Fig. 11F–1. A is an outer tube of stout glass; the wider part is about 18 cm long and has an internal diameter of 4.8 to 5 cm; the lower end C is about 5 cm long and has an external diameter of about 1.6 cm. B is a straight glass tube open at both ends, about 9 cm long and with an external diameter of about 3.8 cm; over its lower, flanged end is tied firmly a piece of calico or other suitable material. D is a glass coil which supports the margin of the tube B and prevents it from resting in contact with the outer tube A. The lower end C of the outer tube A is fitted by a cork or ground-glass joint to the distillation flask E, in which a suitable quantity of the solvent has been placed. The drug to be extracted, previously moistened with the solvent or subjected to any preliminary treatment required, is introduced into the inner tube B, which is supported so that the percolate drops into the outer tube. A pad of absorbent cotton G is placed on the top of the drug, the inner tube is lowered into position and the outer tube connected by means of a suitable cork or ground-glass joint with the tube of a reflux condenser F. The flask is heated and the extraction continued as directed.

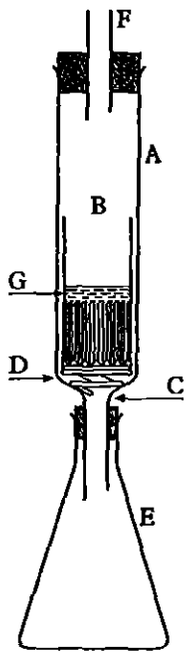

Fig. 11F–1 Apparatus for the Continuous Extraction of Drugs

G. Complete Extraction of Alkaloids

(No Ph. Eur. method)

Complete extraction is indicated by the following tests.

EXTRACTION WITH AN AQUEOUS OR ALCOHOLIC LIQUID
After extracting at least three times with the liquid, add to 0.1 to 0.2 mL of the next portion, after acidifying with 2M *hydrochloric acid* if necessary, 0.05 mL of *potassium tetraiodomercurate solution* or, for solanaceous alkaloids, 0.05 mL of *potassium iodobismuthate solution R1*.
No precipitate or turbidity is produced.

EXTRACTION WITH AN IMMISCIBLE SOLVENT
After extracting at least three times with the solvent, add to 1 to 2 mL of the next portion 1 to 2 mL of 0.1M *hydrochloric acid*, remove the organic solvent by evaporation, transfer the aqueous residue to a test tube and add 0.05 mL of *potassium tetraiodomercurate solution* or, for solanaceous alkaloids, 0.05 mL of *potassium iodobismuthate solution R1* or, for emetine, 0.05 mL of *iodinated potassium iodide solution*.
Not more than a very faint opalescence is produced.

CONTINUOUS EXTRACTION
After percolating for at least 2 hours, collect 1 to 2 mL of the effluent and carry out the procedure described under 'Extraction with an aqueous or alcoholic liquid' or 'Extraction with an immiscible solvent', as appropriate.

H. Stomata

(Ph. Eur. method 2.8.3)

STOMATA

There are several types of stomata (see Figure 2.8.3.-1), distinguished by the form and arrangement of the surrounding cells:

(1) The *anomocytic* (irregular-celled) type: the stoma is surrounded by a varying number of cells in no way differing from those of the epidermis generally,

(2) The *anisocytic* (unequal-celled) type: the stoma is usually surrounded by 3 subsidiary cells, of which one is markedly smaller than the others,

(3) The *diacytic* (cross-celled) type: the stoma is accompanied by 2 subsidiary cells, whose common wall is at right angles to the guard cells,

(4) The *paracytic* (parallel-celled) type: the stoma has on each side one or more subsidiary cells parallel to the long axis of the pore and guard cells.

STOMATAL INDEX

$$\text{Stomatal Index} = \frac{100 \times S}{E + S}$$

S = the number of stomata in a given area of leaf,
E = the number of epidermal cells (including trichomes) in the same area of leaf.

For each sample of leaf, make not fewer than 10 determinations and calculate the mean.

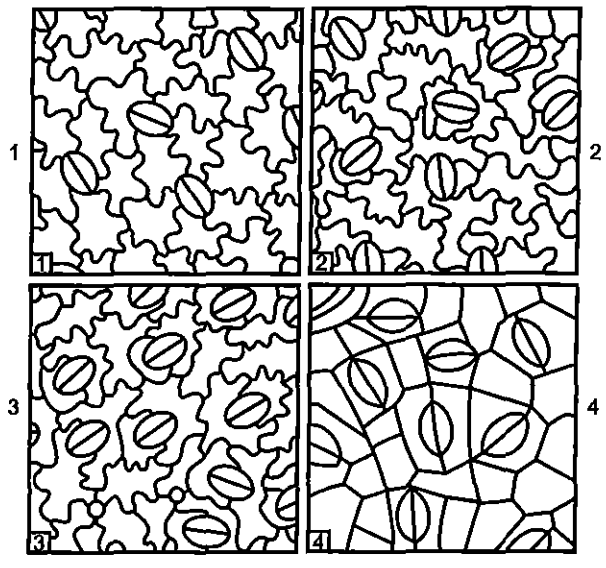

Figure 2.8.3.-1

J. Ash

Use Method I unless otherwise directed in the monograph.

Method I

(No Ph. Eur. method)

FOR HERBAL DRUGS

Incinerate 2 to 3 g of the ground drug in a tared platinum or silica dish at a temperature not exceeding 450° until free from carbon, cool and weigh. If a carbon-free ash cannot be obtained in this way, exhaust the charred mass with hot *water*, collect the residue on an ashless filter paper, incinerate the residue and filter paper, add the filtrate, evaporate to dryness and ignite at a temperature not exceeding 450°. Calculate the percentage of ash with reference to the air-dried drug.

FOR OTHER SUBSTANCES

Carry out the above method using 1 g, unless otherwise stated. Calculate the percentage of ash.

Method II

(Ph. Eur. method 2.4.16)

Heat a silica or platinum crucible to redness for 30 min, allow to cool in a desiccator and weigh. Unless otherwise prescribed, evenly distribute 1.00 g of the substance or the powdered herbal drug to be examined in the crucible. Dry at 100 °C to 105 °C for 1 h and ignite to constant mass in a muffle furnace at 600 °C ± 25 °C, allowing the crucible to cool in a desiccator after each ignition. Flames should not be produced at any time during the procedure. If after prolonged ignition the ash still contains black particles, take up with hot water, filter through an ashless filter paper and ignite the residue and the filter paper. Combine the filtrate with the ash, carefully evaporate to dryness and ignite to constant mass.

K. Acid-insoluble Ash

Use Method I unless otherwise directed in the monograph.

Method I

(No Ph. Eur. method)

Boil the *ash* for 5 minutes with 25 ml of 2M *hydrochloric acid*, collect the insoluble matter in a sintered-glass crucible or on an ashless filter paper, wash with hot *water* and ignite. Calculate the percentage of acid-insoluble ash with reference to the air-dried drug.

Method II

(Ph. Eur. method 2.8.1)

Ash insoluble in hydrochloric acid is the residue obtained after extracting the sulfated or total ash with hydrochloric acid, calculated with reference to 100 g of drug.

To the crucible containing the residue from the determination of sulfated or total ash, add 15 mL of *water R* and 10 mL of *hydrochloric acid R*, cover with a watch-glass, boil the mixture gently for 10 min and allow to cool. Filter through an ashless filter, wash the residue with hot *water R* until the filtrate is neutral, dry, ignite to dull redness, allow to cool in a desiccator and weigh. Reheat until the difference between 2 consecutive weighings is not more than 1 mg.

L. Pesticide Residues

(Ph. Eur. method 2.8.13)

Definition

For the purposes of the Pharmacopoeia, a pesticide is any substance or mixture of substances intended for preventing, destroying or controlling any pest, unwanted species of plants or animals causing harm during or otherwise interfering with the production, processing, storage, transport or marketing of herbal drugs. The item includes substances intended for use as growth-regulators, defoliants or desiccants and any substance applied to crops, either before or after harvest, to

protect the commodity from deterioration during storage and transport. Pesticide residues can be present and are controlled in herbal drugs and herbal drug preparations.

Limits

Unless otherwise indicated in the monograph, the herbal drug to be examined at least complies with the limits indicated in Table 2.8.13.-1. The limits applying to pesticides that are not listed in Table 2.8.13.-1 and whose presence is suspected for any reason comply with the limits (levels) cross-referred to by Regulation (EC) No. 396/2005, including annexes and successive updates. Limits for pesticides that are not listed in Table 2.8.13.-1 or in European Union texts are calculated using the following expression:

$$\frac{ADI \times M}{MDD_{HD} \times 100}$$

ADI = acceptable daily intake, as published by FAO-WHO, in milligrams per kilogram of body mass;
M = body mass in kilograms (60 kg);
MDD_{HD} = daily dose of the herbal drug, in kilograms.

The limits for pesticides in herbal drug preparations are calculated using the following expressions:

If $DER \leq 10$: $MRL_{HD} \times DER$

If $DER > 10$: $\frac{ADI \times M}{MDD_{HP} \times 100}$

MRL_{HD} = maximum residue limit of the pesticide in the herbal drug as given in Table 2.8.13.-1 or in EU texts or calculated using the expression mentioned above;
DER = drug/extract ratio, i.e. the ratio between the quantity of herbal drug used in the manufacture of a herbal drug preparation and the quantity of herbal drug preparation obtained;
MDD_{HP} = daily dose of the herbal drug preparation, in kilograms.

The competent authority may grant total or partial exemption from the test when the complete history (nature and quantity of the pesticides used, date of each treatment during cultivation and after the harvest) of the treatment of the batch is known and can be checked precisely according to good agricultural and collection practice (GACP).

Table 2.8.13.-1

Substance	Limit (mg/kg)
Acephate	0.1
Alachlor	0.05
Aldrin and dieldrin (sum of)	0.05
Azinphos-ethyl	0.1
Azinphos-methyl	1
Bromophos-ethyl	0.05
Bromophos-methyl	0.05

S-421	0.02
Tecnazene	0.05
Tetradifon	0.3
Vinclozolin	0.4

Sampling of herbal drugs

Sampling is done according to general chapter *2.8.20. Herbal drugs: sampling and sample preparation.*

Qualitative and quantitative analysis of pesticide residues

The analytical procedures used are validated (e.g. according to Document No. SANCO/10232/2006 or any subsequent

revisions of this document). In particular, they satisfy the following criteria:

- — the chosen method, especially the purification steps, is suitable for the combination pesticide residue/substance to be examined, and not susceptible to interference from co-extractives;
- — natural occurrence of some constituents is considered in the interpretation of results (e.g. disulfide from crucifers);
- — the concentration of test and reference solutions and the setting of the apparatus are such that the responses used for quantification of the pesticide residues are within the dynamic range of the detector; test solutions containing pesticide residues at a level outside the dynamic range, may be diluted within the calibration range, provided that the concentration of the matrix in the solution is adjusted in the case where the calibration solutions must be matrix-matched;
- — between 70 per cent to 110 per cent of each pesticide is recovered;
- — repeatability of the method: RSD is not greater than the values indicated in Table 2.8.13.-2;
- — reproducibility of the method: RSD is not greater than the values indicated in Table 2.8.13.-2.

Table 2.8.13.-2

Concentration range of the pesticide (mg/kg)	Repeatability (RSD) (per cent)	Reproducibility (RSD) (per cent)
0.001 - 0.01	30	60
> 0.01 - 0.1	20	40
> 0.1 - 1	15	30
> 1	10	20

M. Tannins in Herbal Drugs

(Ph. Eur. method 2.8.14)

Carry out all the extraction and dilution operations protected from light.

In the case of a herbal drug or a dry extract, to the stated amount of the powdered drug (180) (*2.9.12*) or the extract in a 250 mL round-bottomed flask add 150 mL of *water R*. Heat on a water-bath for 30 min. Cool under running water and transfer quantitatively to a 250 mL volumetric flask. Rinse the round-bottomed flask and collect the washings in the volumetric flask, then dilute to 250.0 mL with *water R*. Allow the solids to settle and filter the liquid through a filter paper 125 mm in diameter. Discard the first 50 mL of the filtrate.

In the case of a liquid extract or a tincture, dilute the stated amount of the liquid extract or tincture to 250.0 mL with *water R*. Filter the mixture through a filter paper 125 mm in diameter. Discard the first 50 mL of the filtrate.

Total polyphenols Dilute 5.0 mL of the filtrate to 25.0 mL with *water R*. Mix 2.0 mL of this solution with 1.0 mL of *phosphomolybdotungstic reagent R* and 10.0 mL of *water R* and dilute to 25.0 mL with a 290 g/L solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm (A_1), using *water R* as the compensation liquid.

Polyphenols not adsorbed by hide powder To 10.0 mL of the filtrate, add 0.10 g of *hide powder CRS* and shake vigorously for 60 min. Filter and dilute 5.0 mL of the filtrate to 25.0 mL with *water R*. Mix 2.0 mL of this solution with 1.0 mL of *phosphomolybdotungstic reagent R* and 10.0 mL of *water R* and dilute to 25.0 mL with a 290 g/L solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm (A_2), using *water R* as the compensation liquid.

Standard Dissolve immediately before use 50.0 mg of *pyrogallol R* in *water R* and dilute to 100.0 mL with the same solvent. Dilute 5.0 mL of the solution to 100.0 mL with *water R*. Mix 2.0 mL of this solution with 1.0 mL of *phosphomolybdotungstic reagent R* and 10.0 mL of *water R* and dilute to 25.0 mL with a 290 g/L solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm (A_3), using *water R* as the compensation liquid.

Calculate the percentage content of tannins expressed as pyrogallol from the expression:

$$\frac{62.5(A_1 - A_2)m_2}{A_3 \times m_1}$$

m_1 = mass of the sample to be examined, in grams;
m_2 = mass of pyrogallol, in grams.

N. Bitterness Value

(Ph. Eur. method 2.8.15)

The bitterness value is the reciprocal of the dilution of a compound, a liquid or an extract that still has a bitter taste. It is determined by comparison with quinine hydrochloride, the bitterness value of which is set at 200 000.

Determination of the correction factor

A taste panel comprising at least 6 persons is recommended. The mouth must be rinsed with *water R* before tasting.

To correct for individual differences in tasting bitterness amongst the panel members it is necessary to determine a correction factor for each panel member.

Stock solution Dissolve 0.100 g of *quinine hydrochloride R* in *water R* and dilute to 100.0 mL with the same solvent. Dilute 1.0 mL of this solution to 100.0 mL with *water R*.

Reference solutions Prepare a series of dilutions by placing in a first tube 3.6 mL of the stock solution and increasing the volume by 0.2 mL in each subsequent tube to a total of 5.8 mL; dilute the contents of each tube to 10.0 mL with *water R*.

Determine as follows the dilution with the lowest concentration that still has a bitter taste. Take 10.0 mL of the weakest solution into the mouth and pass it from side to side over the back of the tongue for 30 s. If the solution is not found to be bitter, spit it out and wait for 1 min. Rinse the mouth with *water R*. After 10 min, use the next dilution in order of increasing concentration.

Calculate the correction factor k for each panel member from the expression:

$$k = \frac{n}{5.00}$$

n = number of millilitres of the stock solution in the dilution of lowest concentration that is judged to be bitter.

Persons who are unable to taste any bitterness when using the reference solution prepared from 5.8 mL of stock solution have to be excluded from the panel.

Sample preparation

If necessary, reduce the sample to a powder (710) (*2.9.12*). To 1.0 g of sample add 100 mL of boiling *water R*. Heat on a water-bath for 30 min, stirring continuously. Allow to cool and dilute to 100 mL with *water R*. Shake vigorously and filter, discarding the first 2 mL of the filtrate. The filtrate is labelled C-1 and has a dilution factor (DF) of 100.

If liquids have to be examined, 1 mL of the liquid is diluted with a suitable solvent to 100 mL and designated C-1.

Determination of the bitterness value

Test solutions:
10.0 mL of C-1 is diluted with *water R* to 100 mL: C-2 (DF = 1000)
10.0 mL of C-2 is diluted with *water R* to 100 mL: C-3 (DF = 10 000)
20.0 mL of C-3 is diluted with *water R* to 100 mL: C-3A (DF = 50 000)
10.0 mL of C-3 is diluted with *water R* to 100 mL: C-4 (DF = 100 000)

Starting with dilution C-4 each panel member determines the dilution which still has a bitter taste. This solution is designated D. Note the DF of solution D is Y.

Starting with solution D prepare the following sequence of dilutions:

Solution D (mL)	1.2	1.5	2.0	3.0	6.0	8.0
water R (mL)	8.8	8.5	8.0	7.0	4.0	2.0

Determine the number of millilitres of solution D which, when diluted to 10.0 mL with *water R*, still has a bitter taste (X).

Calculate the bitterness value for each panel member from the expression:

$$\left(\frac{Y \times k}{X \times 0.1}\right)$$

Calculate the bitterness value of the sample to be examined as the average value for all panel members.

O. Foam Index

(Ph. Eur. method 2.8.24)

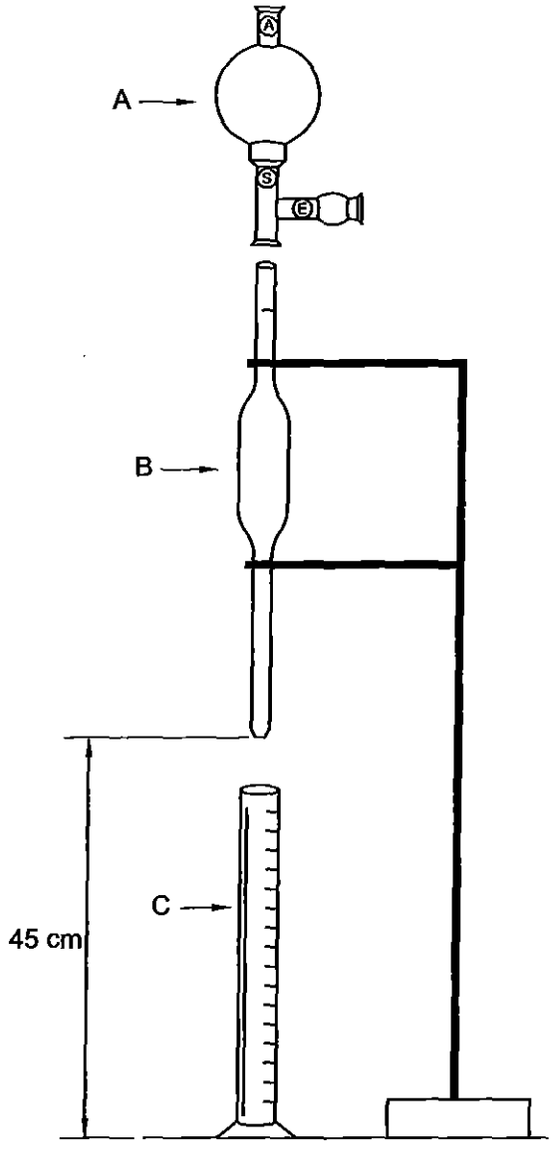
PRINCIPLE

The foam index is determined by measuring the height of the foam produced by the equivalent of 1 g of herbal drug or herbal drug preparation under the stated test conditions.

EQUIPMENT

The equipment (see Figure 2.8.24.-1) typically consists of:
— a pipette stand;
— a 50 mL class A pipette with a rubber filler bulb;
— a 250 mL glass measuring cylinder with 2 mL graduations and an internal diameter of 38 ± 3 mm.

Mount the pipette on its stand so that the tip will be located 45 cm from the base of the cylinder placed under it. Position the cylinder so that the pipette tip is aligned with its centre. Before performing the test, fill the pipette and cylinder with water to check that the liquid dispensed from the pipette runs into the centre of the measuring cylinder. Mark the location of the measuring cylinder.



A. rubber pipette filler
B. 50 mL class A pipette
C. 250 mL glass measuring cylinder with 2 mL graduations and an internal diameter of 38 ± 3 mm

Figure 2.8.24.-1. – *Apparatus suitable for measuring the foam index*

PROCEDURE

Preparation of the test solution

Introduce the quantity of powdered herbal drug (355) (*2.9.12*) or herbal drug preparation prescribed in the monograph into a 250 mL beaker. Add 50 mL of *distilled water R* and allow to stand for 30 min, mixing 3-5 times with a spatula during this period to disperse the powder without producing any foam. Rinse the spatula and the internal walls of the beaker with a further 50 mL of *distilled water R* to ensure that as much of the herbal drug or herbal drug preparation as possible is contained within the liquid. Allow to stand undisturbed for 30 min. Filter through a filter paper 125 mm in diameter. Use the filtrate as the test solution.

Method

Mount the pipette on the stand. Take up 50.0 mL of the test solution using the pipette. Rinse the measuring cylinder with *distilled water R* to wet its walls, then introduce the remaining

volume of test solution, taking care not to produce any foam. Position the measuring cylinder on its mark under the pipette. Open pipette filler valve E to allow the solution to run from the pipette into the measuring cylinder. Record the maximum height of the foam before it starts to collapse. Repeat the test twice, carefully rinsing the pipette and the measuring cylinder with *distilled water R* between tests.

Results

Determine the foam index (I_F) using the following equation:

$$I_F = \frac{H}{m}$$

H = height of the resulting foam, in centimetres;
m = mass of the herbal drug or herbal drug preparation used to prepare the test solution, in grams.

Record the average of 3 determinations as the result.

This result represents the height of the foam for a test solution with a theoretical concentration of 1 g in 100 mL.

P. Dry Residue of Extracts

(Ph. Eur. method 2.8.16)

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, introduce rapidly 2.00 g or 2.0 mL of the extract to be examined. Evaporate to dryness on a water-bath and dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage or in grams per litre.

Q. Loss on Drying of Extracts

(Ph. Eur. method 2.8.17)

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, weigh rapidly 0.50 g of the extract to be examined, finely powdered. Dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage.

R. Test for Aristolochic Acids in Herbal Drugs

Use Method R1 unless otherwise directed in the monograph.

R1. Test for Aristolochic Acids in Herbal Drugs

(Ph. Eur. method 2.8.21)

CAUTION: aristolochic acids are very toxic and carcinogenic. Perform manipulations in a fume cupboard whenever possible. Take particular precautions, such as use of a glove box, when the substance is in dry form because of its electrostatic properties and the tendency to disperse through the working areas.

Methods A and B are intended to be cross-referenced in monographs on herbal drugs that, according to chemotaxonomic knowledge, are expected to be free from aristolochic acids, but that may be subject to adulteration or substitution with plant material containing aristolochic acids. Methods A and B are intended to be used in the screening of herbal drugs for aristolochic acids at the stated limits and will usually be complemented by macroscopic and/or microscopic tests to exclude plant material containing aristolochic acids.

Method C will not be used in specific monographs but is provided as a method to confirm the presence of aristolochic acid I at levels equal to or greater than 2 ppm. It may be applied if chromatographic data suggests the presence of aristolochic acid I.

These methods are not designed for inclusion as assay methods in monographs on those drugs that produce aristolochic acids as secondary metabolites; for these, a more sensitive, validated method is required.

METHOD A: SCREENING TEST FOR ARISTOLOCHIC ACIDS

Thin-layer chromatography *(2.2.27)*.

Solvent mixture *anhydrous formic acid R, water R, methanol R* (1:9:40 *V/V/V*).

Test solution To 1.0 g of the powdered herbal drug (710) *(2.9.12)* add 10.0 mL of the solvent mixture, sonicate for 10 min and centrifuge.

Reference solution (a) Disperse an amount of *aristolochia HRS* corresponding to 0.10 mg of aristolochic acid I in 20.0 mL of the solvent mixture, sonicate for 10 min and centrifuge.

Reference solution (b) Dilute 1.0 mL of reference solution (a) to 25.0 mL with *methanol R*.

Plate *TLC silica gel F_{254} plate R* (2-10 µm).

Mobile phase *anhydrous formic acid R, water R, ethyl acetate R, toluene R* (3:3:30:60 *V/V/V/V*); use the upper layer.

Application 20 µL as bands of 8 mm.

Development Over a path of 6 cm.

Drying In a current of cold air for 5 min.

Detection Spray with a 100 g/L solution of *stannous chloride R* in *dilute hydrochloric acid R* until the plate is slightly wet, heat at 100 °C for 1 min and examine in ultraviolet light at 365 nm.

System suitability:

— the chromatogram obtained with reference solution (a) shows 2 greenish-blue zones due to aristolochic acids I and II between R_F = 0.35 and R_F = 0.55, which may not be completely separated;
— the chromatogram obtained with reference solution (b) shows at least 1 of these zones (corresponding to 2 ppm of aristolochic acid I).

Results In the chromatogram obtained with the test solution no zone is similar in position and fluorescence to any of the zones due to aristolochic acids in the chromatogram obtained with reference solution (a).

If the chromatogram obtained with the test solution shows any zones similar in position and fluorescence to any of the zones due to aristolochic acids I and II in the chromatogram obtained with reference solution (a), apply method B.

METHOD B: LIMIT TEST FOR ARISTOLOCHIC ACID I

Liquid chromatography *(2.2.29)*.

Solvent mixture *acetonitrile R, water R* (50:50 *V/V*).

Test solution Weigh 2.0 g of the powdered herbal drug (710) *(2.9.12)* into a 250 mL, brown, screw-cap bottle and add 100.0 mL of the solvent mixture. Stir for 30 min at about 300 r/min and filter through a membrane filter (nominal pore size 0.45 µm).

Reference solution (a) Dissolve the contents of a vial of *aristolochic acid I CRS* in the solvent mixture to obtain a concentration of 0.04 µg/mL of aristolochic acid I.

Reference solution (b) Dissolve the contents of a vial of *aristolochic acid for system suitability CRS* (containing aristolochic acids I and II) in the solvent mixture and dilute to 20.0 mL with the solvent mixture.

Column:
- *size:* l = 0.15 m, Ø = 2.1 mm;
- *stationary phase: octadecylsilyl silica gel for chromatography R* (3.5 µm);
- *temperature:* 40 °C.

Mobile phase:
- *mobile phase A: trifluoroacetic acid R, water R* (0.1:99.9 *V/V*);
- *mobile phase B: trifluoroacetic acid R, acetonitrile R* (0.1:99.9 *V/V*);

Time (min)	Mobile phase A (per cent *V/V*)	Mobile phase B (per cent *V/V*)
0 - 25	85 → 35	15 → 65
25 - 30	35 → 0	65 → 100
30 - 31	0 → 85	100 → 15

Flow rate 0.3 mL/min.

Detection Spectrophotometer at 390 nm.

Injection 25 µL.

System suitability:
- *resolution:* minimum 3.0 between the peaks due to aristolochic acids I and II in the chromatogram obtained with reference solution (b);
- *signal-to-noise ratio:* minimum 10 for the peak due to aristolochic acid I in the chromatogram obtained with reference solution (a).

Limit:
- the sample complies with the test if the chromatogram obtained with the test solution shows no peak with the same retention time as the peak due to aristolochic acid I in the chromatogram obtained with reference solution (a) (2 ppm).

METHOD C: CONFIRMATORY TEST FOR ARISTOLOCHIC ACID I

Liquid chromatography (*2.2.29*) coupled with mass spectrometry (*2.2.43*).

Solvent mixture *acetonitrile R, water R* (50:50 *V/V*).

Test solution Weigh 2.0 g of the powdered herbal drug (710) (*2.9.12*) into a 250 mL, brown, screw-cap bottle and add 100.0 mL of the solvent mixture. Sonicate for 30 min and filter through a membrane filter (nominal pore size 0.45 µm).

Reference solution (a) Dissolve the contents of a vial of *aristolochic acid I CRS* in the solvent mixture to obtain a concentration of 0.04 µg/mL of aristolochic acid I.

Reference solution (b) Prepare a solution according to the instructions supplied with *aristolochic acid I CRS* to obtain a concentration of 0.45 µg of aristolochic acid I in 10.0 mL of the test solution.

Column:
- *size:* l = 0.15 m, Ø = 2.1 mm;
- *stationary phase: octadecylsilyl silica gel for chromatography R* (3.5 µm);
- *temperature:* 40 °C.

Mobile phase:
- *mobile phase A: anhydrous formic acid R*, 1 g/L solution of *ammonium acetate R* in *water R* (0.1:99.9 *V/V*);
- *mobile phase B: anhydrous formic acid R*, 1 g/L solution of *ammonium acetate R* in *methanol R* (0.1:99.9 *V/V*);

Time (min)	Mobile phase A (per cent *V/V*)	Mobile phase B (per cent *V/V*)
0 - 15	70 → 0	30 → 100
15 - 16	0	100
16 - 17	0 → 70	100 → 30

Flow rate 0.4 mL/min.

Injection 20 µL; inject reference solution (a) twice, the test solution twice, reference solution (a) twice, then reference solution (b) twice.

Detection Mass detector as described below under A or B. Adjust the flow rate, the temperature and the detector settings so as to comply with the system suitability criterion.

A. Ion-trap mass spectrometer equipped with an electrospray ionisation (ESI) interface and MS^n analyser.

Set the mass spectrometer parameters for the MS^3 mode as follows:

Mode	Parent (*m/z*)	Isolation width (*m/z*)	Relative collision energy (per cent)
MS^2	359 $[M + NH_4]^+$	2.0	30
MS^3	298	2.0	35

- full scan of product ions: from *m/z* 80 to *m/z* 370;
- product ions to be monitored: *m/z* 252, *m/z* 268 and *m/z* 281.

System suitability:
- *signal-to-noise ratio:* minimum 100 for the monitored product ions in the chromatogram obtained with reference solution (a);
- *matrix interference test:* the average of the 2 ratios of reference solution (b) is inside the ± 40 per cent interval of the average of the 2 ratios of reference solution (a); otherwise it is necessary to adjust the detector settings.

Results Evaluate the average ratios (252/268 and 281/268) of the relative intensity of the 3 product ions of aristolochic acid I in the test solution; evaluate the average of the 2 ratios of the signals at the retention time of aristolochic acid I in reference solution (a); if the average of the 2 ratios of the test solution is within the ± 40 per cent interval of the average of the 2 ratios of reference solution (a), aristolochic acid I is present in the test solution.

B. Triple-quadrupole mass spectrometer equipped with an ESI interface and MS^n analyser.

Set the mass spectrometer parameters for the MS^2 mode as follows:
- precursor ion: *m/z* 359 $[M + NH_4]^+$;
- product ions to be monitored: *m/z* 265, *m/z* 281 and *m/z* 296.

System suitability:
- *signal-to-noise ratio:* minimum 100 for the monitored product ions in the chromatogram obtained with reference solution (a);
- *matrix interference test:* the average of the 2 ratios of reference solution (b) is inside the ± 40 per cent

interval of the average of the 2 ratios of reference solution (a); otherwise it is necessary to adjust the detector settings.

Results Evaluate the average ratios (265/281 and 296/281) of the relative intensity of the 3 product ions of aristolochic acid I in the test solution; evaluate the average of the 2 ratios of the signals at the retention time of aristolochic acid I in reference solution (a); if the average of the 2 ratios of the test solution is within the ± 40 per cent interval of the average of the 2 ratios of reference solution (a), aristolochic acid I is present in the test solution.

R2. Test for Aristolochic Acids I and II in Herbal Drugs

(No Ph. Eur. Method)

CAUTION *Aristolochic acids have been shown to be highly toxic and carcinogenic. Extraordinary care should be taken in any procedure in which they are used.*

In line with the prohibition of the use of *Aristolochia* species in unlicensed herbal medicines in the United Kingdom, a test for absence of aristolochic acids I and II in herbal drugs has been included in the British Pharmacopoeia. The limit of detection has been shown to be 0.00078 mg/mL (approximately 1 ppm of aristolochic acids I and II). It is advised that the limit of detection for the system-in-use is determined by the analyst. Aristolochic acids I and II are not confined to the genus *Aristolochia*. The acids are also reported as present in certain species of *Asarum*.

Sample preparation

Unless otherwise specified in the monograph, weigh 2 g of the ground herbal drug into a centrifuge tube. Add 10 mL of 0.1M *sodium hydroxide*, shake for at least 2 hours and centrifuge the mixture for 10 minutes at approximately 4000 revolutions per minute. Filter the supernatant layer if visible particles remain in the suspension. Pass a 1.0 mL portion of the sample solution with the aid of vacuum through a solid-phase extraction column of 1 mL capacity and containing 30 mg of *divinylbenzene and vinylpyrrolidone copolymer for chromatography* (30 µm) (Waters Oasis HLB, 30 mg/mL or Phenomenex StrataX, 30 mg/mL is suitable) previously washed with 1 mL of *methanol*, followed by 1 mL of *water*. Wash the column with 1 mL of 0.1M *sodium hydroxide* followed by 1 mL of a mixture containing 2 volumes of *glacial acetic acid*, 28 volumes of *water* and 70 volumes of *methanol*. Elute the sample with 0.25 mL of a mixture containing 98% of *methanol* and 2% of *concentrated ammonia*. Evaporate the extract to dryness at 40° under a stream of *nitrogen* and dissolve in 0.25 mL of *methanol*. If a larger sample volume is required then a larger capacity solid-phase extraction column may be used.

Use this as solution (1) for the identification method described below.

Identification

Carry out the method for *liquid chromatography*, Appendix III D, using the following solutions. Prepare solution (1) as described above under Sample preparation. Solution (2) contains 0.01% w/v of *aristolochic acid BPCRS* in *methanol*.

The chromatographic procedure may be carried out using (a) a stainless steel column (25 cm × 4.6 mm) packed with *base-deactivated octadecylsilyl silica gel for chromatography* (4 µm) (Genesis C18 is suitable) maintaining the column temperature at 30°, (b) a mixture of 45 volumes of 0.1% v/v of *orthophosphoric acid* and 55 volumes of *acetonitrile* as the mobile phase with a flow rate of 1.3 mL per minute and (c) a detection wavelength of 225 nm. The identity of any peaks suspected to be due to arisotolochic acids I and II may be clarified by use of the UV spectrum recorded with a diode array detector.

Inject 10 µL of solution (2) and allow the chromatography to proceed for 10 minutes. The test is not valid unless the *resolution factor* between the peaks corresponding to aristolochic acid II (retention time about 6 minutes) and aristolochic acid I (retention time about 7 minutes) is at least 3.0. Inject solution (2) six times. The relative standard deviation of the areas of the peaks is at most 1.5%.

Inject 10 µL of solution (1) and allow the chromatography to proceed for 30 minutes. In the chromatogram obtained with solution (1) the peaks due to aristolochic acid I and aristolochic acid II are absent.

S. Determination of Mycotoxins in Herbal Drugs

1. Determination of Aflatoxin B_1 in Herbal Drugs

(Ph. Eur. method 2.8.18)

CAUTION: aflatoxins are very toxic and carcinogenic. Perform manipulations in a fume cupboard whenever possible. Take particular precautions, such as use of a glove box, when toxins are in dry form because of their electrostatic properties and the tendency to disperse through the working areas. Decontamination procedures for laboratory wastes of aflatoxins were developed by the International Agency for Research on Cancer (IARC).

Aflatoxins are naturally occurring mycotoxins produced mainly by *Aspergillus flavus* and *Aspergillus parasiticus*. These fungi are common and widespread in nature and are most often found when certain grains are grown under conditions of stress such as drought. The mould occurs in soil, decaying vegetation, hay, and grains undergoing microbial spoilage, and invades all types of organic substrates whenever and wherever the conditions are favourable for its growth. Favourable conditions include high moisture content and high temperature. At least 13 different types of aflatoxin are produced in nature and most of these are known to be highly toxic and carcinogenic. Aflatoxin B_1 is considered the most toxic. Herbal drugs that are subject to contamination by aflatoxins are tested by a validated method.

Unless otherwise indicated in the monograph, herbal drugs contain not more than 2 µg/kg of aflatoxin B_1.

The competent authority may also require compliance with a limit of 4 µg/kg for the sum of aflatoxins B_1, B_2, G_1 and G_2.

The method described below is cited as an example of a method that has been shown to be suitable for devil's claw root, ginger and senna pods. Its suitability for other herbal drugs must be demonstrated or another validated method used.

METHOD

Liquid chromatography (*2.2.29*).

Aflatoxins are subject to light degradation. Carry out the determination protected from daylight by using UV-absorbing foil on windows in combination with subdued light, or curtains or blinds in combination with artificial light (fluorescent tubes are acceptable). Protect aflatoxin-containing solutions from daylight.

Rinse glassware before use with a 10 per cent *V/V* solution of *sulfuric acid R* and then rinse carefully with *distilled water R* until no more acid is present.

Test solution Use an immunoaffinity column containing antibodies against aflatoxin B_1 with a capacity of not less than 100 ng of aflatoxin B_1 and which gives a recovery of not less than 80 per cent when a solution of 5 ng of aflatoxin B_1 in a mixture of 12.5 mL of *methanol R* and 87.5 mL of *water R* is passed through. Allow the immunoaffinity column to reach room temperature. To 5.00 g of the powdered drug (500) (*2.9.12*) add 100 mL of a mixture of 30 volumes of *water R* and 70 volumes of *methanol R* and extract by sonication for 30 min. Filter through folded filter paper. Pipette 10.0 mL of the clear filtrate into a 150 mL conical flask. Add 70 mL of *water R*. Pass 40 mL through the immunoaffinity column at a flow rate of 3 mL/min (not exceeding 5 mL/min). Wash the column with 2 volumes, each of 10 mL, of *water R* at a flow rate not exceeding 5 mL/min and dry by applying a slight vacuum for 5-10 s or by passing air through the immunoaffinity column by means of a syringe for 10 s. Apply 0.5 mL of *methanol R* to the column and allow to pass through by gravity. Collect the eluate in a 5 mL volumetric flask. After 1 min, apply a 2nd portion of 0.5 mL of *methanol R*. After a further 1 min, apply a 3rd portion of 0.5 mL of *methanol R*. Collect most of the applied elution solvent by pressing air through or applying vacuum to the column. Dilute to 5 mL with *water R* and shake well. If the solution is clear it can be used directly for analysis. Otherwise, pass it through a disposable filter unit prior to injection. Use a disposable filter unit (e.g. 0.45 µm pore size polytetrafluoroethylene filter) that has been shown not to cause loss of aflatoxin by retention.

Aflatoxin B_1 primary stock solution Dissolve *aflatoxin B_1 R* in a mixture of 2 volumes of *acetonitrile R* and 98 volumes of *toluene R* to give a 10 µg/mL solution. To determine the exact concentration of aflatoxin B_1 in the stock solution, record the absorption curve (*2.2.25*) between 330 nm and 370 nm in quartz cells.

Calculate the aflatoxin B_1 mass concentration, in micrograms per millilitre, using the following expression:

$$\frac{A \times M \times 100}{\varepsilon \times l}$$

A	=	absorbance determined at the maximum of the absorption curve;
M	=	molar mass of aflatoxin B_1 (312 g/mol);
ε	=	molar absorptivity of aflatoxin B_1 in the toluene-acetonitrile mixture (1930 m^2/mol);
l	=	optical path length of the cell (1 cm).

Aflatoxin B_1 secondary stock solution Prepare a secondary stock solution containing 100 ng/mL aflatoxin B_1 by diluting aflatoxin B_1 primary stock solution with a mixture of 2 volumes of *acetonitrile R* and 98 volumes of *toluene R*. Wrap the flask tightly in aluminium foil and store it below 4 °C. Before use, do not remove the aluminium foil until the contents have reached room temperature. If the solution has to be stored for a long period (for example, 1 month), weigh the flask and record the mass before and after each use of the solution.

Aflatoxin B_1 standard solutions Place the volumes of aflatoxin secondary stock solution indicated in Table 2.8.18.-1 in separate 250 mL volumetric flasks. Pass a stream of nitrogen through at room temperature until the solvent has just evaporated. To each flask, add 75 mL of *methanol R*, allow the aflatoxin B_1 to dissolve and dilute to 250 mL with *water R*.

Table 2.8.18.-1. – *Aflatoxin B_1 standard solutions*

Standard solution	Volume of secondary stock solution (µL)	Final concentration of standard solution (ng/mL)
1	125	0.05
2	250	0.1
3	500	0.2
4	750	0.3
5	1000	0.4

Calibration curve Prepare the calibration curve using aflatoxin B_1 standard solutions 1 to 5, which cover a range equivalent to 1-8 µg/kg of aflatoxin B_1 in the herbal drug. Check the plot for linearity. If the content of aflatoxin B_1 in the sample to be examined is outside of the calibration range, the test solution must be diluted to an aflatoxin content that is appropriate for the established calibration curve.

Column:
- *size: l* = 0.25 m, Ø = 4.6 mm;
- *stationary phase: octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase:
- *mobile phase A* (for post-column derivatisation with photochemical reactor or pyridinium bromide): *acetonitrile R, methanol R, water R* (2:3:6 *V/V/V*);
- *mobile phase B* (for post-column derivatisation with electrochemically derived bromine): add 0.12 g of *potassium bromide R* and 350 µL of dilute nitric acid R1 per litre of mobile phase A.

Flow rate 1 mL/min.

Detection Fluorescence detector with a 360 nm excitation filter and a 420 nm cut-off emission filter, or equivalent. Recommended settings for adjustable detectors are 365 nm (excitation wavelength) and 435 nm (emission wavelength).

Injection 500 µL.

Post-column derivatisation with pyridinium hydrobromide perbromide (PBPB):
- pulseless pump;
- T-piece with zero dead volume;
- polytetrafluoroethylene reaction tube, l = 0.45 m, Ø = 0.5 mm;
- mobile phase A;
- post-column derivatisation reagent: dissolve 50 mg of *pyridinium hydrobromide perbromide R* in 1000 mL of *water R* (store protected from light and use within 4 days);
- flow rate of the derivatisation reagent: 0.4 mL/min.

Post-column derivatisation with photochemical reactor (PHRED)
- reactor unit with one 254 nm low pressure mercury UV bulb (minimum 8 W);
- polished support plate;
- knitted reactor coil: polytetrafluoroethylene tubing knitted tightly around the UV bulb, l = 25 m, Ø = 0.25 mm, nominal void volume 1.25 mL;
- exposure time: 2 min;
- mobile phase A.

Post-column derivatisation with electrochemically generated bromine (KOBRA):
- KOBRA-cell: electrochemical cell that generates a reactive form of bromine for derivatisation of aflatoxins, resulting in enhanced fluorescence; available from various commercial suppliers;
- Derivation direct-current supply in series with the KOBRA-cell, providing a constant current of about 100 µA;

— polytetrafluoroethylene reaction tube, l = 0.12 m, Ø = 0.25 mm;
— mobile phase B.

Elution order Aflatoxin G_2, aflatoxin G_1, aflatoxin B_2, aflatoxin B_1.

Calculation Calculate the calibration curve $y = ax + b$, with aflatoxin B_1 concentration (ng/mL) on the x-axis and the signal (S) on the y-axis. The aflatoxin B_1 concentration (C) in a measured solution is equal to $\frac{S-b}{a}$.

Calculate the aflatoxin B_1 content of the herbal drug, in nanograms per gram, using the following expression:

$$\frac{V_1 \times V_2 \times C}{m \times V_i}$$

m	=	mass of the herbal drug taken for analysis, in grams;
V_1	=	volume of the solvent used for extraction, in millilitres;
V_i	=	aliquot taken for immunoaffinity clean-up, in millilitres;
V_2	=	final volume of solution after elution from the immunoaffinity column and dilution, in millilitres;
C	=	measured aflatoxin B_1 concentration of the test solution, in nanograms per millilitre.

The presence of aflatoxin B_1 may be confirmed by recording the chromatogram without post-column derivatisation, which leads to a large decrease (greater than 10-fold) in the response due to aflatoxin B_1.

2. Determination of Ochratoxin A in Herbal Drugs

(Ph. Eur. method 2.8.22)

CAUTION: ochratoxin A is nephrotoxic and nephrocarcinogenic. Perform manipulations in a fume cupboard. Take particular precautions, such as use of a glove box, when toxins are in dry form because of their electrostatic properties and the tendency to disperse through the working areas. Decontamination procedures for laboratory glassware containing ochratoxin A are necessary (see appendix).

Herbal drugs that are subject to contamination by ochratoxin A are tested by a validated method.

The method described below is cited as an example of a method that has been shown to be suitable for liquorice extract and liquorice root. Its suitability for other herbal drugs must be demonstrated or another validated method used.

METHOD

Liquid chromatography (*2.2.29*).

Use brown glassware that is free from detergent residues. If necessary rinse glassware before use with a 10 per cent *V/V* solution of *sulfuric acid R* and then rinse carefully with *distilled water R* until no more acid is present.

Solution A Mix 80 volumes of *water R*, previously adjusted to pH 2.3 with *anhydrous formic acid R*, and 20 volumes of *acetonitrile R*.

Test solution Use an immunoaffinity column containing antibodies against ochratoxin A with a capacity of not less than 100 ng of ochratoxin A and which gives a recovery of not less than 70 per cent. Allow the immunoaffinity column to reach room temperature.

To 2.00 g of the powdered drug (250) (*2.9.12*) add 80 mL of a 30 g/L solution of *sodium hydrogen carbonate R* and extract by sonication for 30 min (change water of ultrasonic bath after 15 min). Cool to room temperature and dilute to 100.0 mL (V_1) with the same solution. Centrifuge. Mix thoroughly 5.0 mL (V_i) of the clear supernatant with 30 mL *buffer solution pH 7.4 R* and pass the whole solution through the immunoaffinity column at a flow rate of 3 mL/min (do not exceed 5 mL/min). Wash the column first with 10 mL *buffer solution pH 7.4 R* then with 2 quantities, each of 10 mL, of *water R* at a flow rate not exceeding 5 mL/min and dry by applying a slight vacuum for 5-10 s or by passing air through the immunoaffinity column by means of a syringe for 10 s. Apply 0.5 mL of *methanol R* to the column and allow to pass through by gravity.

Collect the eluate in a 4 mL glass vial. After 30 s, apply a 2nd quantity of 0.5 mL of *methanol R* and allow to pass through the column by gravity into the same glass vial. After a further 30 s, repeat with a 3rd portion of 0.5 mL of *methanol R*. Collect any solvent retained on the column by pressing air through or applying vacuum to the column. Evaporate the combined eluates completely to dryness using a thermal block with a nitrogen blanket (40 °C). Dissolve the residue in 0.5 mL (V_2) of solution A. If the solution is clear it can be used directly for analysis. Otherwise, pass it through a disposable filter unit prior to injection. Use a disposable filter unit (e.g. 0.45 µm pore size polytetrafluoroethylene filter) that has been shown not to cause loss of ochratoxin A by retention.

Ochratoxin A primary stock solution Dilute 1.0 mL of *ochratoxin A solution R* to 100.0 mL with *methanol R* and shake thoroughly.

Ochratoxin A secondary stock solution Dilute 10.0 mL of ochratoxin A primary stock solution to 100.0 mL with *methanol R* and shake thoroughly.

Ochratoxin A standard solutions Place the volumes of ochratoxin A primary stock solution or ochratoxin A secondary stock solution indicated in Table 2.8.22.-1 into separate flasks and make up to 50.0 mL with solution A.

Table 2.8.22.-1. – *Ochratoxin A standard solutions*

Standard solution	Volume of ochratoxin A primary stock solution (µL)	Final concentration of ochratoxin A in standard solution (ng/mL)
1	5000	50
2	2500	25
3	1000	10
4	500	5
5	250	2.5
Standard solution	**Volume of ochratoxin A secondary stock solution (µL)**	**Final concentration of ochratoxin A in standard solution (ng/mL)**
6	500	0.5
7	100	0.1

Calibration curve Prepare the calibration curve using ochratoxin A standard solutions 1 to 7, which cover a range equivalent to 0.5-250 µg/kg of ochratoxin A in the herbal drug. Check the plot for linearity. If the content of ochratoxin A in the sample to be examined is outside of the calibration range, the test solution must be diluted to an ochratoxin A content that is appropriate for the established calibration curve.

Column:
— *size*: l = 0.15 m, Ø = 4.6 mm;
— *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm);
— *temperature*: 45 °C.

Mobile phase:
— *mobile phase A*: *water R* adjusted to pH 2.3 with *phosphoric acid R*;

— *mobile phase B: acetonitrile R*;

Time (min)	Mobile phase A (per cent *V/V*)	Mobile phase B (per cent *V/V*)
0 - 30	80 → 40	20 → 60
30 - 35	40 → 20	60 → 80
35 - 37	20	80
37 - 40	20 → 80	80 → 20

Flow rate 0.8 mL/min.

Detection Fluorescence detector; recommended settings for adjustable detectors are 330 nm (excitation wavelength) and 460 nm (emission wavelength).

Injection 20 µL.

Calculation Calculate the calibration curve $y = ax + b$, with ochratoxin A concentration (in nanograms per millilitre) on the x-axis and the signal (S) on the y-axis. The ochratoxin A concentration (C) in a measured solution is equal to $\frac{S-b}{a}$.

Calculate the ochratoxin A content of the herbal drug, in nanograms per gram, using the following expression:

$$\frac{V_1 \times V_2 \times C}{m \times V_i}$$

m = mass of the herbal drug used to prepare the test solution, in grams;
V_1 = volume of dilution, in millilitres;
V_i = aliquot taken for immunoaffinity clean-up, in millilitres;
V_2 = volume in which the residue is taken up, in millilitres;
C = measured ochratoxin A concentration of the test solution, in nanograms per millilitre.

APPENDIX: DECONTAMINATION PROCEDURES FOR LABORATORY GLASSWARE

Rinse glassware with *methanol R* and decontaminate by immersion in *strong sodium hypochlorite solution R* for at least 2 h, then wash thoroughly with water.

T. Herbal Drugs: Sampling and Sample Preparation

(Ph. Eur. method 2.8.20)

In order to reduce the effect of sampling in qualitative and quantitative analysis, it is necessary to ensure that the composition of the sample used is representative of the batch of material being examined. The following procedures are the minimum considered applicable for herbal drugs. *NOTE: other procedures may be used if they can be demonstrated to produce representative batch samples.*

BULK SAMPLE

Where external examination of containers, markings and labels of a batch indicate that it can be considered to be homogeneous, sample the number of randomly selected containers indicated below. Where a batch cannot be considered to be homogeneous, divide it into sub-batches that are as homogeneous as possible, then sample each sub-batch as a homogeneous batch using, as a minimum, the number of randomly selected containers indicated below.

Number of containers in batch (N)	Number of containers to be sampled (n)
1 - 3	all
> 3	$n^* = \sqrt{N} + 1$

* round n up to the next integer

Take one sample from each container to be sampled. The sample is taken from the upper, middle or lower section of the container, such that the samples taken are representative of different parts of the containers. In the case of large bales or bags, samples must be taken from a depth of at least 10 cm. The mass of the material taken from each container is such that the total mass of the bulk sample complies with the following values.

Mass of herbal drug in the batch (kg)	Minimum mass of samples as a percentage of the mass of the batch of herbal drug
< 50	1.00*
50 - 100	0.50
> 100 - 250	0.25
> 250 - 500	0.20
> 500 - 1000	0.18
> 1000 - 2500	0.15
> 2500 - 5000	0.10
> 5000 - 10 000	0.08
> 10 000 - 25 000	0.05

NOTE: if the mass of the batch is greater than 25 000 kg, it is divided into sub-batches, and the procedure is applied to each sub-batch as though it were a homogeneous batch.

* subject to a minimum total mass of 125 g for the bulk sample; if this minimum requirement represents more than 10.0 per cent of the mass of herbal drug in the batch, the whole batch may be used as the sample.

Prepare the bulk sample by combining and thoroughly mixing the samples taken from each of the randomly selected containers (see Table 2.8.20.-1).

TEST SAMPLE

Unless otherwise prescribed in the monograph, prepare the test sample as follows.

Reduce the size of the bulk sample by quartering (see Note below) or by any other method that produces a homogeneous sample, making sure that each retained portion remains representative of the whole, until the minimum retained quantity complies with the following conditions.

Type of herbal drug	Minimum weight of test sample
Roots, rhizomes, bark, herbs	500 g or mass of whole sample if bulk sample is less than 500 g
Leaves, flowers, seeds, fruits	250 g or mass of whole sample if bulk sample is less than 250 g
Broken or fragmented drugs (where average mass of the pieces is less than 0.5 g)	125 g

NOTE: quartering consists of placing the bulk sample, thoroughly mixed, as a level and square-shaped heap and dividing it diagonally into 4 equal parts. 2 opposite quarters are retained and carefully remixed. The process is repeated as necessary until the required minimum mass is obtained for the test sample.

Mill the test sample in a single pass through a 1 mm screen or the screen size specified in the monograph. The use of a milling machine is recommended.

Pass the milled sample through a 1 mm standard sieve or the sieve specified in the monograph. The residue retained on the sieve must not be more than 10 per cent of the total

Table 2.8.20.-1. – *Operation of the sampling procedure in order to obtain the prescribed bulk sample*

Mass of herbal drug in container (kg)	0.5			1			5		
Total mass of herbal drug in the batch (kg)	No. of containers in batch	No. of containers to be sampled	Total mass of samples (g)	No. of containers in batch	No. of containers to be sampled	Total mass of samples (g)	No. of containers in batch	No. of containers to be sampled	Total mass of samples (g)
0.5	1	1	125	–	–	–	–	–	–
1	2	2	125	1	1	125	–	–	–
5	10	5	125	5	4	125	1	1	125
10	20	6	125	10	5	125	2	2	125
25	–	–	–	25	6	250	5	4	250
100	–	–	–	100	11	500	20	6	500
250	–	–	–	–	–	–	50	9	625
500	–	–	–	–	–	–	100	11	1000
Mass of herbal drug in container (kg)	**25**			**125**			**500**		
Total mass of herbal drug in the batch (kg)	**No. of containers in batch**	**No. of containers to be sampled**	**Total mass of samples (g)**	**No. of containers in batch**	**No. of containers to be sampled**	**Total mass of samples (g)**	**No. of containers in batch**	**No. of containers to be sampled**	**Total mass of samples (g)**
25	1	1	250	–	–	–	–	–	–
100	4	3	500	–	–	–	–	–	–
250	10	5	625	2	2	625	–	–	–
500	20	6	1000	4	3	1000	1	1	1000
1000	40	8	1800	8	4	1800	2	2	1800
2000	80	10	3000	16	5	3000	4	3	3000
3000	120	12	3000	24	6	3000	6	4	3000
5000	200	16	5000	40	8	5000	10	5	5000
10 000	400	21	8000	80	10	8000	20	6	8000
25 000	800	30	12 500	160	14	12 500	40	8	12 500

mass of the milled sample, of which not more than 2 per cent of the total mass of the milled sample may be of a particle size greater than 1.5 mm or 1.5 times the specified particle size in the monograph. If these conditions are met, the sample and residue are to be well mixed to form the test sample for analysis.

In those cases where these requirements are not met, the test sample for analysis is composed of the 2 parts measured separately. Therefore, the quantity required for each analysis is derived by weighing proportional quantities of the powder and the residue.

NOTE: for determination of microscopic characters, a portion of the milled test sample is re-milled through a 0.355 mm screen.

U. Microscopic Examination of Herbal Drugs

(Ph. Eur. method 2.8.23)

The microscopic examination of herbal drugs is carried out on the powdered drug (355) (*2.9.12*) unless otherwise prescribed in the monograph.

Chloral hydrate solution R is the most commonly prescribed reagent. However, certain features are not visible or not easily seen after mounting in this reagent. In this case, other reagents are used, for example, a 50 per cent *V/V* solution of *glycerol R*, which makes it possible to visualise starch granules. It may also be necessary to prescribe specific reagents in a monograph, for example: *lactic reagent R* which is used to show the presence of various features, 10 per cent *V/V* alcoholic solution of *phloroglucinol R* and *hydrochloric acid R*, which are used to identify the presence of lignin in cells or tissues, *ruthenium red solution R*, which is used to show the presence of mucilage in cells or *glycerol R* used to show the presence of starch and inulin.

Examination under polarised light (between crossed nicol prisms) is used to identify starch granules (black cross phenomenon), calcium oxalate crystals (refringence) or lignified structures.

MOUNTING IN CHLORAL HYDRATE SOLUTION

Place 2-3 drops of *chloral hydrate solution R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. Heat the preparation very gently to boiling on a hot plate or a micro gas burner. Maintain gentle boiling for a short time. Make sure that the quantity of mounting fluid is sufficient. If necessary, add more fluid using a tapered glass pipette. Allow to cool and then examine under a microscope. Repeat the heating until the starch granules and the water-soluble contents of the cells are no longer visible. Examine under a microscope.

Chloral hydrate tends to crystallise as long needles. To avoid this, proceed as follows: after heating, remove the cover slip; to the preparation add 1 drop of a 10 per cent *V/V* mixture of *chloral hydrate solution R* in *glycerol R*; place a clean cover slip on the preparation; examine under a microscope.

MOUNTING IN A 50 PER CENT *V/V* SOLUTION OF GLYCEROL

Place 2 drops of a 50 per cent *V/V* solution of *glycerol R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. Examine under a microscope.

MOUNTING IN A 10 PER CENT *V/V* ALCOHOLIC SOLUTION OF PHLOROGLUCINOL AND HYDROCHLORIC ACID

Place a very small quantity of the powdered drug on a glass microscope slide. Add 1-2 drops of a 10 per cent *V/V* alcoholic solution of *phloroglucinol R*. Mix and allow the solvent to evaporate almost completely. Add 1-2 drops of *hydrochloric acid R* and cover the preparation with a cover slip. Examine immediately under a microscope. The red colour indicates the presence of lignin.

MOUNTING IN LACTIC REAGENT

Place 2-3 drops of *lactic reagent R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. Heat the preparation very gently to boiling. Maintain gentle boiling for a short time. Make sure that the quantity of mounting fluid is sufficient. If necessary, add more fluid using a tapered glass pipette. Allow to cool and then examine under a microscope. Lignified structures stain bright yellow; structures containing cellulose remain colourless. Starch granules stain more or less violet; certain secretions (e.g., essential oils, resins, oleoresins) stain orange and cork stains red.

MOUNTING IN RUTHENIUM RED SOLUTION

Place 2 drops of *ruthenium red solution R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. After about 1 minute, allow a drop of *distilled water R* to be taken up between the slide and the cover slip. Examine under a microscope. The mucilage stains violet red.

V. Deoxyribonucleic Acid (DNA) Based Identification Techniques for Herbal Drugs

1. INTRODUCTION

Deoxyribonucleic Acid (DNA) barcoding has been widely used as a molecular method for the identification of herbal drugs. This method uses short regions of DNA with species specific sequences as barcodes for recognition. Within the British Pharmacopoeia, selected barcode sequences will be the basis for any molecular identification technique. Where a DNA-based method is specified within a monograph as an identification method, the identified region and its species specific sequence will be published as part of the monograph. An example of a barcoding protocol is given below and contains the methodology and the sequence of the region identified as specific to *Ocimum tenuiflorum*.

DNA barcoding of plant material is achieved by a multistage procedure involving DNA extraction, polymerase chain reactions (PCRs) and Sanger sequencing. DNA-based identification techniques for herbal drugs utilise PCR in the following two applications:

(a) to sequence a target region of DNA that contains key characters for species identification,

(b) the use of a species specific PCR for a target DNA sequence and subsequent detection of the amplicon.

The principles and quality requirements for these two applications are described. Alternate methods may be used if they comply with the quality requirements described below.

2. SCOPE OF METHOD

To establish the requirements for DNA extraction from herbal drug material and the use of this extracted DNA for either:

(a) amplification and sequencing of a target region of the extracted DNA for the purposes of species identification; or,

(b) amplicon production and detection techniques to demonstrate the presence of a defined DNA sequence as indicated in (a) and (b) under INTRODUCTION.

3. PRINCIPLE OF THE METHOD

DNA sequences for the identification of herbal drugs can be detected by either direct DNA sequencing or species specific amplification. Both techniques rely on the complementary base pairing of DNA. PCR must be utilised to amplify the target region.

KEY STAGES OF PCR ARE:

- — double stranded DNA is denatured at high temperature to form single stranded DNA;
- — two primers bind specifically to regions flanking the sequence to be amplified, one on either strand of DNA;
- — a thermo-stable polymerase enzyme constructs the complementary DNA sequence starting from the primer binding positions;
- — the three processes described above are repeated as required by the protocol, (typically between 30 and 40 times) to result in the formation of millions of copies of the sequence between the primer binding positions; this is the amplicon;
- — the amplicon is detected by various means and can be used as the template for Sanger sequencing.

KEY STAGES OF SANGER SEQUENCING ARE:

- — the amplicons are denatured at high temperature to form single stranded DNA amplicons;

— one primer is used (this may be one used in the original PCR) and binds specifically to one end of the single stranded amplicons;
— a thermo-stable polymerase enzyme constructs the complementary DNA sequence, starting from the primer binding position;
— at random positions the construction of the complementary DNA sequence is halted due to the incorporation of a fluorescently labelled di-deoxynucleotide (ddNTP);
— amplicons are formed of every possible length, each with a fluorescently labelled ddNTP terminal end;
— amplicons are separated by capillary electrophoresis according to their length, and the fluorescent label recorded using a laser;
— the nucleotide identity at each base position of the amplicon is ascertained;
— this process is repeated with another primer (this may be one used in the original PCR) that binds specifically to the opposite end of the single stranded amplicons.

4. LABORATORY SET-UP REQUIREMENTS

Because of the high risk of contamination of the working materials with environmental, user or different sample DNA, segregation of working areas by time and/or space is an effective method of reducing this risk. The movement of people and materials between working areas should be kept to a minimum and be monitored. All areas should be suitably decontaminated before and after each use and safeguards introduced to prevent cross contamination of samples.

Recommended working areas include:
— ***DNA extraction*** for the use of reagents and equipment used to extract DNA from plant materials;
— ***Pre-PCR*** exclusively for the use of reagents, equipment and materials that have not encountered amplicons;
— ***PCR*** equipment positioned in a dedicated area for the amplification process which occurs in a closed system;
— ***post-PCR*** dedicated to amplicon detection methods, as for instance gel electrophoresis and UV transillumination.

5. DNA EXTRACTION

Pure DNA must be isolated from the herbal drug to be tested. Several methods are available for this purpose, including those based on commercial kits. Representative samples must be taken from each batch to be tested to ensure consistency, Appendix XI T. *Herbal Drugs: Sampling and Sample Preparations*. DNA extraction using 200 mg of herbal drug as a superfine powder is suitable for the test. DNA extraction should also be performed on herbal drug mixed with *trnH-psbA* BP Nucleic Acid Reference Material (BPNARM). The efficiency of the extraction shall be confirmed by PCR amplification of the *trnH-psbA* BPNARM and herbal drug DNA.

Many constituents present in herbal drugs are inhibitory to enzyme driven reactions such as PCR. Care must be taken to ensure that DNA used for testing is pure and sufficiently free from inhibitors. Inhibitors extracted with DNA can be removed by the use of purification procedures, an example is given under: DNA-BASED IDENTIFICATION OF *OCIMUM TENUIFLORUM* LINN (Holy Basil); 2. DNA PURIFICATION.

6. AMPLIFICATION

PCR amplification is conducted using defined cycling parameters, including denaturation and binding temperatures. Many different commercial enzymes and kits are available which can be used once validated for the intended purpose. When commercial kits are used the manufacturers' guidelines for optimisation should be followed.

The concentrations shown below may be used as a generic starting point for method optimisation: Polymerase buffer (1x), $MgCl_2$ (2.5 mM), DNA polymerase (1 Unit), Primers (0.1 µM each), dNTPs (0.1 µM each), DNA (10 ng may be suitable) and *water MB*.

To conduct a PCR the number of reactions required must be known. From each DNA extraction, 2 PCRs are required together with a positive and a negative control reaction. All common components should be measured and combined together to create a master mix, usually this will contain all solutions except the DNA. The master mix is divided equally between each reaction tube and the DNA is added individually.

All PCR tests should include relevant positive and negative controls. To the positive control reaction validated DNA should be added. A solution of *trnH-psbA* BPNARM is recommended. To the negative control, *water MB* should be added in place of the DNA.

7. DETECTION

Specific amplicons may be detected based on their size or composition.

Detection by size can be achieved by agarose gel electrophoresis or capillary electrophoresis.

Detection by sequence can be achieved by probe hybridisation or enzyme cleavage. Amplicon size and sequence both contribute to melt-curve analyses.

A valid test is only achieved if the positive control reaction(s) gives an unambiguously positive result and the negative control reaction gives an unambiguously negative result. A positive result can be shown by the presence of a band of the expected size using agarose gel electrophoresis. A negative result will be the absence of a band.

8. SEQUENCING

Sanger sequencing can be conducted using various commercially available kits and/or service providers. Any validated protocol may be followed and manufacturers' guidelines may be used with commercial kits. A minimum of two reads must be produced for each DNA amplification, with at least one in either direction, and assembled into a contig. The contig should have an overall Phred score of at least 20; a value of 30 and over is preferable.

The text below is provided for information and describes the application of DNA-Based Identification techniques to a herbal drug.

DNA-BASED IDENTIFICATION OF *OCIMUM TENUIFLORUM* LINN. (HOLY BASIL)

1. DNA EXTRACTION

Follow the procedure described in Appendix XI V, 5. DNA EXTRACTION.

2. DNA PURIFICATION

Care should be taken to ensure that inhibitory substances commonly found in *Ocimum tenuiflorum* herbal drug are removed from DNA subsequent to extraction. Many methods are available for this, as for instance the method using propan-2-ol MB described below:
— to 50 µL of DNA extraction solution add 35 µL of *propan-2-ol MB* at 4°, mix by pipetting;
— centrifuge at 14,000 revolutions per minute for 30 minutes at 4°;
— remove the supernatant, taking care not to disturb the pellet which may not be visible;

— re-suspend the pellet in 200 µL of *ethanol (70%)* at ambient temperature;
— centrifuge at 14,000 revolutions per minute for 10 minutes at ambient temperature;
— remove the supernatant liquid taking care not to disturb the pellet, allow any excess ethanol to evaporate at ambient temperature for at least 25 minutes or until dry.
— dissolve the pellet in 50 µL of *tris-EDTA buffer pH 8.0*;
— dilute 1 volume of the DNA solution with 9 volumes of *tris-EDTA buffer pH 8.0* immediately prior to testing.

3. AMPLIFICATION

Prepare as described in Appendix XI V, 6. AMPLIFICATION.

Amplification of the *trnH-psbA* region of the plastid genome is achieved using the following primers and cycling programme.

Primer name	Sequence (5′ to 3′)
tmH	CGCGCATGGTGGATTCACAATCC
psbA	GTTATGCATGAACGTAATGCTC

Cycling programme:

initial denaturation step at 95° for 5 minutes;

35 cycles consisting of
— 95° for 1 minute;
— 30 seconds at touchdown temperature;
— 72° for 1 minute;

final extension period at 72° for 7 minutes;

The touchdown temperature begins at 58° and is reduced by 1° per cycle until 48°, then continued at 48° for the remainder of the program.

If amplification is unsuccessful after purification and dilution of the DNA sample, secondary PCR using 1 µL of the initial amplification as the template for a second is acceptable using the same parameters.

4. AMPLICON DETECTION

Any validated method may be used for this purpose; agarose gel electrophoresis incorporating a DNA specific dye is suitable. Recommended parameters are a 1.0% w/v gel made with 0.5x *TBE buffer MB*, run at 60V for 1 hour and subsequently visualised in an appropriate system such as a UV transilluminator.

A positive result is shown by the presence of a band of the expected size (approximately 400 bp); a DNA ladder should be run adjacent to the samples to show size separation.
A negative result is shown by the absence of a band at this position on the gel.

5. SEQUENCING

The amplicon is sequenced using the amplification primers and is conducted as described under Appendix XI V, 8. SEQUENCING

6. *OCIMUM TENUIFLORUM TRNH-PSBA* REGION SEQUENCE

The sequence of the *trnH-psbA* spacer region for *Ocimum tenuiflorum* is given below, with the bases shown in lower case text being the key bases for identification. These must be checked against all contigs produced using multiple alignment software (Clustal Omega may be suitable).

```
>Ocimum_trnH-psbA_reference_sequence
GTTATGCATGAACGTAATGCTCATAACTTCCCTCTAGACCTAGCTGCTAT
TGAAGCTCCAACAAATGGCTAAGacttgttCTTGGTGTGTAGAAGTTTTT

TTTTTAGATTTTTAGAGTAGAGGGGCGGATGTAGCCAAGTGGATCAAGGC
AGTGGattgtGAATCCACCCATGCGCG
```

7. SEQUENCE MATCHING

trnH-psbA sequences for the identification of *Ocimum tenuiflorum* samples must be a minimum of 300 bp in length, and must cover the key bases for identification. Overall matching of the sequences should be above 95%, and the key bases must match 100% with no gaps.

DNA-BASED IDENTIFICATION OF *ANETHUM GRAVEOLENS* SOWA

1. DNA EXTRACTION

Follow the procedure described in Appendix XI V, 5. DNA EXTRACTION.

2. DNA PURIFICATION

DNA extracted from *Anethum graveolens* Sowa does not require further purification; however, a 1:10 dilution in *Tris-EDTA buffer pH 8.0* can enhance results.

3. AMPLIFICATION

Prepare as described in Appendix XI V, 6. AMPLIFICATION.

Amplification of the ITS2 region of the nuclear genome is achieved using the following primers and cycling programme.

Primer name	Sequence (5′ to 3′)
ITS2 Forward	ATGCGATACTTGGTGTGAAT
ITS2 Reverse	GACGCTTCTCCAGACTACAAT

Cycling programme:
— initial denaturation step at 95° for 5 minutes;
— 40 cycles consisting of
— 95° for 30 seconds;
— 56° for 30 seconds;
— 72° for 45 seconds;
— final extension period at 72° for 10 minutes.

4. AMPLICON DETECTION

Any validated method, which incorporates a DNA ladder, may be used for this purpose; agarose gel electrophoresis incorporating a DNA specific dye is suitable. Recommended parameters are a 2.0% w/v gel made with 0.5x *TBE buffer MB*, run at 60 V for 1 hour and subsequently visualised in an appropriate system such as a UV transilluminator.

A positive result is shown by the presence of a band of the expected size (approximately 480 bp); a DNA ladder should be run adjacent to the samples to show size separation.
A negative result is shown by the absence of a band at this position on the gel.

5. SEQUENCING

The amplicon is sequenced using the amplification primers and is conducted as described under Appendix XI V, 8. SEQUENCING

6. *ANETHUM GRAVEOLENS* SOWA ITS2 REGION SEQUENCE

The sequence of the ITS2 region for *Anethum graveolens* Sowa is given below, with the bases shown in lower case text being the key bases for identification. These must be checked

against all contigs produced using multiple alignment software (Clustal Omega may be suitable).

```
>Anethum_graveolens_Sowa_ITS2_reference_sequence
TTTGCTTGCCCCAACCACTCACTCCTTGATGAGATGTGCTGGTTTTTGGG

acACAATCTGTTTGCCCTAACTGTGACCCCAGGTCAGGCG
```

7. SEQUENCE MATCHING

ITS2 sequences for the identification of *Anethum graveolens* Sowa samples must be a minimum of 240 bp in length, and must cover the key bases for identification. Overall matching of the sequences should be above 95%, and the key bases must match 100% with no gaps.

DNA-BASED IDENTIFICATION OF *TRIBULUS TERRESTRIS* FRUIT

1. DNA EXTRACTION

Follow the procedure described in Appendix XI V, 5. DNA EXTRACTION.

2. DNA PURIFICATION

DNA extracted from *Tribulus terrestis* Fruit does not require further purification.

3. AMPLIFICATION

Prepare as described in Appendix XI V, 6. AMPLIFICATION.

Amplification of the ITS2 region of the nuclear genome is achieved using the following primers and cycling programme.

Primer name	Sequence (5′ to 3′)
ITS1 Forward	TCCGTAGGTGAACCTGCGG
ITS4 Reverse	TCCTCCGCTTATTGATATGC

Cycling programme:
— initial denaturation step at 95° for 5 minutes;
— 35 cycles consisting of
— 95° for 60 seconds;
— 60° for 30 seconds;
— 72° for 60 seconds;
— final extension period at 72° for 7 minutes.

4. AMPLICON DETECTION

Any validated method, which incorporates a DNA ladder, may be used for this purpose; agarose gel electrophoresis incorporating a DNA specific dye is suitable. Recommended parameters are a 2.0% w/v gel made with 0.5x *TBE buffer MB*, run at 60 V for 1 hour and subsequently visualised in an appropriate system such as a UV transilluminator.

A positive result is shown by the presence of a band of the expected size (approximately 700 bp); a DNA ladder should be run adjacent to the samples to show size separation.
A negative result is shown by the absence of a band at this position on the gel.

5. SEQUENCING

The amplicon is sequenced using the amplification primers and is conducted as described under Appendix XI V, 8. SEQUENCING

6. *TRIBULUS TERRESTRIS* FRUIT ITS REGION SEQUENCE

The sequence of the ITS region for *Tribulus terrestris* Fruit is given below, with the bases shown in lower case text being the key bases for identification. These must be checked against all contigs produced using multiple alignment software (Clustal Omega may be suitable).

```
>Tribulus_terrestris_ITS_reference_sequence
CACtcgygcgATGCGTTCCACGctctccaCGGGGACTTGgccaccgcgcg

AGTGCACTATTactACACGAACGACTCTCGGCAACGGATATCTCGGCTCT
CGCATCGATGAAGAACGTAGCGAAATGCGATACTT
```

7. SEQUENCE MATCHING

Amplification of the ITS region for the identification of *Tribulus terrestris* samples yields a product of approximately 700 bp, within the amplification product lies the reference sequence which must be a minimum of 235 bp in length, and must cover the key bases for identification. Overall matching of the sequences should be above 95%, and the key bases must match 100% with no gaps.

GLOSSARY

This glossary of terms relating to Appendix XI V is published for information only

Table XI V-1

Term	Definition
Amplicon	The DNA product of a PCR.
Amplification	The copying of DNA during a PCR.
Base call	The identification of a DNA base by sequencing software.
Base pair (bp)	The complementary pairing of two nucleotides, A&T or G&C, which forms the unit of measurement for the length of a DNA molecule.
BPNARM	British Pharmacopoeia Nucleic Acid Reference Material.
Consensus sequence	The product of the combining of several individual DNA sequencing reads, providing a consensus of the correct sequence.
Contig	A set of overlapping DNA sequencing reads from one sample which can be used to produce a consensus sequence.
Deoxynucleotide (dNTP)	The monomer or individual unit of DNA; Adenine (A), Cytosine (C), Guanine (G) and Thymine (T).
di-deoxynucleotide (ddNTP)	A modified form of the DNA monomer without an -OH group present on the 3′ carbon of the deoxyribose sugar which is required to bind a subsequent nucleotide.
DNA	Deoxyribonucleic Acid, a double stranded, helical molecule.
DNA ladder	Mixture of DNA molecules of known base pair length. These provide a measure of how far a DNA molecule travels during gel electrophoresis.
Internal transcribed spacer (ITS)	The spacer DNA situated between the small-subunit ribosomal RNA (rRNA) and large-subunit rRNA genes in the chromosome or the corresponding transcribed region in the polycistronic rRNA precursor transcript
Mix by pipetting	Drawing up and expelling a substance up to ten times using an automatic pipette, with the aim of mixing the solutions.
Master mix	A mixture containing the common components for several PCRs, this is made in a large batch or master mix which is then divided between individual reactions. Master mixes contain enough reagents for the required number of tests, typically plus one to allow for pipetting errors.
Mix by pipetting	Drawing up and expelling a substance up to ten times using an automatic pipette, with the aim of mixing the solutions.
PCR	Polymerase Chain Reaction - an enzyme driven reaction where DNA molecules are replicated.
Phred score	The likelihood that a base call in a DNA sequence is incorrect, a score of 20 has a 1 in 100 probability of being an incorrect call, 30 is 1 in 1000 etc.
Positive control	A reaction comprising all common PCR components and a known DNA sample, thereby proving the suitability of all reagents.
Primer (oligonucleotide)	A short single stranded DNA molecule which binds to the DNA to be amplified in a PCR. This enables the enzyme to commence replication, and therefore the binding positions define the start and finish point of the PCR.
Probe hybridisation	The complementary binding of an oligonucleotide to a target DNA molecule causing a measurable response.
Sanger sequencing	The method by which a DNA sequence is resolved, developed by Frederick Sanger and colleagues.
Sequencing	Identifying the order of the nucleotide sequence of DNA.
TBE buffer MB	Tris-borate-EDTA Buffer Solution pH 8.4 MB
Thermal cycler	The machine that performs the cycling of temperatures required for a PCR.
Water MB	Deionised, filtered and autoclaved water.

W. High-Performance Thin-Layer Chromatography of Herbal Drugs and Herbal Drug Preparations

(Ph. Eur. method 2.8.25)

High-performance thin-layer chromatography (HPTLC) is used for qualitative analysis of herbal drugs and herbal drug preparations. It is a thin-layer chromatographic technique (*2.2.27*) that usually uses a glass plate coated with a uniform, porous layer (average pore size 6 nm), typically 200 µm thick, of irregular particles of silica gel between 2 µm and 10 µm in size and with an average size of 5 µm, a polymeric binder and a fluorescence indicator (F_{254}). The results are qualified using a system suitability test.

EQUIPMENT

The equipment used for qualitative HPTLC typically consists of:

- glass plates, as described above, usually 20 × 10 cm in size;
- devices suitable for the application of specified volumes of solutions as bands and allowing control of the dimensions and position of application;
- a device suitable for conditioning the stationary phase at the prescribed relative humidity;
- a suitable chromatographic tank (for example, a twin trough chamber);
- a device suitable for the reproducible drying of the developed plate;
- devices suitable for the application of reagents to, and heating of, the plate as part of the derivatisation procedure;
- a system suitable for the electronic documentation of chromatograms under 254 nm UV, 366 nm UV and white light.

NOTE Normal thin-layer chromatographic methods using glass plates or sheets coated with particles of 5-40 µm or HPTLC aluminium-backed sheets may be used, provided that the results obtained fulfil the general system suitability criteria that the bands develop perpendicular to the lower edge of the plate and the solvent front is parallel to the upper edge of the plate, and satisfy the system suitability test stated in the individual monograph.

METHOD

Preparation of test solution

The test solution is prescribed in the individual monograph and is usually prepared as follows.

For dry herbal drugs or dry herbal extracts, mix 0.5 g of the powdered herbal drug or 0.1 g of the dry herbal extract with 5.0 mL of *methanol R* and sonicate for 15 min; filter or centrifuge and use the filtrate or supernatant as the test solution.

For essential oils, dissolve 50 µL of the essential oil in 1.0 mL of *toluene R* and use this solution as the test solution.

Preparation of reference solutions

Reference solutions are prescribed in the individual monograph and are usually prepared as follows. Prepare a 1 mg/mL solution (identified as 'R' in the chromatograms associated with the monograph) of suitable reagent(s) or reference standard(s) in *methanol R* or, for essential oils, in *toluene R*. Prepare a second reference solution (diluted reference solution, identified as 'R1/4' in the chromatograms associated with the monograph) by mixing 1 volume of this solution and 3 volumes of the same solvent (in some cases a different diluted reference solution, e.g. 'R1/20', may be prescribed instead). Both solutions are used as intensity references.

Intensity marker

Use one or more of the substances in the reference solution and in the diluted reference solution as intensity marker(s) for the evaluation of the chromatogram.

Preparation of system suitability test solution

Prepare the system suitability test (SST) solution as stated in the individual monograph.

Sample application and plate layout

Samples are usually applied as narrow bands 8 mm in length at a distance of 8 mm from the lower edge of the plate. The centre of the first track, which is used for the system suitability test solution, is positioned 20 mm from the left edge of the plate. The minimum distance between tracks (centre to centre) is 11 mm. A maximum of 15 tracks are applied onto a standard plate. If no electronic solvent front detection device is used, the development distance is marked with a pencil close to the right or left edge of the plate.

Conditioning of the plate

Following sample application and unless otherwise stated in the individual monograph, expose the plate to air with a suitable relative humidity obtained using a saturated solution of *magnesium chloride R* (for example, by allowing the plate to stand in a closed chamber containing such a solution for 1 h or by using preconditioned air).

Preparation of the tank and development of the plate

Unless otherwise stated in the individual monograph, the chromatographic separation is performed in a saturated tank. Where a twin trough chamber is used, place a piece of filter paper in the rear trough. Load the tank with a sufficient quantity of mobile phase to wet the filter paper completely and achieve a level of 5 mm in both troughs. With the lid closed, leave the tank for 20 min for saturation. Introduce the plate in a vertical position into the front trough of the tank so that the coating layer faces the filter paper. When the mobile phase has reached the prescribed distance (usually 70 mm from the lower edge of the plate), remove the plate from the tank and dry in a vertical position in a stream of air at room temperature. Other tank configurations and development distances may be specified in an individual monograph.

NOTE Other tanks may be employed if the results obtained fulfil all of the system suitability criteria.

Visualisation

Chromatograms on the plate are visualised as stated in the individual monograph under Detection. Where derivatisation reagents are used, typically 3.5 mL of reagent solution is homogenously sprayed onto a plate of size 20 × 10 cm, or the plate is immersed into the reagent solution, typically at a speed of 5 mm/s for a dwell time of 1 s. Observation may be performed under 254 nm UV, 366 nm UV or white light prior to and/or after derivatisation. When pictures are digitally recorded, exposure time should be adjusted based on the track used for the system suitability test solution.

System suitability test

This test is based on the separation of 2 substances that have similar retardation factors (R_F values) but that are barely separable under the specified chromatographic conditions (for example, chlorogenic acid and hyperoside in chromatographic systems used for flavonoids). The results for the test and reference solutions are only valid when the

system suitability test solution satisfies the separation requirement stated in the individual monograph.

Visual evaluation

The chromatograms obtained with the test and reference solutions are compared with the descriptions in the results section of the individual monograph, with respect to zone position and colour, as well as intensity for the test solution. Zones of the test solution described as 'equivalent' or without an indication of intensity have intensities similar to the zone of the intensity marker in the reference solution (R). Zones described as 'intense' are visually more intense than the zone of the intensity marker in the reference solution; zones described as 'faint' are visually less intense than the zone of the intensity marker in the reference solution, but equal to or more intense than the zone of the intensity marker in the diluted reference solution (R1/4, R1/20, etc.); zones described as 'very faint' are visually less intense than the zone of the intensity marker in the diluted reference solution.

Appendix XII

A. Disintegration

1. Disintegration of Tablets and Capsules[1]

(Ph. Eur. method 2.9.1)

This test is provided to determine whether tablets or capsules disintegrate within the prescribed time when placed in a liquid medium under the experimental conditions presented below.

For the purposes of this test, disintegration does not imply complete dissolution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the discs, if used, is a soft mass having no palpably firm core.

♦Use apparatus A for tablets and capsules that are not greater than 18 mm long. For larger tablets or capsules use apparatus B.♦

TEST A - TABLETS AND CAPSULES OF NORMAL SIZE

Apparatus

The apparatus consists of a basket-rack assembly, a 1 L, low-form beaker, 149 ± 11 mm in height and having an inside diameter of 106 ± 9 mm for the immersion fluid, a thermostatic arrangement for heating the fluid between 35 °C and 39 °C, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles per minute, through a distance of 55 ± 2 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke the wire mesh remains at least 15 mm below the surface of the fluid, and descends to not less than 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition, rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

Basket-rack assembly The basket-rack assembly consists of 6 open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 21.85 ± 1.15 mm and a wall 1.9 ± 0.9 mm thick; the tubes are held in a vertical position by 2 plates, each 90 ± 2 mm in diameter and 6.75 ± 1.75 mm in thickness, with 6 holes, each 24 ± 2 mm in diameter, equidistant from the centre of the plate and equally spaced from one another. Attached to the under surface of the lower plate is a woven stainless steel wire cloth, which has a plain square weave with 2.0 ± 0.2 mm mesh apertures and with a wire diameter of 0.615 ± 0.045 mm. The parts of the apparatus are assembled and rigidly held by means of 3 bolts passing through the 2 plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device using a point on its axis.

The design of the basket-rack assembly may be varied somewhat provided the specifications for the glass tubes and the screen mesh size are maintained. The basket-rack

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

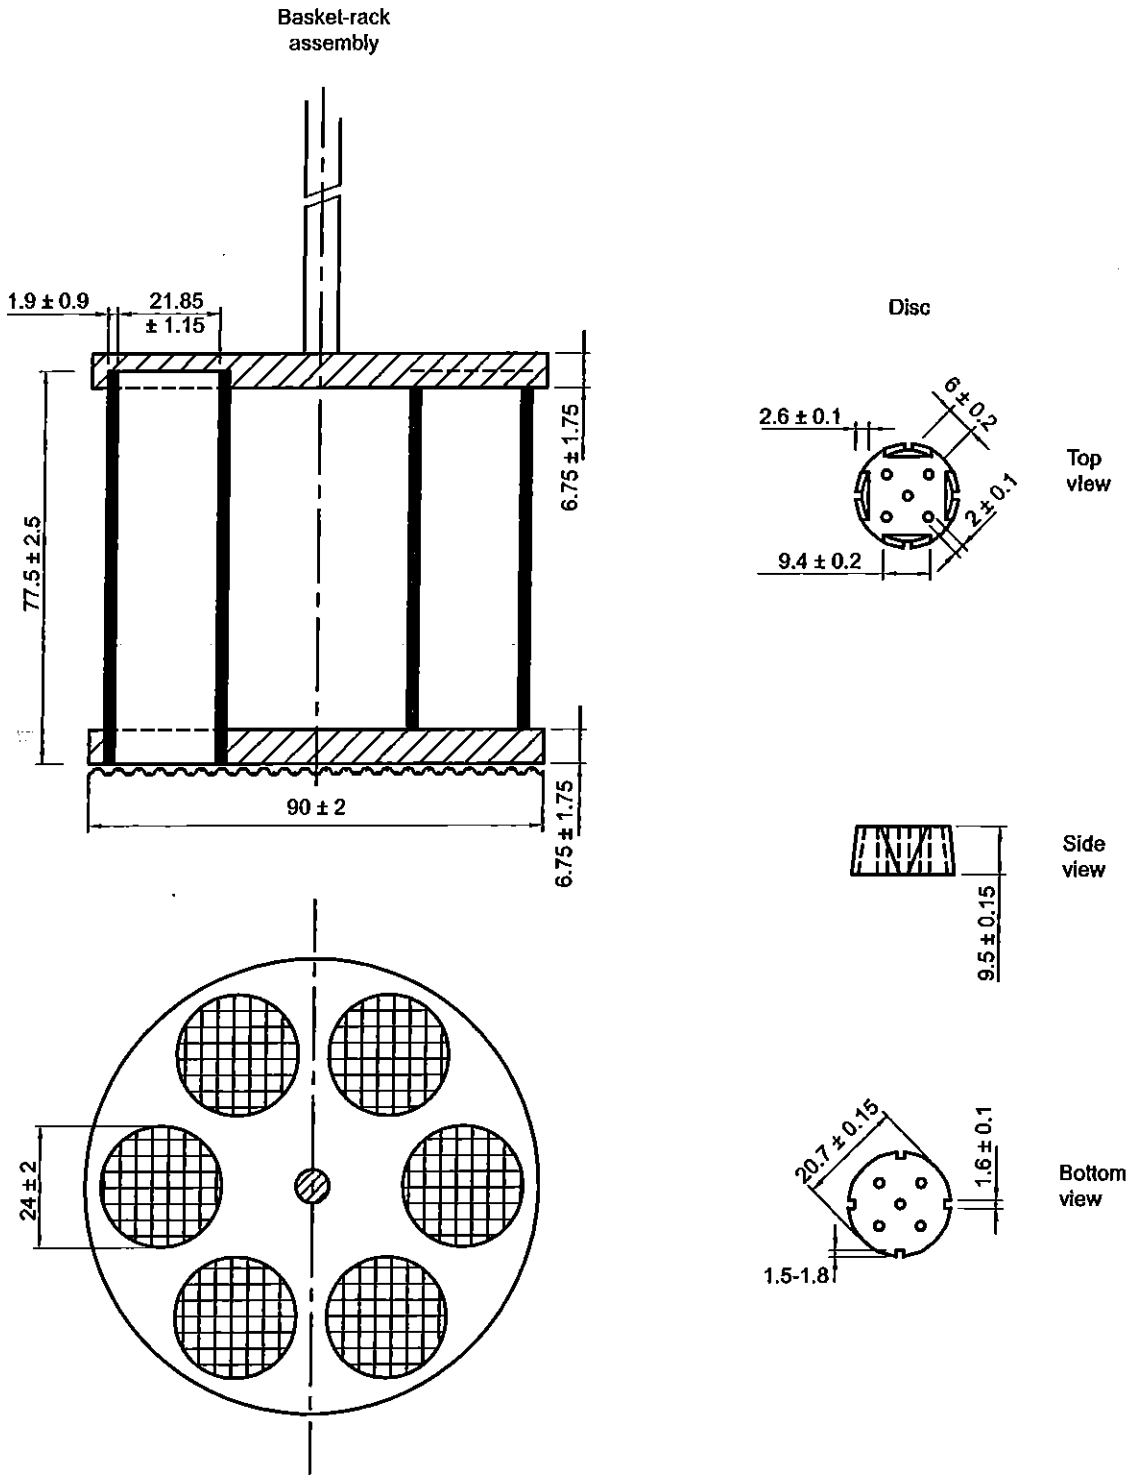

Figure 2.9.1.-1. – *Disintegration apparatus A*
Dimensions in millimetres

assembly conforms to the dimensions shown in Figure 2.9.1.-1.

Discs The use of discs is permitted only where specified or allowed. Each tube is provided with a cylindrical disc 9.5 ± 0.15 mm thick and 20.7 ± 0.15 mm in diameter. The disc is made of a suitable, transparent plastic material having a specific gravity of 1.18-1.20. 5 parallel 2 ± 0.1 mm holes extend between the ends of the cylinder. One of the holes is centered on the cylindrical axis. The other holes are parallel to the cylindrical axis and centered 6 ± 0.2 mm from the axis on imaginary lines perpendicular to the axis and to each other, as defined in Figure 2.9.1.-1. 4 identical trapezoidal-shaped planes are cut into the wall of the cylinder, nearly perpendicular to the ends of the cylinder. The trapezoidal shape is symmetrical; its parallel sides coincide with the ends of the cylinder and are parallel to an imaginary line connecting the centres of 2 adjacent holes 6 mm from the cylindrical axis. The parallel side of the trapezoid on the bottom of the cylinder has a length of 1.6 ± 0.1 mm and its bottom edges lie at a depth of 1.5 mm to 1.8 mm from the cylinder's circumference. The parallel

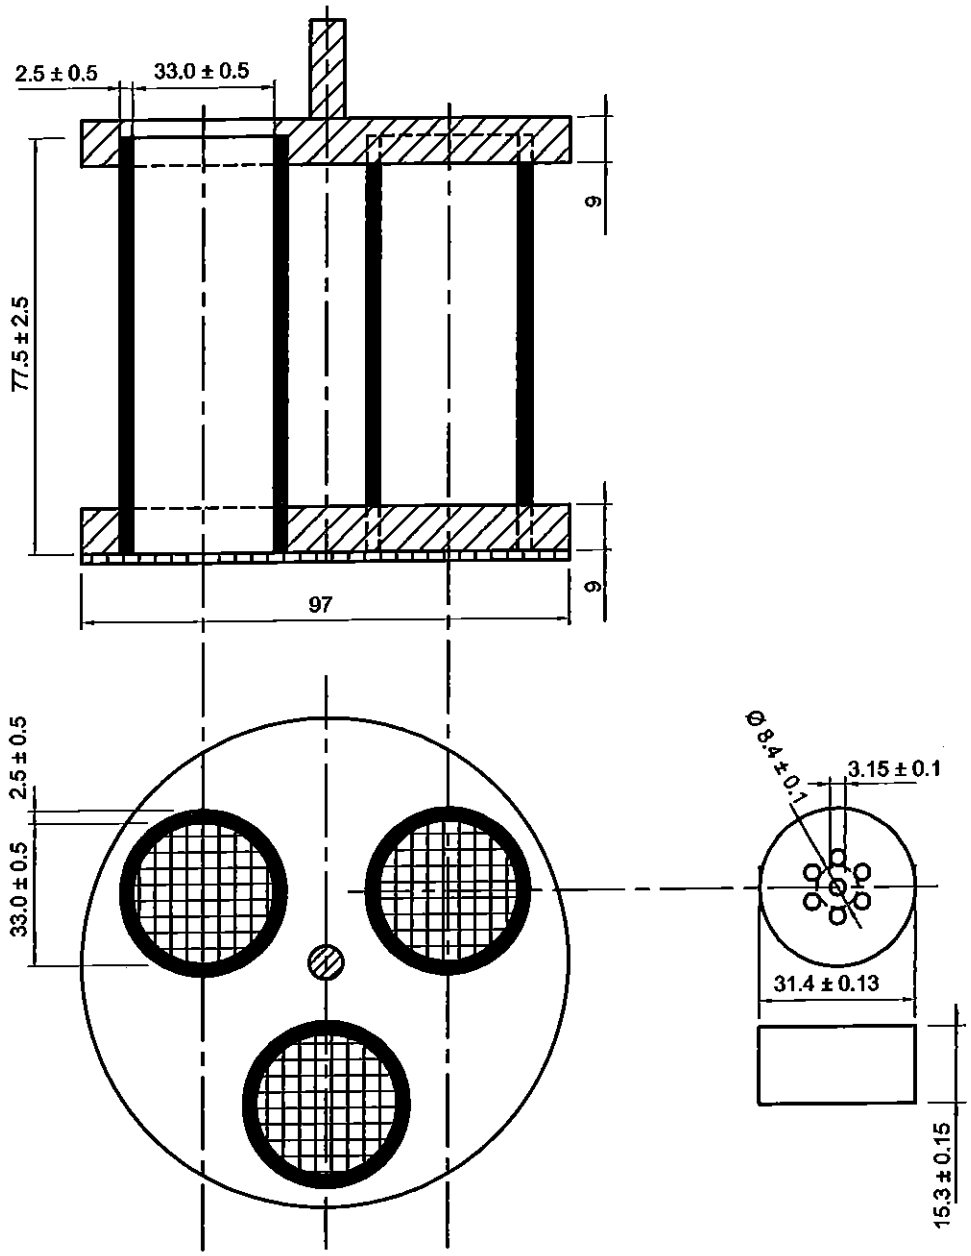

Figure 2.9.1.-2. – *Disintegration apparatus B*
Dimensions in millimetres

side of the trapezoid on the top of the cylinder has a length of 9.4 ± 0.2 mm and its centre lies at a depth of 2.6 ± 0.1 mm from the cylinder's circumference. All surfaces of the disc are smooth.

If the use of discs is specified, add a disc to each tube and operate the apparatus as directed under Procedure. The discs conform to the dimensions shown in Figure 2.9.1.-1.

The use of automatic detection employing modified discs is permitted where the use of discs is specified or allowed. Such discs must comply with the requirements of density and dimension given in this chapter.

Procedure

Place 1 dosage unit in each of the 6 tubes of the basket and, if prescribed, add a disc. Operate the apparatus using the specified medium, maintained at 37 ± 2 °C, as the immersion fluid. At the end of the specified time, lift the basket from the fluid and observe the dosage units: all of the dosage units have disintegrated completely. If 1 or 2 dosage units fail to disintegrate, repeat the test on 12 additional dosage units. The requirements of the test are met if not less than 16 of the 18 dosage units tested have disintegrated.

♦TEST B – LARGE TABLETS AND LARGE CAPSULES

Apparatus

The main part of the apparatus (Figure 2.9.1.-2.) is a rigid basket-rack assembly supporting 3 cylindrical transparent tubes 77.5 ± 2.5 mm long, 33.0 mm ± 0.5 mm in internal diameter, and with a wall thickness of 2.5 ± 0.5 mm. Each tube is provided with a cylindrical disc 31.4 ± 0.13 mm in diameter and 15.3 ± 0.15 mm thick, made of transparent plastic with a relative density of 1.18-1.20. Each disc is pierced by 7 holes, each 3.15 ± 0.1 mm in diameter, 1 in the centre and the other 6 spaced equally on a circle of radius 4.2 mm from the centre of the disc. The tubes are held vertically by 2 separate and superimposed rigid plastic

plates 97 mm in diameter and 9 mm thick, with 3 holes. The holes are equidistant from the centre of the plate and equally spaced. Attached to the under side of the lower plate is a piece of woven gauze made from stainless steel wire 0.63 ± 0.03 mm in diameter and having mesh apertures of 2.0 ± 0.2 mm. The plates are held rigidly in position and 77.5 mm apart by vertical metal rods at the periphery.
A metal rod is also fixed to the centre of the upper plate to enable the assembly to be attached to a mechanical device capable of raising and lowering it smoothly at a constant frequency of between 29 and 32 cycles per minute, through a distance of 55 ± 2 mm.

The assembly is suspended in the specified liquid medium in a suitable vessel, preferably a 1 L beaker. The volume of the liquid is such that when the assembly is in the highest position the wire mesh is at least 15 mm below the surface of the liquid, and when the assembly is in the lowest position the wire mesh is at least 25 mm above the bottom of the beaker and the upper open ends of the tubes remain above the surface of the liquid. A suitable device maintains the temperature of the liquid at 35-39 °C.

The design of the basket-rack assembly may be varied provided the specifications for the tubes and wire mesh are maintained.

Method

Test 6 tablets or capsules either by using 2 basket-rack assemblies in parallel or by repeating the procedure. In each of the 3 tubes, place 1 tablet or capsule and, if prescribed, add a disc; suspend the assembly in the beaker containing the specified liquid. Operate the apparatus for the prescribed period, withdraw the assembly and examine the state of the tablets or capsules. To pass the test, all 6 of the tablets or capsules must have disintegrated.♦

2. Disintegration Test for Suppositories and Pessaries

(Ph. Eur. method 2.9.2)

The disintegration test determines whether the suppositories or pessaries soften or disintegrate within the prescribed time when placed in a liquid medium in the experimental conditions described below.

Disintegration is considered to be achieved when:

a) dissolution is complete,

b) the components of the suppository or pessary have separated: melted fatty substances collect on the surface of the liquid, insoluble powders fall to the bottom and soluble components dissolve, depending on the type of preparation, the components may be distributed in one or more of these ways,

c) there is softening of the sample that may be accompanied by appreciable change of shape without complete separation of the components, the softening is such that the suppository or pessary no longer has a solid core offering resistance to pressure of a glass rod,

d) rupture of the gelatin shell of rectal or vaginal capsules occurs allowing release of the contents,

e) no residue remains on the perforated disc or if a residue remains, it consists only of a soft or frothy mass having no solid core offering resistance to pressure of a glass rod (vaginal tablets).

Apparatus The apparatus (Figure 2.9.2.-1) consists of a sleeve of glass or suitable transparent plastic, of appropriate thickness, to the interior of which is attached by means of three hooks a metal device consisting of two perforated stainless metal discs each containing 39 holes 4 mm in diameter; the diameter of the discs is similar to that of the interior of the sleeve; the discs are about 30 mm apart. The test is carried out using three such apparatuses each containing a single sample. Each apparatus is placed in a beaker with a capacity of at least 4 L filled with water maintained at 36-37 °C, unless otherwise prescribed. The apparatuses may also be placed together in a vessel with a capacity of at least 12 L. The beaker is fitted with a slow stirrer and a device that will hold the cylinders vertically not less than 90 mm below the surface of the water and allow them to be inverted without emerging from the water.

Method Use three suppositories or pessaries. Place each one on the lower disc of a device, place the latter in the sleeve and secure. Invert the apparatuses every 10 min. Examine the samples after the period prescribed in the monograph. To pass the test all the samples must have disintegrated.

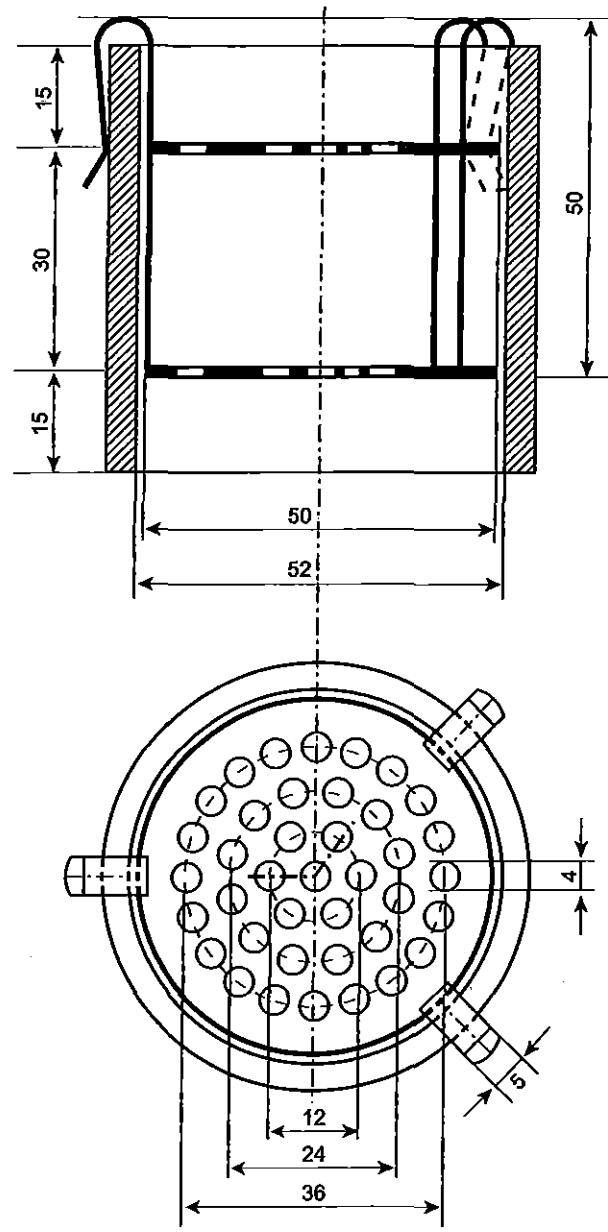

Figure 2.9.2.-1. – *Apparatus for disintegration of suppositories and pessaries*

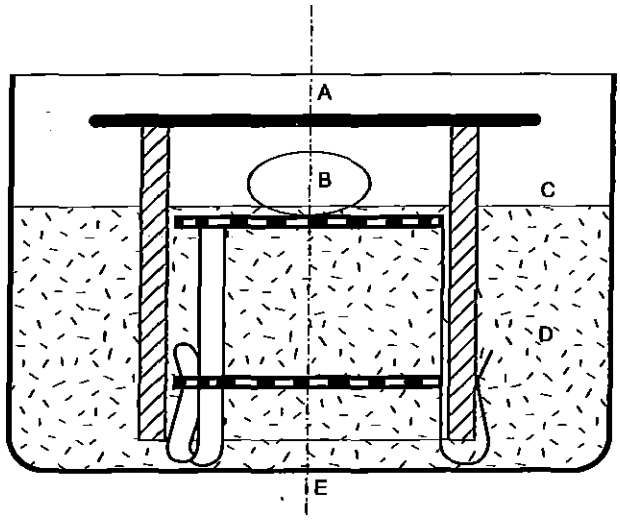
Dimensions in millimetres

METHOD OF OPERATION FOR VAGINAL TABLETS

Use the apparatus described above, arranged so as to rest on the hooks (see Figure 2.9.2.-2). Place it in a beaker of suitable diameter containing water maintained at 36-37 °C with the level just below the upper perforated disc. Using a pipette, adjust the level with water at 36-37 °C until a uniform film covers the perforations of the disc. Use three vaginal tablets. Place each one on the upper plate of an apparatus and cover the latter with a glass plate to maintain appropriate conditions of humidity. Examine the state of the samples after the period prescribed in the monograph.
To pass the test all the samples must have disintegrated.



A. glass plate
B. vaginal tablet
C. water surface
D. water
E. dish, beaker

Figure 2.9.2.-2.

Monographs of the British Pharmacopoeia

The following additional points apply to monographs of the British Pharmacopoeia.

ACCEPTANCE CRITERIA

For moulded suppositories, disintegration occurs in not more than 30 minutes for fat-based suppositories and in not more than 60 minutes for water-soluble suppositories, unless otherwise justified and authorised.

For moulded pessaries, disintegration occurs in not more than 60 minutes unless otherwise justified and authorised.

For rectal capsules and vaginal tablets and capsules, disintegration occurs in not more than 30 minutes.

Recommendations on Dissolution Testing

(Ph. Eur. general texts 5.17.1)

This general chapter is non-mandatory; it provides information on dissolution testing, on recommended dissolution media and on the expression of dissolution specifications for oral dosage forms (see general chapter 2.9.3. Dissolution test for solid dosage forms). This information represents generally accepted parameters used in the field of dissolution.

In the determination of the dissolution rate of the active substance(s) of a solid dosage form, the following are to be specified:

- the apparatus to be used, and in cases where the flow-through apparatus is specified, which flow-through cell is to be used;
- the composition, the volume and the temperature of the dissolution medium;
- the rotation speed or the flow rate of the dissolution medium;
- the time, the method and the amount for sampling of the test solution or the conditions for continuous monitoring;
- the method of analysis;
- the acceptance criteria.

The choice of apparatus to be used depends on the physico-chemical characteristics of the dosage form. When a large quantity of dissolution medium is required to ensure sink conditions, or when a change of pH is necessary, the flow-through apparatus may be preferred.

EXPERIMENTAL TESTING CONDITIONS

The use of the basket and the paddle apparatus and the reciprocating cylinder apparatus is generally based on the principle of operating under sink conditions, i.e. in such a manner that the material already in solution does not exert a significant modifying effect on the rate of dissolution of the remainder. Sink conditions normally occur in a volume of dissolution medium that is at least 3-10 times the saturation volume.

In general, an aqueous medium is used. The composition of the medium is chosen on the basis of the physico-chemical characteristics of the active substance(s) and excipient(s) within the range of conditions to which the dosage form is likely to be exposed after its administration. This applies in particular to the pH and the ionic strength of the dissolution medium.

The pH of the dissolution medium is usually set between pH 1 and pH 8. In justified cases, a higher pH may be needed. For the lower pH values in the acidic range, *0.1 M hydrochloric acid* is normally used. Recommended dissolution media are described hereafter.

Water is recommended as a dissolution medium only when it is proven that the pH variations do not have an influence on the dissolution characteristics.

In specific cases, and subject to approval by the competent authority, dissolution media may contain enzymes, surfactants, further inorganic substances and organic substances. For the testing of preparations containing poorly aqueous-soluble active substances, modification of the medium may be necessary. In such circumstances, a low concentration of surfactant is recommended; it is recommended to avoid the use of organic solvents.

Gases dissolved in the dissolution medium can affect the results of the dissolution test. This is true in particular for the flow-through apparatus, where de-aeration of the medium is necessary to avoid the formation of gas bubbles in the flow-through cell. A suitable method of de-aeration is as follows: heat the medium while stirring gently to about 41 °C, immediately filter under vacuum using a filter with a porosity of 0.45 µm or less, with vigorous stirring, and continue stirring under vacuum for about 5 min. Other de-aeration techniques for removal of dissolved gases may be used.

Using the paddle or basket apparatus, the volume of dissolution medium is normally 500-1000 mL. A stirring speed of between 50 r/min and 100 r/min is normally chosen; it must not exceed 150 r/min.

For the flow-through apparatus, the liquid flow rate is normally set between 4 mL/min and 50 mL/min.

RECOMMENDED DISSOLUTION MEDIA

The following dissolution media may be used.

Table 5.17.1.-1. – *Examples of dissolution media*

pH	Dissolution media
pH 1.0	HCl
pH 1.2	NaCl, HCl
pH 1.5	NaCl, HCl
pH 4.5	Phosphate or acetate buffer
pH 5.5 and pH 5.8	Phosphate or acetate buffer
pH 6.8	Phosphate buffer
pH 7.2 and pH 7.5	Phosphate buffer

The composition and preparation of these various media are indicated below.

Hydrochloric acid media

— *0.2 M hydrochloric acid.*

— *0.2 M sodium chloride.* Dissolve 11.69 g of *sodium chloride R* in *water R* and dilute to 1000.0 mL with the same solvent.

For preparing media with the pH values indicated in Table 5.17.1.-2, mix 250.0 mL of 0.2 M sodium chloride and the specified volume of *0.2 M hydrochloric acid*, and dilute to 1000.0 mL with *water R*.

Table 5.17.1.-2. – *Hydrochloric acid media*

pH	HCl (mL)
1.2	425.0
1.3	336.0
1.4	266.0
1.5	207.0
1.6	162.0
1.7	130.0
1.8	102.0
1.9	81.0
2.0	65.0
2.1	51.0
2.2	39.0

The hydrochloric acid media may also be prepared by replacing sodium chloride with potassium chloride.

Acetate buffer solutions

— *2 M acetic acid.* Dilute 120.0 g of *glacial acetic acid R* to 1000.0 mL with *water R*.

— *Acetate buffer solution pH 4.5.* Dissolve 2.99 g of *sodium acetate R* in *water R*. Add 14.0 mL of 2 M acetic acid and dilute to 1000.0 mL with *water R*.

— *Acetate buffer solution pH 5.5.* Dissolve 5.98 g of *sodium acetate R* in *water R*. Add 3.0 mL of 2 M acetic acid and dilute to 1000.0 mL with *water R*.

— *Acetate buffer solution pH 5.8.* Dissolve 6.23 g of *sodium acetate R* in *water R*. Add 2.1 mL of 2 M acetic acid and dilute to 1000.0 mL with *water R*.

Phosphate buffer solutions

For preparing buffers with the pH values indicated in Table 5.17.1.-3, mix 250.0 mL of *0.2 M potassium dihydrogen phosphate R* and the specified volume of *0.2 M sodium hydroxide*, and dilute to 1000.0 mL with *water R*.

Table 5.17.1.-3. – *Phosphate buffer solutions*

pH	5.8	6.0	6.2	6.4	6.6	6.8
NaOH (mL)	18.0	28.0	40.5	58.0	82.0	112.0
pH	7.0	7.2	7.4	7.6	7.8	8.0
NaOH (mL)	145.5	173.5	195.5	212.0	222.5	230.5

Other phosphate buffer solutions

— *Phosphate buffer solution pH 4.5.* Dissolve 13.61 g of *potassium dihydrogen phosphate R* in 750 mL of *water R*. Adjust the pH if necessary with *0.1 M sodium hydroxide* or with *0.1 M hydrochloric acid*. Dilute to 1000.0 mL with *water R*.

— *Phosphate buffer solution pH 5.5 R.*

— Phosphate buffer solution pH 6.8 R1.

— *Buffer solution pH 7.2 R.*

— *0.33 M phosphate buffer solution pH 7.5 R.*

Simulated intestinal fluid pH 6.8

Mix 77.0 mL of *0.2 M sodium hydroxide*, 250.0 mL of a solution containing 6.8 g of *potassium dihydrogen phosphate R*, and 500 mL of *water R*. Add 10.0 g of *pancreas powder R*, mix and adjust the pH if necessary. Dilute to 1000.0 mL with *water R*.

Simulated gastric fluid

Dissolve 2.0 g of *sodium chloride R* and 3.2 g of *pepsin powder R* in *water R*, add 80 mL of *1 M hydrochloric acid* and dilute to 1000.0 mL with *water R*. If required, pepsin powder may be omitted.

Increasing pH

For a test involving increasing pH, one of the following sequences may be used:

Time (h)	0 - 1	1 - 2	2 - 3	3 - 4	4 - 5	5 - 6	6 - 7	7
pH	1.0							
pH	1.2	6.8						
pH	1.2	2.5	4.5	7.0		7.5		
pH	1.5	4.5			7.2			

To achieve this pH variation, it is possible either:

— to substitute one buffer solution for another (whole substitution);

— to remove only half of the medium each time (half change method) and replace it with a buffer solution of higher pH: the initial pH is 1.2 and the second solution is phosphate buffer solution pH 7.5; or,

— to an initial solution at pH 1.5, to add a dose of a powder mixture containing *tris(hydroxymethyl)aminomethane R* and *anhydrous sodium acetate R* to obtain pH 4.5 and a second dose to obtain pH 7.2, as described below:

— *hydrochloric acid pH 1.5*: dissolve 2 g of *sodium chloride R* in *water R*, add 31.6 mL of *1 M hydrochloric acid* and dilute to 1000.0 mL with *water R*;
— *buffer solution pH 4.5*: mix 2.28 g of *tris(hydroxymethyl) aminomethane R* with 1.77 g of *anhydrous sodium acetate R*; dissolve this mixture in the hydrochloric acid pH 1.5 described above;
— *buffer solution pH 7.2*: mix 2.28 g of *tris(hydroxymethyl) aminomethane R* with 1.77 g of *anhydrous sodium acetate R*; dissolve this mixture in the buffer solution pH 4.5 described above.

The flow-through cell may be used for the continuous change of pH.

QUALIFICATION AND VALIDATION

Due to the nature of the test method, quality by design is an important qualification aspect for *in vitro* dissolution test equipment. Any irregularities such as vibration or undesired agitation by mechanical imperfections are to be avoided.

Qualification of the dissolution test equipment has to consider the dimensions and tolerances of the apparatus. Critical test parameters, such as temperature and volume of dissolution medium, rotation speed or liquid flow rate, sampling probes and procedures, have to be monitored periodically during the periods of use.

The performance of the dissolution test equipment may be monitored by testing a reference product that is sensitive to hydrodynamic conditions. Such tests may be performed periodically or continuously for comparative reasons with other laboratories.

During testing, critical inspection and observation are required. This approach is especially important to explain any outlying results.

Validation of automated systems, whether concerning the sampling and analytical part or the dissolution media preparation and test performance, has to consider accuracy, precision, and the avoidance of contamination by any dilutions, transfers, cleaning and sample or solvent preparation procedures.

EXPRESSION OF DISSOLUTION SPECIFICATIONS FOR ORAL DOSAGE FORMS

The dissolution specification is expressed in terms of the quantity (Q) of active substance dissolved in a specified time, expressed as a percentage of the content stated on the product label.

Conventional-release dosage forms

In most cases, when tested under reasonable and justified test conditions, the acceptance criteria at level S_1 are that at least 80 per cent of the active substance is released within a specified time, typically 45 min or less. This corresponds to a Q value of 75 per cent, since, as referred to in Table 2.9.3.-1, for level S_1 the individual value of each of the 6 units tested is not less than $Q + 5$ per cent, i.e. not less than 80 per cent.

Typically, a single-point acceptance criterion is sufficient to demonstrate that the majority of the active substance has been released, although in certain circumstances it may be necessary to test at additional time point(s), in order to demonstrate adequate dissolution.

Prolonged-release dosage forms

The dissolution test acceptance criteria for prolonged-release dosage forms is normally expected to consist of 3 or more points. The 1st specification point is intended to prevent unintended rapid release of the active substance ('dose dumping'). It is therefore set after a testing period corresponding to a dissolved amount typically of 20 per cent to 30 per cent. The 2nd specification point defines the dissolution pattern and so is set at around 50 per cent release. The final specification point is intended to ensure almost complete release, which is generally understood as more than 80 per cent release.

Delayed-release dosage forms

A delayed-release dosage form may release the active substance(s) fractionally or totally according to the formulation design when tested in different dissolution media, e.g. in increasing pH conditions. Dissolution specifications therefore have to be decided on a case-by-case basis.

Gastro-resistant dosage forms require at least 2 specification points in a sequential test and 2 different specifications in a parallel test. In a sequential test, the 1st specification point represents an upper limit and is set after 1 h or 2 h in acidic medium, and the 2nd after a pre-set time period of testing in an adequate buffer solution (preferably pH 6.8).

In most cases the acceptance criteria at level B_1 are that at least 80 per cent of the active substance is released. This corresponds to a Q value of 75 per cent, since, as referred to in Table 2.9.3.-4, for level B_1 the individual value of each of the 6 units tested is not less than $Q + 5$ per cent, i.e. not less than 80 per cent.

B. Dissolution

1. Dissolution Test for Tablets and Capsules (Dissolution Test for Solid Dosage Forms)[1]

(Ph. Eur. method 2.9.3)

This test is provided to determine compliance with the dissolution requirements for solid dosage forms administered orally. In this chapter, a dosage unit is defined as 1 tablet or 1 capsule or the amount specified.

APPARATUS

Apparatus 1 (Basket apparatus)

The assembly consists of the following: a vessel, which may be covered, made of glass or other inert, transparent material[2]; a motor; a drive shaft; and a cylindrical basket (stirring element). The vessel is partially immersed in a suitable water-bath of any convenient size or heated by a suitable device such as a heating jacket. The water-bath or heating device permits maintaining the temperature inside the vessel at 37 ± 0.5 °C during the test and keeping the dissolution medium in constant, smooth motion. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smoothly rotating stirring element. Apparatus that permits observation of the preparation and stirring element during the test is preferable. The vessel is cylindrical, with a hemispherical bottom and a capacity of 1 L. Its height is 160-210 mm and its inside diameter is 98-106 mm. Its sides are flanged at the top. A fitted cover may be used to retard evaporation[3]. The shaft is positioned so that its axis is not more than 2 mm at any point from the vertical axis of the vessel and rotates smoothly

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*
[2] *The materials must not sorb, react, or interfere with the preparation to be tested.*
[3] *If a cover is used, it provides sufficient openings to allow ready insertion of the thermometer and withdrawal of samples.*

and without significant wobble that could affect the results. A speed-regulating device is used that allows the shaft rotation speed to be selected and maintained at a specified rate, within ± 4 per cent.

Shaft and basket components of the stirring element are fabricated of stainless steel, type 316 or equivalent, to the specifications shown in Figure 2.9.3.-1.

A basket having a gold coating of about 2.5 µm (0.0001 inch) thick may be used. The dosage unit is placed in a dry basket at the beginning of each test. The distance between the inside bottom of the vessel and the bottom of the basket is maintained at 25 ± 2 mm during the test.

Apparatus 2 (Paddle apparatus)

Use the assembly from Apparatus 1, except that a paddle formed from a blade and a shaft is used as the stirring element. The shaft is positioned so that its axis is not more than 2 mm from the vertical axis of the vessel, at any point, and rotates smoothly without significant wobble that could affect the results. The vertical center line of the blade passes through the axis of the shaft so that the bottom of the blade is flush with the bottom of the shaft. The paddle conforms to the specifications shown in Figure 2.9.3.-2. The distance of 25 ± 2 mm between the bottom of the blade and the inside bottom of the vessel is maintained during the test.

The metallic or suitably inert, rigid blade and shaft comprise a single entity. A suitable two-part detachable design may be used provided the assembly remains firmly engaged during the test. The paddle blade and shaft may be coated with a suitable coating so as to make them inert. The dosage unit is allowed to sink to the bottom of the vessel before rotation of the blade is started. A small, loose piece of non-reactive material, such as not more than a few turns of wire helix, may be attached to dosage units that would otherwise float. An alternative sinker device is shown in Figure 2.9.3.-3. Other validated sinker devices may be used.

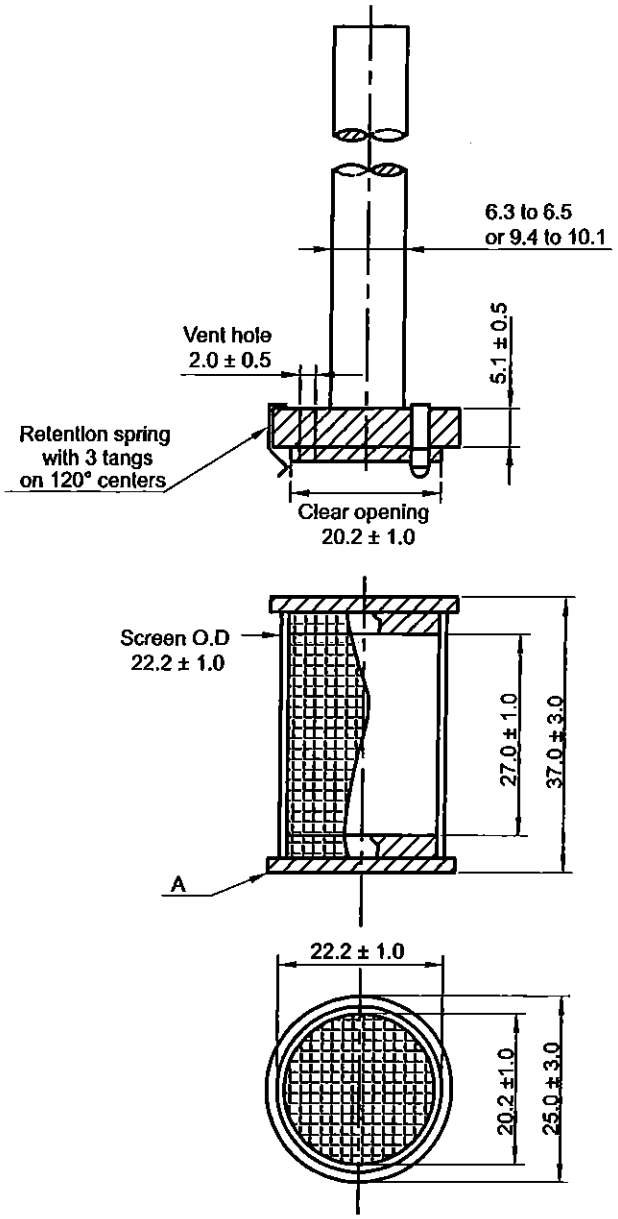
Apparatus 3 (Reciprocating cylinder)

The assembly consists of a set of cylindrical, flat-bottomed glass vessels; a set of glass reciprocating cylinders; inert fittings (stainless steel type 316 or other suitable material) and screens that are made of suitable nonsorbing and nonreactive material, and that are designed to fit the tops and bottoms of the reciprocating cylinders; a motor and drive assembly to reciprocate the cylinders vertically inside the vessels, and if desired, index the reciprocating cylinders horizontally to a different row of vessels. The vessels are partially immersed in a suitable water-bath of any convenient size that permits holding the temperature at 37 ± 0.5 °C during the test. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smooth, vertically reciprocating cylinder. A device is used that allows the reciprocation rate to be selected and maintained at the specified dip rate, within ± 5 per cent. An apparatus that permits observation of the preparations and reciprocating cylinders is preferable. The vessels are provided with an evaporation cap that remains in place for the duration of the test. The components conform to the dimensions shown in Figure 2.9.3.-4 unless otherwise specified.

Apparatus 4 (Flow-through cell)

The assembly consists of a reservoir and a pump for the dissolution medium; a flow-through cell; a water-bath that maintains the dissolution medium at 37 ± 0.5 °C. Use the specified cell size.

The pump forces the dissolution medium upwards through the flow-through cell. The pump has a delivery range

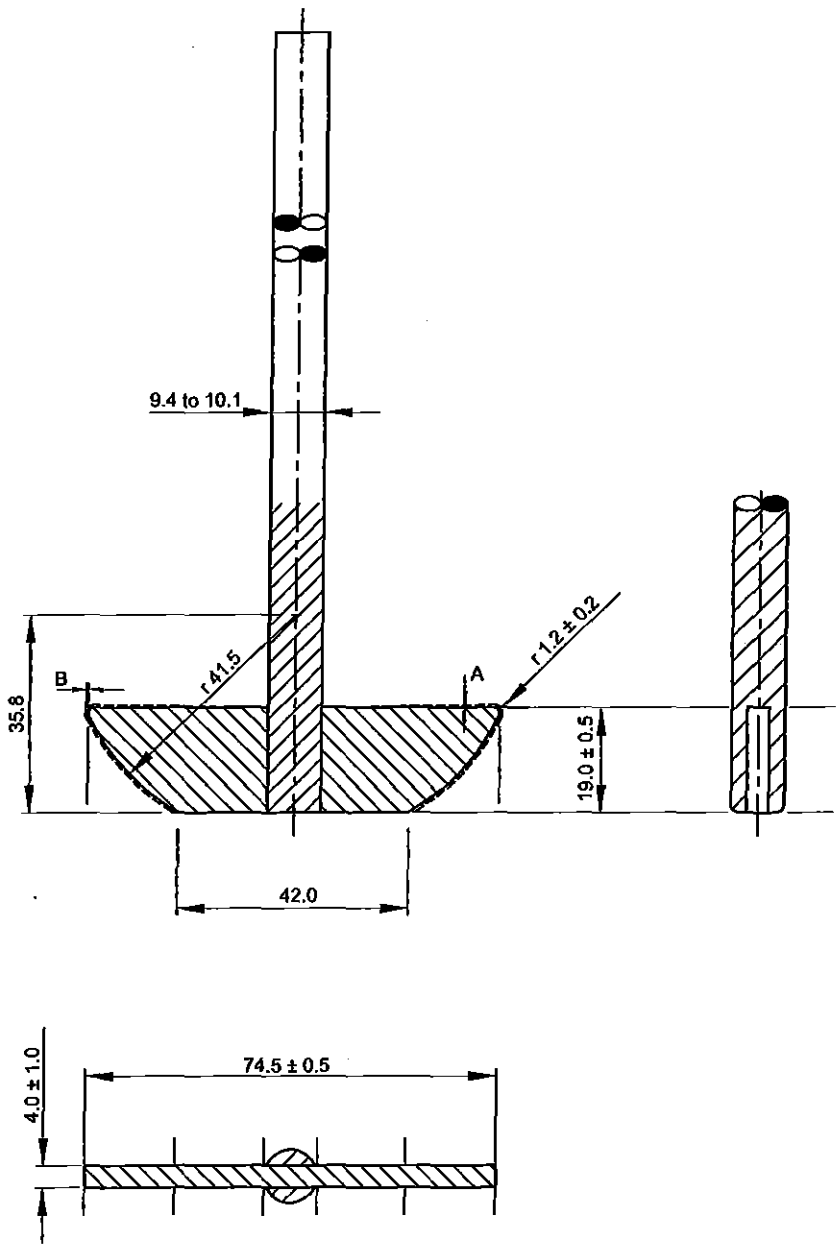


1) Screen with welded seam: 0.22-0.31 mm wire diameter with wire opening of 0.36-0.44 mm. After welding the screen may be slighty altered.
2) Maximum allowable runout at "A" is 1.0 mm when the part is rotated on center line axis with basket mounted.

Figure 2.9.3.-1. – *Apparatus 1, Basket stirring element Dimensions in millimetres*

between 240 mL/h and 960 mL/h, with standard flow rates of 4 mL/min, 8 mL/min, and 16 mL/min. It must deliver a constant flow (± 5 per cent of the nominal flow rate); the flow profile is sinusoidal with a pulsation of 120 ± 10 pulses/min. A pump without pulsation may also be used. Dissolution test procedures using the flow-through cell must be characterised with respect to rate and any pulsation.

The flow-through cell (see Figures 2.9.3.-5 and 2.9.3.-6) of transparent and inert material is mounted vertically, with a filter system that prevents escape of undissolved particles from the top of the cell; standard cell diameters are 12 mm and 22.6 mm; the bottom cone is usually filled with small glass beads of about 1 mm diameter, with 1 bead of about



A and B dimensions do not vary more than 0.5 mm when part is rotated on center line axis. Tolerances are ± 1.0 mm unless otherwise stated.

Figure 2.9.3.-2. – *Apparatus 2, Paddle stirring element*
Dimensions in millimetres

5 mm positioned at the apex to protect the fluid entry tube; a tablet holder (see Figures 2.9.3.-5 and 2.9.3.-6) is available for positioning of special dosage forms. The cell is immersed in a water-bath, and the temperature is maintained at 37 ± 0.5 °C.

The apparatus uses a clamp mechanism and 2 O-rings for the fixation of the cell assembly. The pump is separated from the dissolution unit in order to shield the latter against any vibrations originating from the pump. The position of the pump must not be on a level higher than the reservoir flasks. Tube connections are as short as possible. Use suitably inert tubing, such as polytetrafluoroethylene, with a 1.6 mm inner diameter and inert flanged-end connections.

Apparatus suitability The determination of suitability of the apparatus to perform dissolution testing must include conformance to the dimensions and tolerances of the apparatus as given above. In addition, critical test parameters that have to be monitored periodically during use include volume and temperature of the dissolution medium, rotation speed (Apparatus 1 and 2), dip rate (Apparatus 3), and flow rate of medium (Apparatus 4).

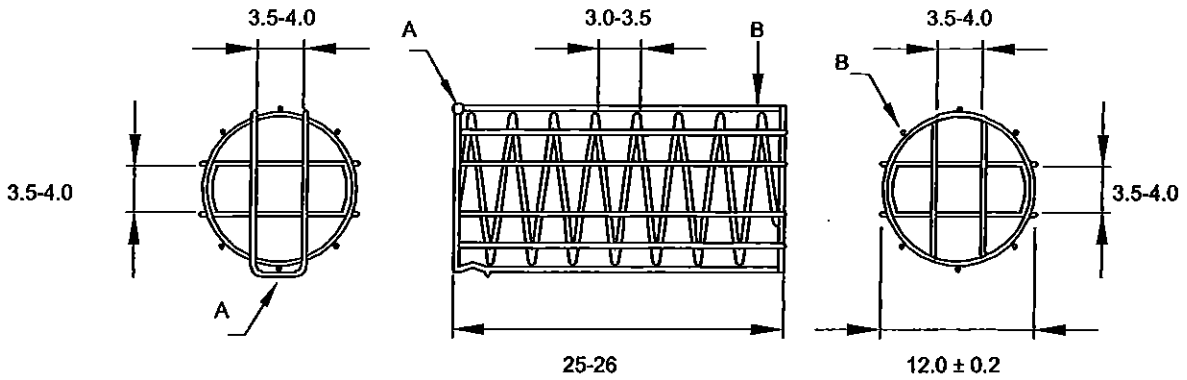
Determine the acceptable performance of the dissolution test assembly periodically.

PROCEDURE

APPARATUS 1 AND 2

Conventional-release solid dosage forms

Procedure Place the stated volume of the dissolution medium (± 1 per cent) in the vessel of the specified apparatus. Assemble the apparatus, equilibrate the dissolution



A: acid-resistant wire clasp B: acid-resistant wire support

Figure 2.9.3.-3. – *Alternative sinker*
Dimensions in millimetres

medium to 37 ± 0.5 °C, and remove the thermometer. ◊The test may also be carried out with the thermometer in place, provided it is shown that results equivalent to those obtained without the thermometer are obtained.◊

Place 1 dosage unit in the apparatus, taking care to exclude air bubbles from the surface of the dosage unit. Operate the apparatus at the specified rate. Within the time interval specified, or at each of the times stated, withdraw a specimen from a zone midway between the surface of the dissolution medium and the top of the rotating basket or blade, not less than 1 cm from the vessel wall. Where multiple sampling times are specified, replace the aliquots withdrawn for analysis with equal volumes of fresh dissolution medium at 37 °C or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered for the duration of the test and verify the temperature of the medium at suitable times. Perform the analysis using a suitable assay method[4]. Repeat the test with additional dosage units.

If automated equipment is used for sampling or the apparatus is otherwise modified, verification that the modified apparatus will produce results equivalent to those obtained with the apparatus described in this chapter, is necessary.

Dissolution medium A suitable dissolution medium is used. The volume specified refers to measurements made between 20 °C and 25 °C. If the dissolution medium is a buffered solution, adjust the solution so that its pH is within 0.05 units of the specified pH. Dissolved gases can cause bubbles to form, which may change the results of the test. In such cases, dissolved gases must be removed prior to testing[5].

Time Where a single time specification is given, the test may be concluded in a shorter period if the requirement for minimum amount dissolved is met. Samples are to be withdrawn only at the stated times, within a tolerance of ± 2 per cent.

Prolonged-release solid dosage forms

Procedure Proceed as described for conventional-release dosage forms.

Dissolution medium Proceed as described for conventional-release dosage forms.

Time The test-time points, generally 3, are expressed in hours.

Delayed-release solid dosage forms

Procedure Use Method A or Method B.

Method A

— *Acid stage.* Place 750 mL of *0.1 M hydrochloric acid* in the vessel, and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5 °C. Place 1 dosage unit in the apparatus, cover the vessel and operate the apparatus at the specified rate. After 2 h of operation in *0.1 M hydrochloric acid*, withdraw an aliquot of the fluid and proceed immediately as directed under Buffer stage. Perform an analysis of the aliquot using a suitable assay method.

— *Buffer stage.* Complete the operations of adding the buffer and adjusting the pH within 5 min. With the apparatus operating at the rate specified, add to the fluid in the vessel 250 mL of a 0.20 M solution of *trisodium phosphate dodecahydrate R* that has been equilibrated to 37 ± 0.5 °C. Adjust, if necessary, with *2 M hydrochloric acid R* or *2 M sodium hydroxide R* to a pH of 6.8 ± 0.05. Continue to operate the apparatus for 45 min, or for the specified time. At the end of the time period, withdraw an aliquot of the fluid and perform the analysis using a suitable assay method.

Method B

— *Acid Stage.* Place 1000 mL of *0.1 M hydrochloric acid* in the vessel and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5 °C. Place 1 dosage unit in the apparatus, cover the vessel, and operate the apparatus at the specified rate. After 2 h of operation in *0.1 M hydrochloric acid*, withdraw an aliquot of the fluid, and proceed immediately as directed under Buffer stage. Perform an analysis of the aliquot using a suitable assay method.

— *Buffer stage.* For this stage of the procedure use buffer that has previously been equilibrated to a temperature of

[4] *Test specimens are filtered immediately upon sampling unless filtration is demonstrated to be unnecessary. Use an inert filter that does not cause adsorption of the active substance or contain extractable substances that would interfere with the analysis.*

[5] *A method of deaeration is as follows: heat the medium, while stirring gently, to about 41 °C, immediately filter under vacuum using a filter having a porosity of 0.45 µm or less, with vigorous stirring, and continue stirring under vacuum for about 5 min. Other validated deaeration techniques for removal of dissolved gases may be used.*

37 ± 0.5 °C. Drain the acid from the vessel and add 1000 mL of pH 6.8 phosphate buffer, prepared by mixing 3 volumes of *0.1 M hydrochloric acid* with 1 volume of a 0.20 M solution of *trisodium phosphate dodecahydrate R* and adjusting, if necessary, with *2 M hydrochloric acid R* or *2 M sodium hydroxide R* to a pH of 6.8 ± 0.05. This may also be accomplished by removing from the apparatus the vessel containing the acid and replacing it with another vessel, containing the buffer and transferring the dosage unit to the vessel containing the buffer. Continue to operate the apparatus for 45 min, or for the specified time. At the end of the time period, withdraw an aliquot of the fluid and perform the analysis using a suitable assay method.

Time All test times stated are to be observed within a tolerance of ± 2 per cent, unless otherwise specified.

APPARATUS 3

Conventional-release solid dosage forms

Procedure Place the stated volume of the dissolution medium (± 1 per cent) in each vessel of the apparatus. Assemble the apparatus, equilibrate the dissolution medium to 37 ± 0.5 °C, and remove the thermometer. Place 1 dosage unit in each of the reciprocating cylinders, taking care to exclude air bubbles from the surface of each dosage unit, and immediately operate the apparatus as specified. During the upward and downward stroke, the reciprocating cylinder moves through a total distance of 9.9-10.1 cm. Within the time interval specified, or at each of the times stated, raise the reciprocating cylinders and withdraw a portion of the medium from a zone midway between the surface of the dissolution medium and the bottom of each vessel. Perform the analysis as directed. If necessary, repeat the test with additional dosage units.

Replace the aliquot withdrawn for analysis with equal volumes of fresh dissolution medium at 37 °C or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered with the evaporation cap for the duration of the test and verify the temperature of the medium at suitable times.

Dissolution medium Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

Time Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

Prolonged-release dosage forms

Procedure Proceed as described for conventional-release dosage forms under Apparatus 3.

Dissolution medium Proceed as described for prolonged-release dosage forms under Apparatus 1 and 2.

Time Proceed as described for prolonged-release dosage forms under Apparatus 1 and 2.

Delayed-release dosage forms

Procedure Proceed as described for delayed-release dosage forms, Method B, under Apparatus 1 and 2, using one row of vessels for the acid stage media and the following row of vessels for the buffer stage media, and using the volume of medium specified (usually 300 mL).

Time Proceed as directed for delayed-release dosage forms under Apparatus 1 and 2.

APPARATUS 4

Conventional-release dosage forms

Procedure Place the glass beads into the cell specified. Place 1 dosage unit on top of the beads or, if specified, on a

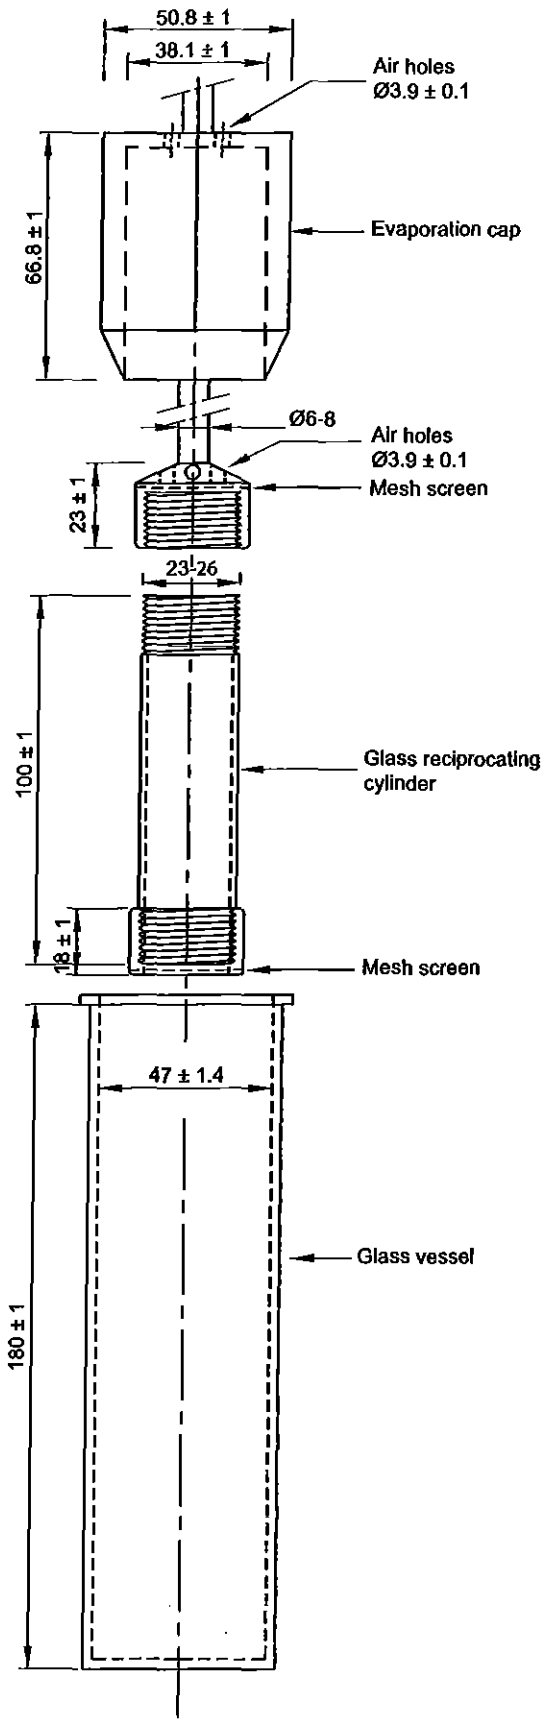


Figure 2.9.3.-4. – *Apparatus 3, glass vessel and reciprocating cylinder*

Dimensions in millimetres

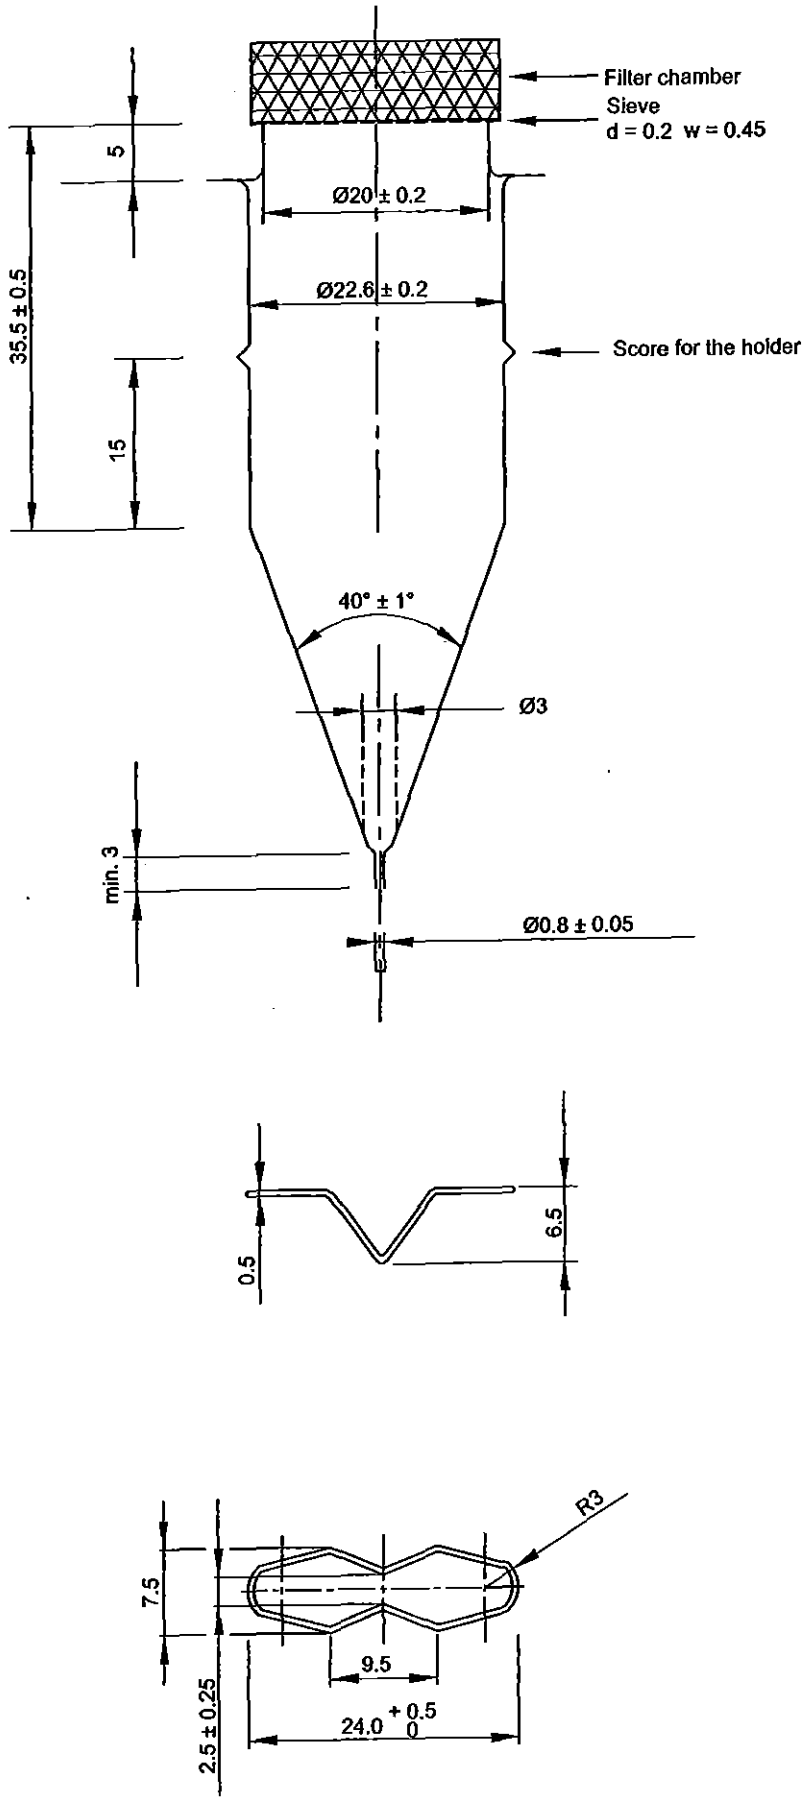

Figure 2.9.3.-5. – *Apparatus 4, large cell for tablets and capsules (top), tablet holder for the large cell (bottom)*

wire carrier. Assemble the filter head and fix the parts together by means of a suitable clamping device. Introduce by the pump the dissolution medium warmed to 37 ± 0.5 °C through the bottom of the cell to obtain the flow rate specified and measured with an accuracy of 5 per cent. Collect the eluate by fractions at each of the times stated. Perform the analysis as directed. Repeat the test with additional dosage units.

Dissolution medium Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

Time Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

Prolonged-release dosage forms

Procedure Proceed as described for conventional-release dosage forms under Apparatus 4.

Dissolution medium Proceed as described for conventional-release dosage forms under Apparatus 4.

Time Proceed as described for conventional-release dosage forms under Apparatus 4.

Delayed-release dosage forms

Procedure Proceed as described for delayed-release dosage forms under Apparatus 1 and 2, using the specified media.

Time Proceed as described for delayed-release dosage forms under Apparatus 1 and 2.

INTERPRETATION

Conventional-release solid dosage forms

Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the dosage units tested conform to Table 2.9.3.-1. Continue testing through the 3 levels unless the results conform at either S_1 or S_2. The quantity Q, is the specified amount of dissolved active substance, expressed as a percentage of the labelled content; the 5 per cent, 15 per cent, and 25 per cent values in the Table are percentages of the labelled content so that these values and Q are in the same terms.

Table 2.9.3.-1

Level	Number tested	Acceptance criteria
S_1	6	Each unit is not less than $Q + 5$ per cent.
S_2	6	Average of 12 units ($S_1 + S_2$) is equal to or greater than Q, and no unit is less than $Q - 15$ per cent.
S_3	12	Average of 24 units ($S_1 + S_2 + S_3$) is equal to or greater than Q, not more than 2 units are less than $Q - 15$ per cent, and no is less than $Q - 25$ per cent.

Prolonged-release dosage forms

Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the dosage units tested conform to Table 2.9.3.-2. Continue testing through the 3 levels unless the results conform at either L_1 or L_2. Limits on the amounts of active substance dissolved are expressed in terms of the percentage of labelled content. The limits embrace each value of Q_i, the amount dissolved at each specified fractional dosing interval. Where more than one range is specified, the acceptance criteria apply individually to each range.

Table 2.9.3.-2

Level	Number tested	Acceptance criteria
L_1	6	No individual value lies outside each of the stated ranges and no individual value is less than the stated amount at the final test time.
L_2	6	The average value of the 12 units ($L_1 + L_2$) lies within each of the stated ranges and is not less than the stated amount at the final test time; none is more than 10 per cent of labelled content outside each of the stated ranges; and none is more than 10 per cent of labelled content below the stated amount at the final test time.
L_3	12	The average value of the 24 units ($L_1 + L_2 + L_3$) lies within each of the stated ranges, and is not less than the stated amount at the final test time; not more than 2 of the 24 units are more than 10 per cent of labelled content outside each of the stated ranges; not more than 2 of the 24 units are more than 10 per cent of labelled content below the stated amount at the final test time; and none of the units is more than 20 per cent of labelled content outside each of the stated ranges or more than 20 per cent of labelled content below the stated amount at the final test time.

Delayed-release dosage forms

Acid stage Unless otherwise specified, the requirements of this portion of the test are met if the quantities, based on the percentage of the labelled content of active substance dissolved from the units tested conform to Table 2.9.3.-3. Continue testing through the 3 levels unless the results of both acid and buffer stages conform at an earlier level.

Table 2.9.3.-3

Level	Number tested	Acceptance criteria
A_1	6	No individual value exceeds 10 per cent dissolved.
A_2	6	The average value of the 12 units ($A_1 + A_2$) is not more than 10 per cent dissolved, and no individual unit is greater than 25 per cent dissolved.
A_3	12	The average value of the 24 units ($A_1 + A_2 + A_3$) is not more than 10 per cent dissolved, and no individual unit is greater than 25 per cent dissolved.

Buffer stage Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the units tested conform to Table 2.9.3.-4. Continue testing through the 3 levels unless the results of both stages conform at an earlier level. The value of Q in Table 2.9.3.-4 is 75 per cent dissolved unless otherwise specified. The quantity, Q, is the specified total amount of active substance dissolved in both the acid and buffer stages, expressed as a percentage of the labelled content. The 5 per cent, 15 per cent and 25 per cent values in the Table are percentages of the labelled content so that these values and Q are in the same terms.

Table 2.9.3.-4

Level	Number tested	Acceptance criteria
B_1	6	No unit is less than $Q + 5$ per cent.
B_2	6	The average value of the 12 units ($B_1 + B_2$) is equal to or greater than Q, and no unit is less than $Q - 15$ per cent.
B_3	12	The average value of the 24 units ($B_1 + B_2 + B_3$) is equal to or greater than Q, not more than 2 units are less than $Q - 15$ per cent, and no unit is less than $Q - 25$ per cent.

Recommendations on dissolution testing are given in general chapter 5.17.1.

2. Dissolution Test for Patches

(Ph. Eur. method 2.9.4)

This test is used to determine the dissolution rate of the active substance(s) of patches.

The disk assembly method, the cell method or the rotating cylinder method may be used, as suitable, according to the composition, dimensions and shape of the patch.

A membrane may be used for the purpose of the test. The membrane material (inert porous cellulose, silicone, etc.) must not affect the release kinetics of the active substance(s) from the patch. It must also be free of substances that may interfere with the performance of the patch (e.g. grease). The membrane may be suitably treated before the tests, for example by maintaining it for 24 h in the medium to be used in the test. The membrane is applied over the release surface of the patch in such a way as to avoid the formation of air bubbles.

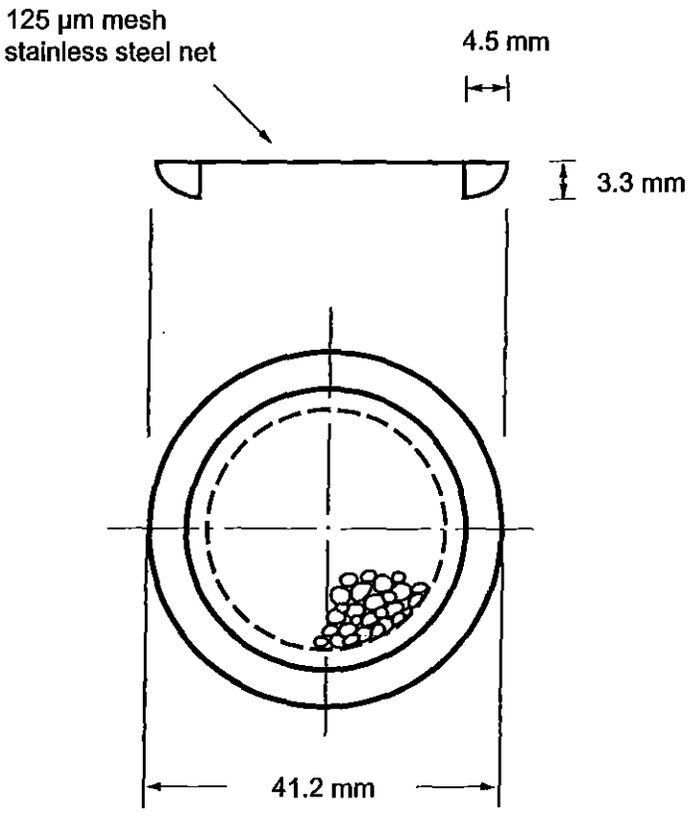

Figure 2.9.4.-1. – *Disk assembly*

1. DISK ASSEMBLY METHOD

Equipment

Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*) with the addition of a stainless steel disk assembly (SSDA) in the form of a net with an aperture of 125 µm (see Figure 2.9.4.-1).

The SSDA holds the system at the bottom of the vessel and is designed to minimise any dead volume between the SSDA and the bottom of the vessel. The SSDA holds the patch flat, with the release surface facing upwards and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm between the bottom of the paddle blade and the surface of the SSDA is maintained during the test (see Figure 2.9.4.-2). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

Procedure

Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Apply the patch to the SSDA, ensuring that the release surface is as flat as possible. The patch may be attached to the SSDA by a prescribed adhesive or by a strip of a double-sided adhesive tape. The adhesive or tape are previously tested for the absence of interference with the assay and of adsorption of the active substance(s). Press the patch, release surface facing upwards, onto the side of the SSDA made adhesive. The applied patch must not overlap the borders of the SSDA. For this purpose and provided that the preparation is homogeneous and uniformly spread on the backing layer, an appropriate and exactly measured piece of the patch may be cut and used to test the dissolution rate. This procedure may also be necessary to achieve appropriate sink conditions. This procedure must not be applied to membrane-type patches. Place the patch mounted on the

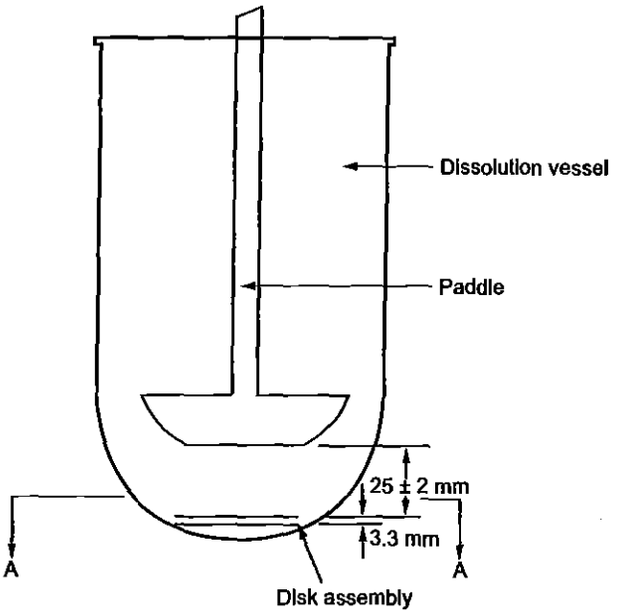

Figure 2.9.4.-2. – *Paddle and disk*

SSDA flat at the bottom of the vessel with the release surface facing upwards. Immediately rotate the paddle, at 100 r/min for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the paddle blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

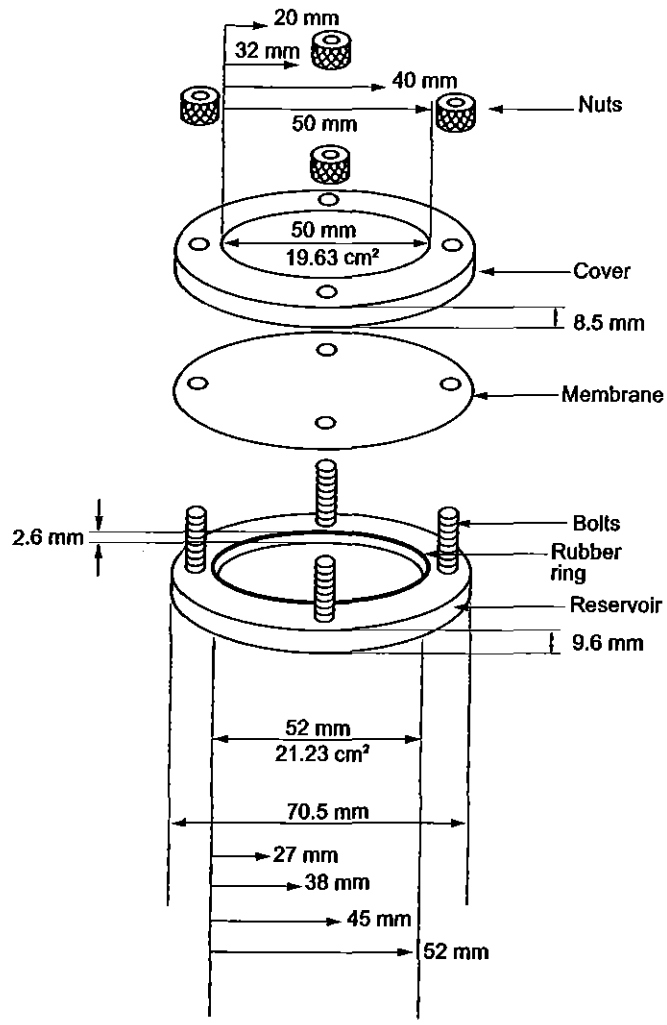

Figure 2.9.4.-3. – *Extraction cell*

2. CELL METHOD

Equipment

Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*) with the addition of the extraction cell (*cell*).

The *cell* is made of chemically inert materials and consists of a *support*, a *cover* and, if necessary, a membrane placed on the patch to isolate it from the medium that may modify or adversely affect the physico-chemical properties of the patch (see Figure 2.9.4.-3).

Support The central part of the support forms a cavity intended to hold the patch. The cavity has a depth of 2.6 mm and a diameter that is appropriate for the size of the patch to be examined. The following diameters can be used: 27 mm, 38 mm, 45 mm, 52 mm, corresponding to volumes of 1.49 mL, 2.95 mL, 4.14 mL, 5.52 mL, respectively.

Cover The cover has a central opening with a diameter selected according to the size of the patch to be examined. The patch can thus be precisely centred, and its release surface limited. The following diameters may be used: 20 mm, 32 mm, 40 mm, 50 mm corresponding to areas of 3.14 cm^2, 8.04 cm^2, 12.57 cm^2, 19.63 cm^2, respectively. The cover is held in place by nuts screwed onto bolts projecting from the support. The cover is sealed to the support by a rubber ring set on the reservoir.

Extraction cell The *cell* holds the patch flat, with the release surface facing upwards and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm is maintained between the lower surface of the paddle blade and the upper surface of the cell (see Figure 2.9.4.-4). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

Procedure

Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Precisely centre the patch in the *cell* with the release surface facing upwards. Close the *cell*, if necessary applying a hydrophobic substance (for example, petrolatum) to the flat surfaces to ensure the seal, and ensure that the patch stays in place. Introduce the *cell* flat into the bottom of the vessel with the cover facing upwards. Immediately rotate the paddle, at 100 r/min for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the paddle blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

3. ROTATING CYLINDER METHOD

Equipment

Use the assembly of the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*). Replace the paddle and shaft with a stainless steel cylinder stirring

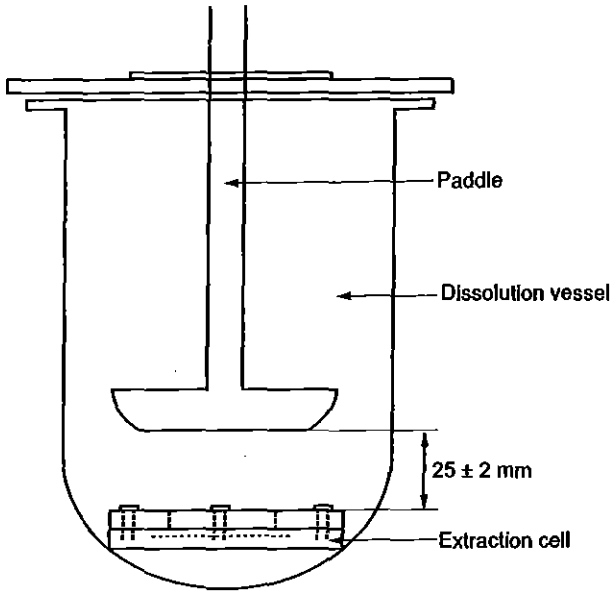

Figure 2.9.4.-4. – *Paddle over extraction cell*

element (*cylinder*) (see Figure 2.9.4.-5). The patch is placed on the *cylinder* at the beginning of each test. The distance between the inside bottom of the vessel and the *cylinder* is maintained at 25 ± 2 mm during the test. The temperature is maintained at 32 ± 0.5 °C. The vessel is covered during the test to minimise evaporation.

Procedure

Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Remove the protective liner from the patch and place the adhesive side on a piece of suitable inert porous membrane that is at least 1 cm larger on all sides than the patch. Place the patch on a clean surface with the membrane in contact with this surface. Two systems for adhesion to the *cylinder* may be used:

— apply a suitable adhesive to the exposed membrane borders and, if necessary, to the back of the patch;
— apply a double-sided adhesive tape to the external wall of the *cylinder*.

Using gentle pressure, carefully apply the non-adhesive side of the patch to the *cylinder*, so that the release surface is in contact with the dissolution medium and the long axis of the patch fits around the circumference of the *cylinder*.

The system for adhesion used is previously tested for absence of interference with the assay and of adsorption of the active substance(s).

Place the *cylinder* in the apparatus and immediately rotate the *cylinder*, at 100 r/min for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the rotating *cylinder*, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume withdrawn, as necessary. Repeat the test with additional patches.

4. INTERPRETATION

The requirements are met if the quantity of active substance(s) released from the patch, expressed as the amount per surface area per time unit, is within the prescribed limits at the defined sampling times.

3. Dissolution Test for Lipophilic Solid Doseage Forms

(Ph. Eur. method 2.9.42)

APPARATUS

The apparatus (see Figure 2.9.42.-1) consists of:

— A reservoir for the dissolution medium.
— A pump that forces the dissolution medium upwards through the flow-through cell.
— A flow-through cell shown in Figure 2.9.42.-2 specifically intended for lipophilic solid dosage forms such as suppositories and soft capsules. It consists of 3 transparent parts which fit into each other. The lower part (1) is made up of 2 adjacent chambers connected to an overflow device.

The dissolution medium passes through chamber A and is subjected to an upwards flow. The flow in chamber B is downwards directed to a small-size bore exit which leads upwards to a filter assembly. The middle part (2) of the cell has a cavity designed to collect lipophilic excipients which float on the dissolution medium. A metal grill serves as a rough filter. The upper part (3) holds a filter unit for paper, glass fibre or cellulose filters.

— A water-bath that will maintain the dissolution medium at 37 ± 0.5 °C.

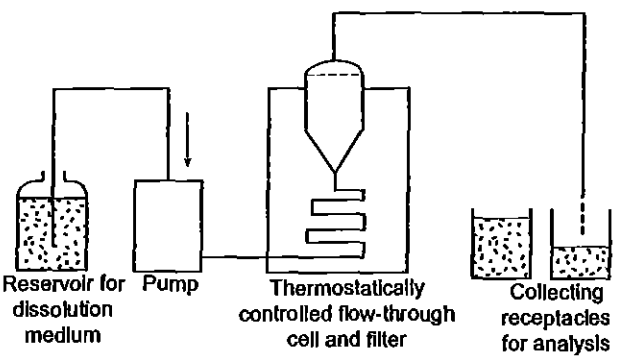

Figure 2.9.42.-1. – *Flow-through apparatus*

Dissolution medium

If the dissolution medium is buffered, adjust its pH to within ± 0.05 units of the prescribed value. Remove any dissolved gases from the dissolution medium before the test since they can cause the formation of bubbles that significantly affect the results.

METHOD

Place 1 unit of the preparation to be examined in chamber A. Close the cell with the prepared filter assembly. At the beginning of the test, chamber A requires air removal via a small orifice connected to the filter assembly. Heat the dissolution medium to an appropriate temperature taking the melting point of the preparation into consideration. Using a suitable pump, introduce the warmed dissolution medium through the bottom of the cell to obtain a suitable continuous flow through an open or closed circuit at the prescribed rate (± 5 per cent). When the dissolution medium reaches the overflow, air starts to escape through the capillary and chamber B fills with the dissolution medium. The preparation spreads through the dissolution medium according to its physico-chemical properties.

In justified and authorised cases, representative fractions of large volume suppositories may be tested.

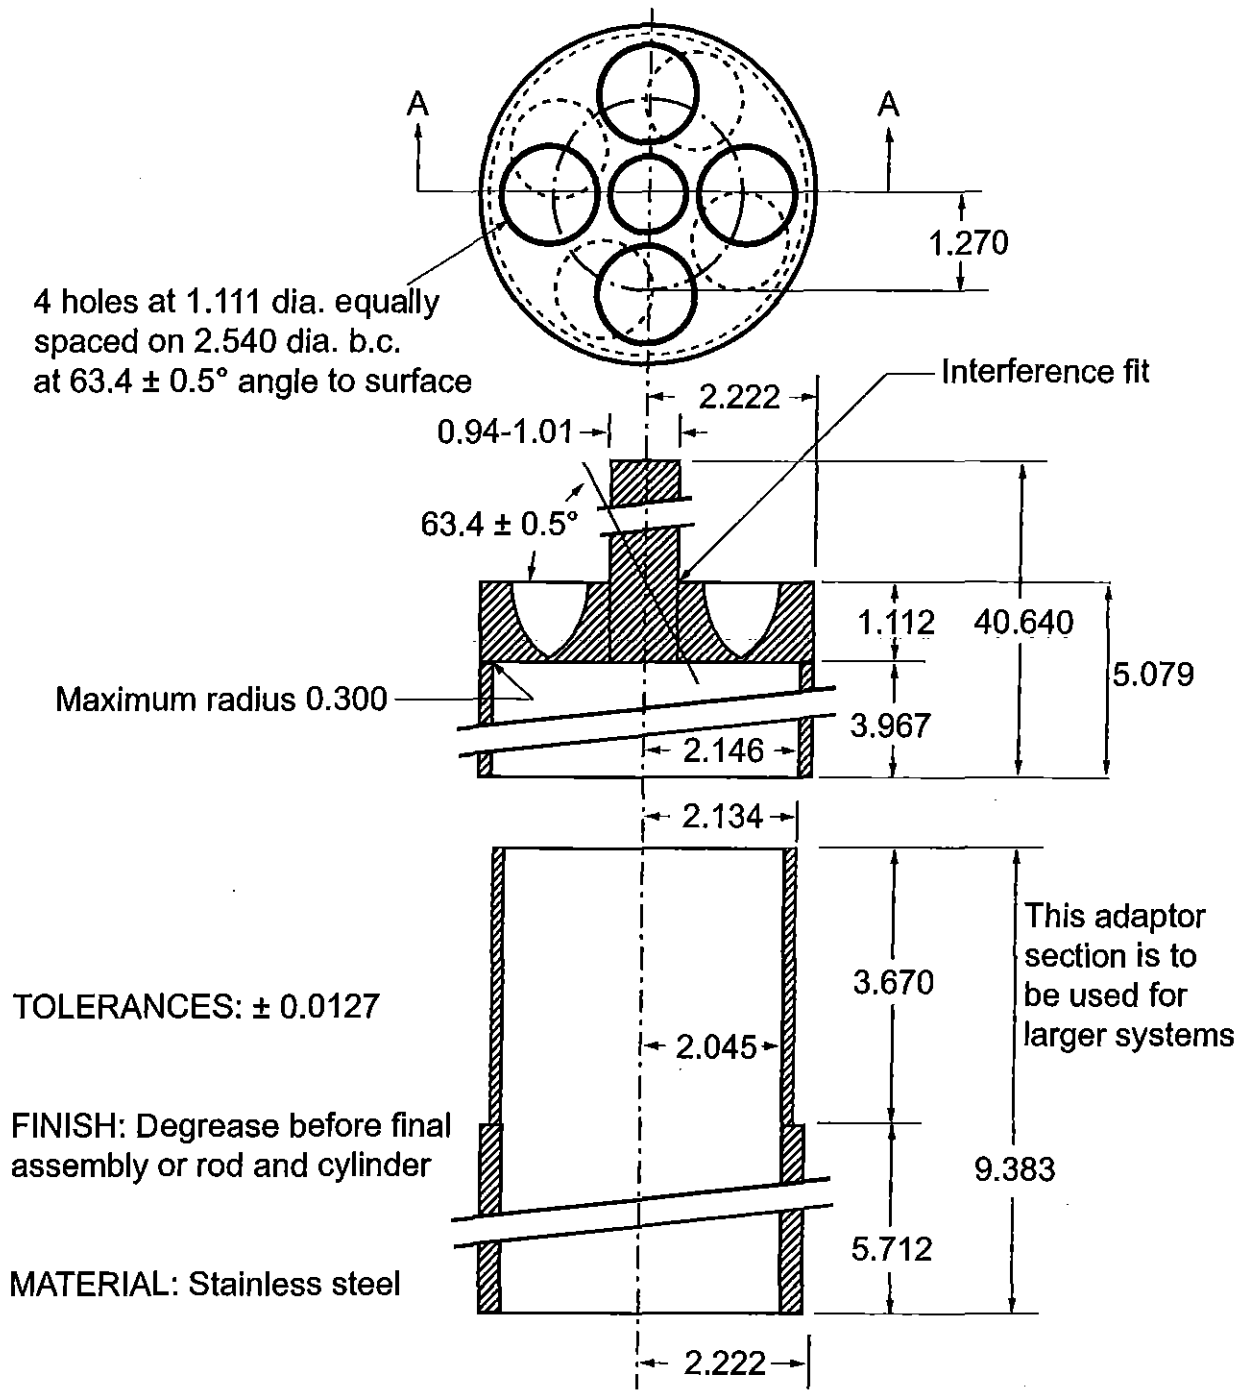

Figure 2.9.4.-5. – *Cylinder stirring element*
Dimensions in centimetres

SAMPLING AND EVALUATION

Samples are always collected at the outlet of the cell, irrespective of whether the circuit is opened or closed.

Filter the liquid removed using an inert filter of appropriate pore size that does not cause significant adsorption of the active substance from the solution and does not contain substances extractable by the dissolution medium that would interfere with the prescribed analytical method. Proceed with analysis of the filtrate as prescribed.

The quantity of the active substance dissolved in a specified time is expressed as a percentage of the content stated on the label.

4. Dissolution Test for Medicated Chewing Gum
(Ph. Eur. method 2.9.25)

PRINCIPLE

The test is used to determine the dissolution rate of active substances in medicated chewing gums. This is done by applying a mechanical kneading procedure to a piece of gum placed in a small chamber designed to simulate the process of chewing.

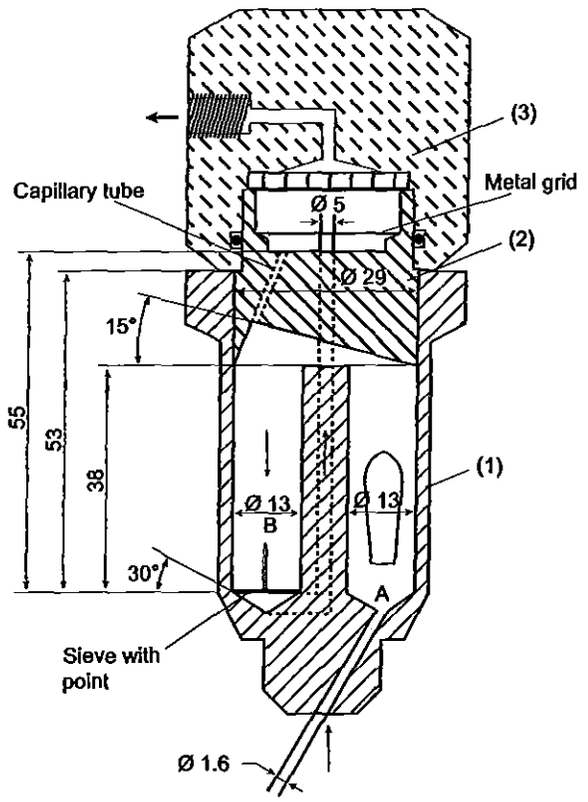

Figure 2.9.42.-2. – *Flow-through cell*
Dimensions in millimetres

APPARATUS A

Chewing apparatus A (Figure 2.9.25.-1) consists of:
— 1 chewing chamber;
— 1 vertical piston;
— 2 horizontal pistons with O-rings and sealing rings.

The chewing chamber consists of 4 individual parts:
— 1 central chamber;
— 1 funnel (Figure 2.9.25.-2);
— 2 guides with bushes (Figure 2.9.25.-3).

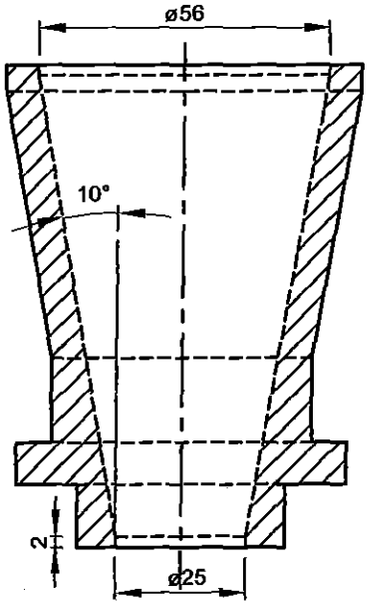

Figure 2.9.25.-2 – *Funnel*
Dimensions in millimetres

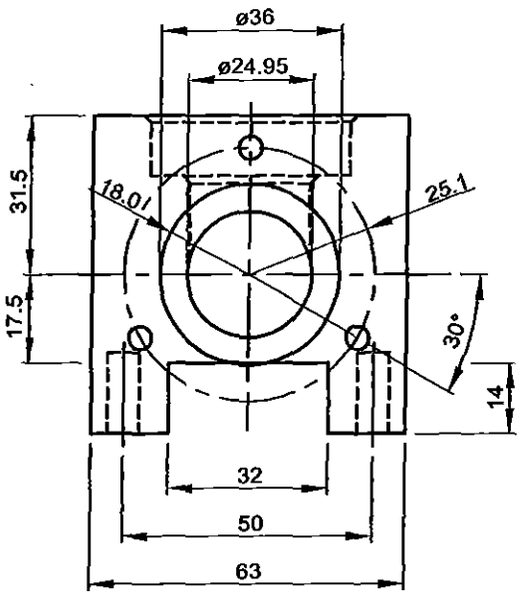

Figure 2.9.25.-3 – *Guide (section G-G)*
Dimensions in millimetres

The funnel and guides are mounted on the central chamber. The O-rings are incorporated in the piston recess with the sealing ring around it; the sealing rings ensure that the chamber is watertight. The horizontal pistons are placed in the chewing chamber through the guides.

The gum is artificially chewed by the horizontal pistons, and the vertical piston ensures that the gum stays in the right place between chews.

Machine speed is controlled to ensure a constant cycle. One cycle (chew) is defined as follows: the horizontal pistons start from their outermost position, move to their innermost position then return to their outermost position. Within one cycle, the vertical piston moves from its lowest position to its uppermost position and back to its lowest position.

Each horizontal piston has a stroke of 25.0 mm. The maximum distance between these 2 pistons is 50 mm. The minimum distance between the 2 horizontal pistons is 0.1 mm to 1.0 mm. The vertical piston has a stroke of 22.0 mm.

Horizontal piston movement is controlled so that the 2 pistons are at their innermost position at the same time. Vertical piston movement is controlled so that it does not conflict with the movement of the horizontal pistons.

If necessary, the machine can be constructed so that the horizontal pistons rotate around their own axes in opposite direction to each other by the end of the chew in order to obtain maximum chewing.

All parts of the apparatus that may come into contact with the preparation or the dissolution medium are chemically inert and do not adsorb, react with or interfere with the sample.

APPARATUS B

Chewing apparatus B (Figure 2.9.25.-4) consists of:
— 1 test cell (Figure 2.9.25.-5 or 2.9.25.-6);
— 1 vertical axle with upper chewing surface (Figures 2.9.25.-7 and 2.9.25.-8);
— 1 base chamber with lower chewing surface (Figures 2.9.25.-9 and 2.9.25.-10);
— 1 device for up-and-down chewing motion;
— 1 revolving device for the vertical axle.

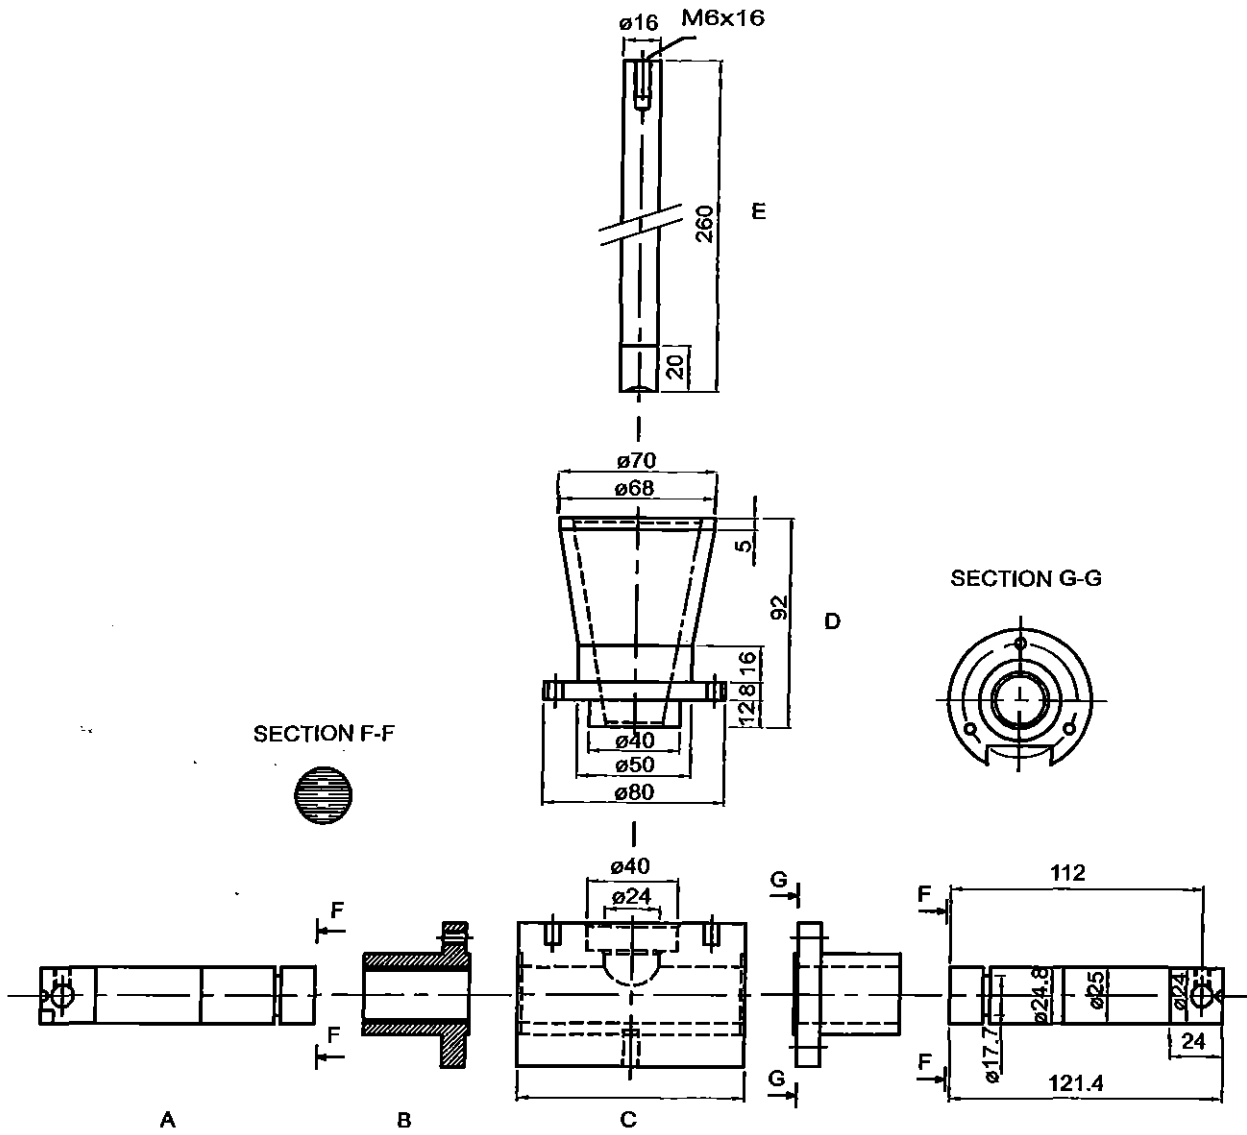

Figure 2.9.25.-1 – *Apparatus A - Chewing chamber and pistons*
Dimensions in millimetres

The gum is artificially chewed by the lower and upper chewing surfaces. Machine speed is controlled to ensure a constant cycle. The distance between the lower and upper chewing surfaces may be set up to 5 mm. The turning angle of the revolving device is about 20°.

The test cells may also be equipped with 1 or 2 glass sampling tubes, coming through the thermostatic double wall. These tubes also make it possible to have an external sink, which may be necessary to achieve sink conditions for sparingly soluble substances.

The gum is usually sandwiched between 2 circular plastic nets to prevent disintegration.

Nets made from nylon (PA6) with an aperture of 1.4 mm and a wire diameter of 0.405 mm may be used.

All parts of the apparatus that may come into contact with the preparation or the dissolution medium are chemically inert and do not adsorb, react with or interfere with the sample.

PROCEDURE

For each determination, the following information is needed:
- — apparatus used (type A or type B);
- — composition, volume and temperature of the dissolution medium;
- — number of chews per minute;
- — time and sampling method;
- — whether the analysis is performed on the gum residue or on the dissolution medium;
- — method of analysis.

Place the prescribed volume of dissolution medium in the chewing chamber, usually 20 mL of *phosphate buffer solution pH 6.0 R2*. Maintain the medium temperature at 37 ± 0.5 °C using an electrical device with external control (apparatus A) or with a thermostat (apparatus B). Set the machine speed at the prescribed number of chews per minute (typically up to 60). Accurately weigh a portion of gum or the whole gum, put it into the chewing chamber and start the machine.

C. test cell
D. axle
E. upper chewing surface
F. lower chewing surface
G. base chamber
H. device for up-and-down chewing motion

Figure 2.9.25.-4 – *Apparatus B*

SAMPLING AND EVALUATION

Stop the apparatus at the prescribed time. Remove the gum residue and take a sample of the dissolution medium. Determine the content of active substance(s) by a suitable method. Medium replacement may be made after each sampling procedure; compensation by calculation of medium volume change or sample dilution is needed. Alternatively, determine the content of active substance(s) remaining in the gum residue. Carry out the test successively on 6 medicated chewing gums.

The quantity of active substance(s) dissolved in a specified time is expressed as a percentage of the content stated on the label.

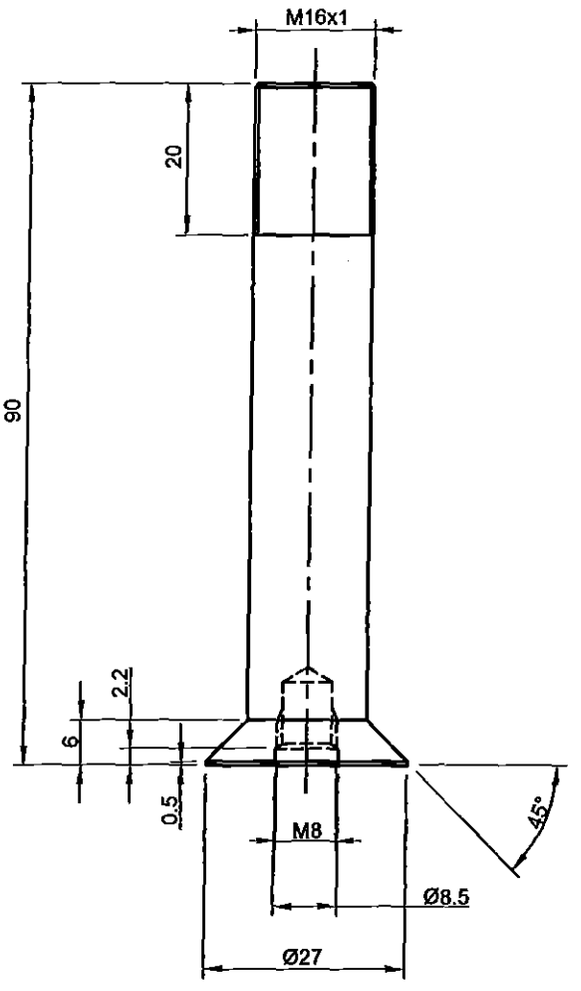

Figure 2.9.25.-7 – *Axle*
Dimensions in millimetres

5. Intrinsic Dissolution

(Ph. Eur. method 2.9.29)

The test is intended to determine the intrinsic dissolution rate of pure solid substances following compaction. It is carried out under specified experimental conditions such that a practical measure of the intrinsic dissolution rate is obtained.

The intrinsic dissolution rate is a theoretical value referring to pure solid substances having null porosity, but, practically, intrinsic dissolution rate is determined on substances having a minimal porosity.

PRINCIPLE

The intrinsic dissolution rate is defined as the dissolution rate of pure substances following compaction under the condition of constant surface area. Its assessment is useful in the characterisation of active substances and excipients.

The dissolution rate of pure substances can be affected by all the solid state properties such as crystal habit, crystallinity, amorphism, polymorphism, pseudo-polymorphism, particle size and specific surface area. In addition, it can also be influenced by extrinsic factors (test conditions), such as hydrodynamics, temperature, viscosity, pH, buffer strength and ionic strength of the dissolution medium.

The assessment of intrinsic dissolution rate of a solid substance involves the preparation of a compact. Assurance

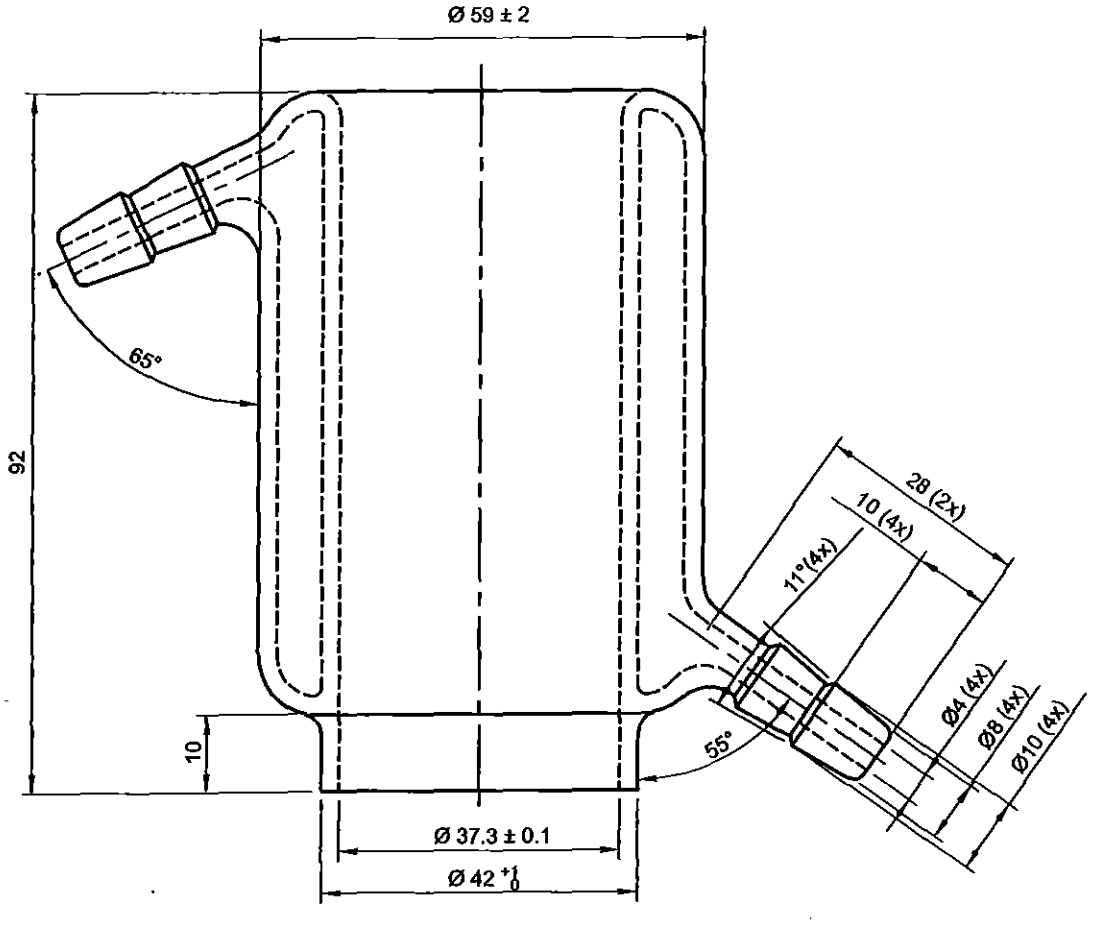

Figure 2.9.25.-5 – *Test cell*
Dimensions in millimetres

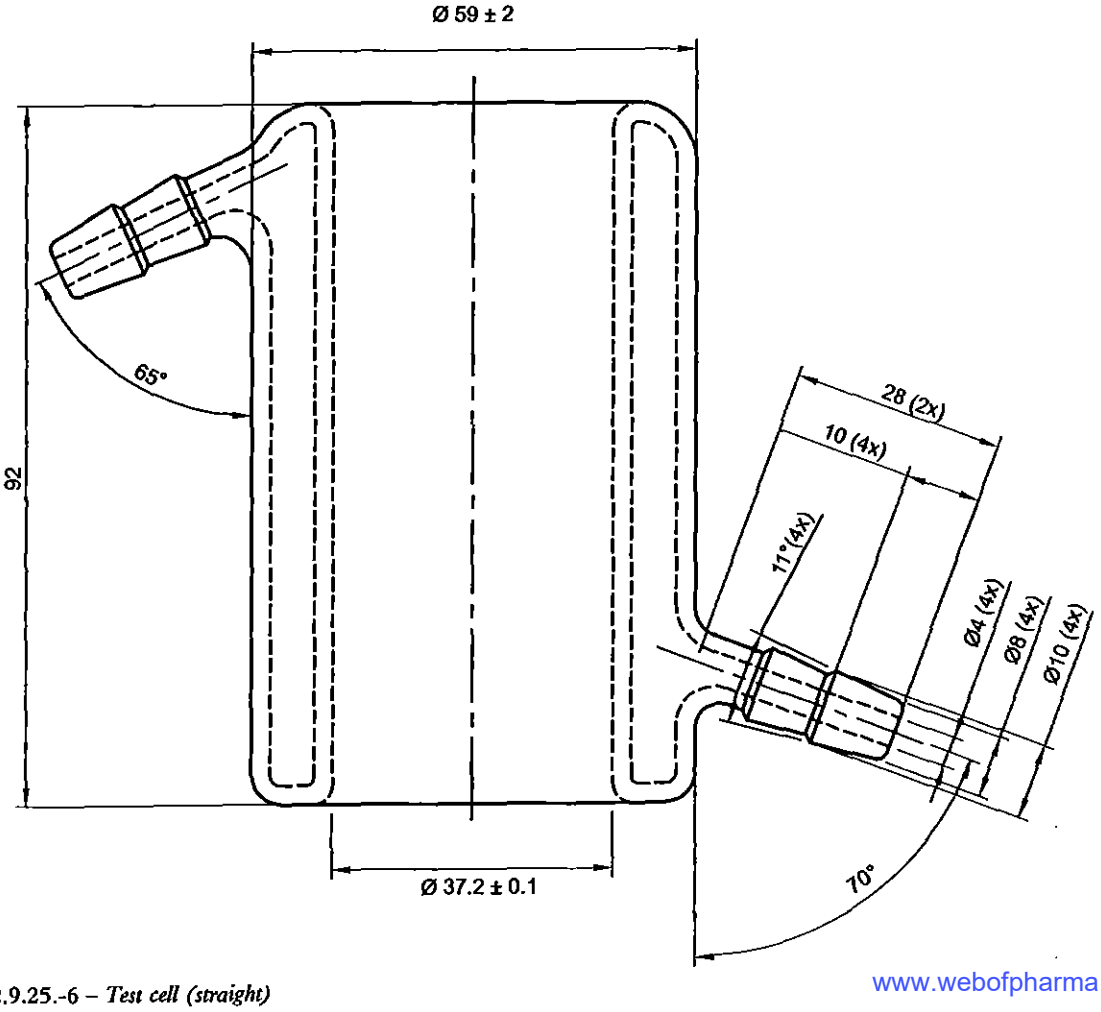

Figure 2.9.25.-6 – *Test cell (straight)*
Dimensions in millimetres

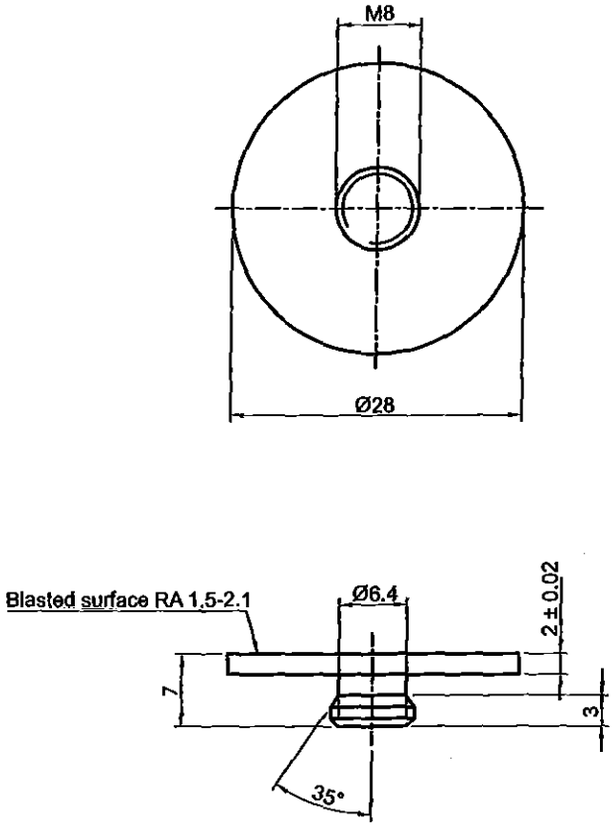

Figure 2.9.25.-8 – *Upper chewing surface*
Dimensions in millimetres

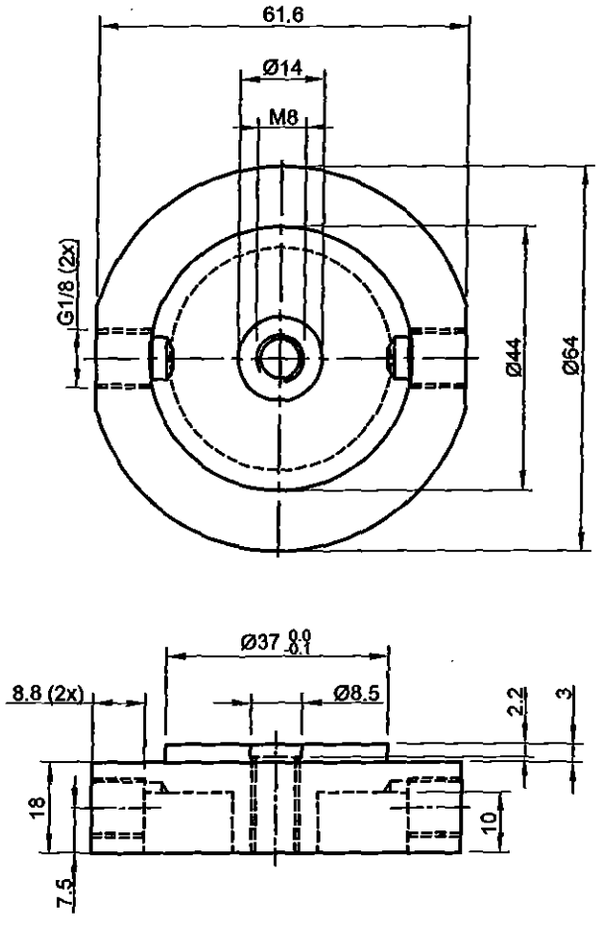

Figure 2.9.25.-9 – *Base chamber*
Dimensions in millimetres

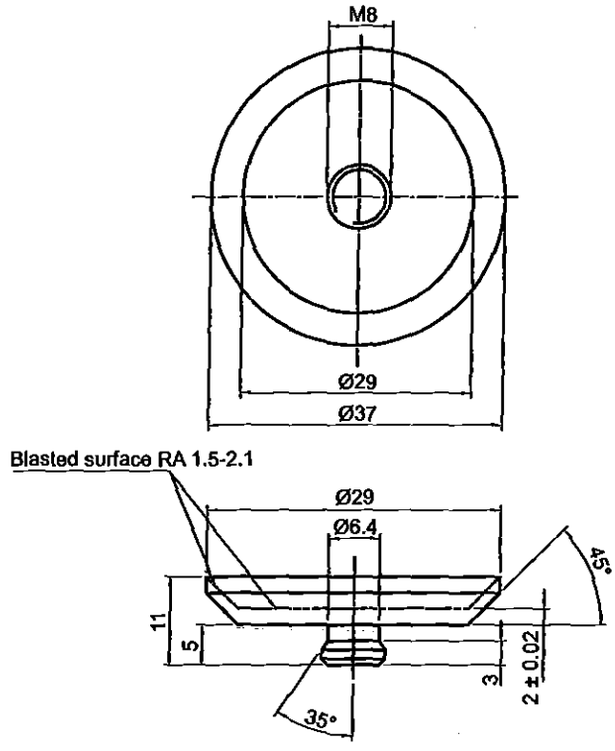

Figure 2.9.25.-10 – *Lower chewing surface*
Dimensions in millimetres

of appropriate compaction properties of the powder to be tested is needed prior to performing the test.

The intrinsic dissolution rate is determined by exposing a constant area of the compacted substance to an appropriate dissolution medium, while maintaining constant stirring rate, temperature, ionic strength and pH.

The intrinsic dissolution rate is expressed in terms of dissolved mass of substance per time per exposed area, typically in milligrams per minute per square centimetre ($mg \cdot min^{-1} \cdot cm^{-2}$).

APPARATUS

A typical apparatus consists of a punch and die fabricated out of hardened steel. The base of the die has 3 threaded holes for the attachment of a surface plate made of polished steel, providing a mirror-smooth base for the compact. The die has a 0.1-1.0 cm diameter cavity into which a measured amount of the powder to be tested is placed. The punch is then inserted in the die cavity and the material is compressed, generally using a benchtop hydraulic press. A hole through the head of the punch allows insertion of a metal rod to facilitate removal from the die after the test. A compact is formed in the cavity with a single face of defined area exposed on the bottom of the die (Figure 2.9.29.-1). The bottom of the die cavity is threaded so that at least 50-75 per cent of the compact can dissolve without falling out of the die. The top of the die has a threaded shoulder that allows it to be attached to a holder. The holder is mounted on a laboratory stirring device, and the entire die, with the compact still in place, is immersed in the dissolution medium and rotated by the stirring device.

PROCEDURE

Weigh the material onto a piece of weighing paper. Attach the surface plate to the underside of the die, and secure it with the 3 provided screws. Transfer the sample of powder tested into the die cavity. Place the punch into the chamber,

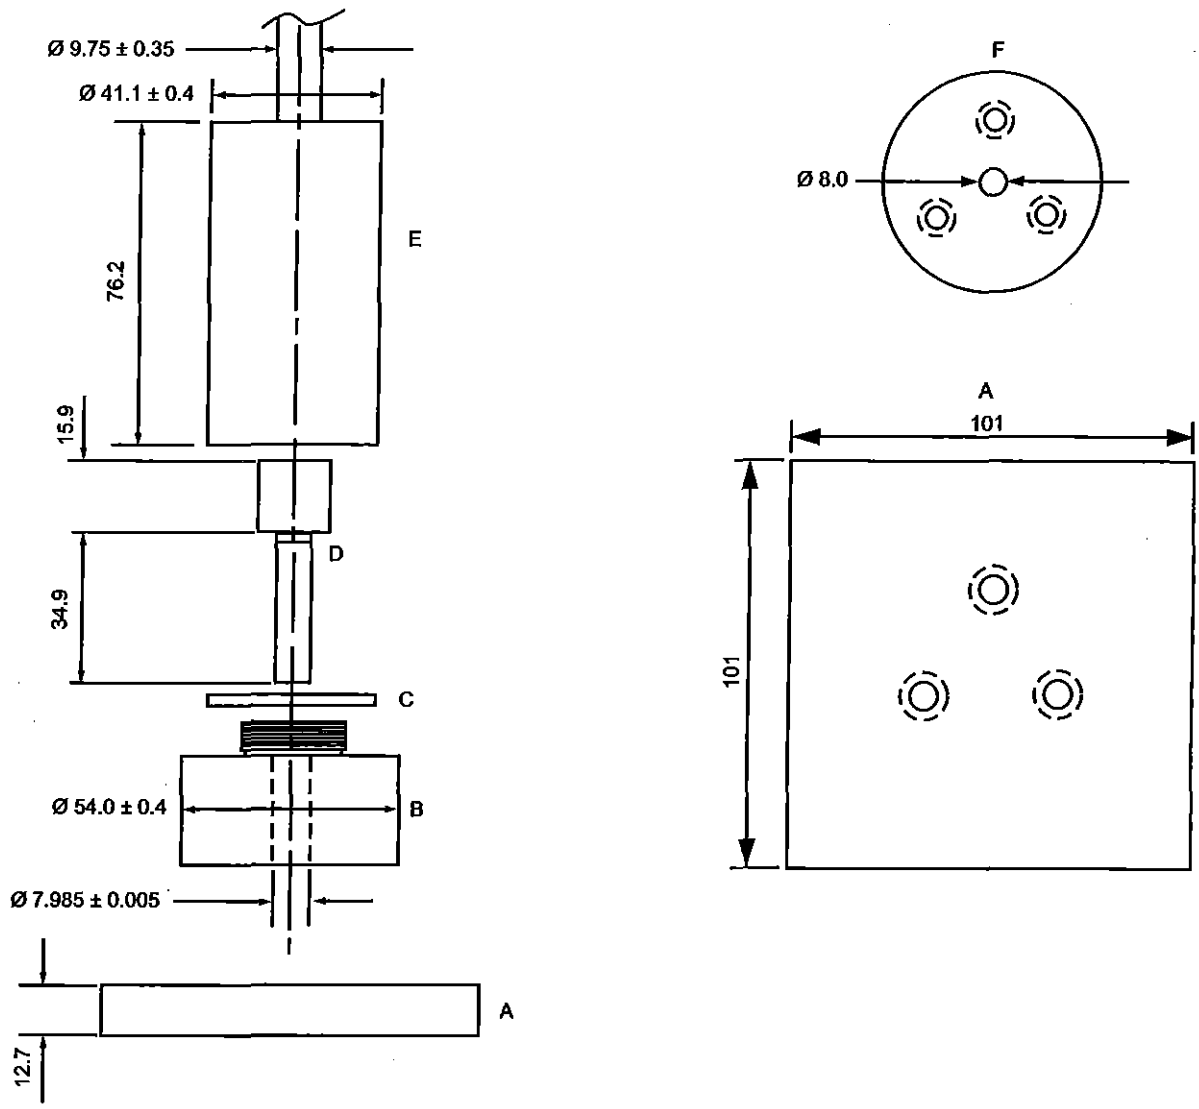

Figure 2.9.29.-1. – *Typical apparatus used to obtain the compact for the determination of the intrinsic dissolution*
Dimensions in millimetres

and secure the metal plate on the top of the assembly. Compress the powder using a hydraulic press by applying a suitable pressure for a sufficient dwell time to ensure a stable compact with minimal porosity; the disintegration of the compact has to be prevented as far as possible, since it would cause an increase in surface area and hence in dissolution rate. Detach the surface plate, and screw the die with punch still in place into the holder. Tighten securely. Remove all loose powder from the surface of the die by blowing compressed air or nitrogen across the surface of the compact.

Slide the die-holder assembly into the dissolution test chuck and tighten. Position the shaft in the spindle so that when the test head is lowered, the exposed surface of the compact will be 3.8 cm from the bottom of the vessel. The disc assembly is aligned to minimise wobble and air bubbles are not allowed to form as this could decrease the compact surface in contact with the dissolution medium. If possible, sink conditions are maintained throughout the test. However, in order to obtain detectable concentrations of solute, the use of a relatively small volume of medium may be necessary as a consequence of the limited surface available for dissolution.

Warm the dissolution medium to the temperature chosen for the test. Lower the test head into position before rotation. Care should be taken to ensure that air bubbles are excluded from the surface of the compact as this could decrease the compact surface in contact with the dissolution medium. Operate the apparatus immediately at the speed of rotation chosen for the test.

Collect samples at fixed time intervals and assay them by means of an analytical method of suitable sensitivity and accuracy.

ASSESSMENT OF THE RESULTS

The data for the cumulative amount dissolved at each time point are corrected for sampling losses. To calculate the intrinsic dissolution rate, plot the cumulative amount of sample dissolved per unit area of the compact against time. The cumulative amount dissolved per unit area is given by the cumulative amount dissolved at each time point divided by the surface area exposed. Linear regression is then performed on the normalised experimental data relevant to an appropriate time interval preceding the possible disintegration of the compact. The intrinsic dissolution rate of the substance tested, expressed in milligrams per minute per square centimetre, is determined from the slope of the regression line. The result for intrinsic dissolution rate must be accompanied by a statement of the precise conditions of compact preparation and test method (dissolution medium, volume of medium used, stirring rate, temperature etc.).

NOTE When necessary and justified, an apparatus with a different configuration may be used, such as a die holder that holds the compact in a fixed vertical position, with agitation provided by a paddle positioned at a defined distance from the surface of the compact.

6. Apparent Dissolution

(Ph. Eur. method 2.9.43)

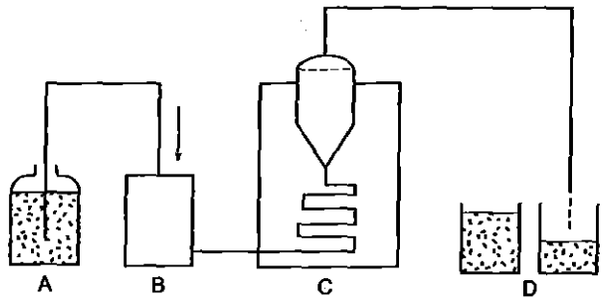
This method is mainly used to determine the apparent dissolution rate of pure solid substances. It may also be used for the determination of the apparent dissolution rate of active substances in preparations presented as powders or granules.

APPARATUS

All parts of the apparatus that may come into contact with the sample or the dissolution medium are chemically inert and do not adsorb, react with, or interfere with the test sample. No part of the assembly or its environment contributes significant motion, agitation or vibration beyond that resulting from the flow-through system.

Apparatus that permits observation of the sample is preferable.

The apparatus (see Figure 2.9.43.-1) consists of:
- a reservoir for the dissolution medium;
- a pump that forces the dissolution medium upwards through the flow-through cell;
- a flow-through cell, preferably of transparent material, mounted vertically with a filter system preventing escape of undissolved particles;
- a water-bath that will maintain the dissolution medium at the chosen temperature (generally 37 ± 0.5 °C).



A. reservoir for dissolution medium | B. pump | C. thermostatically controlled flow-through cell and filter | D. collecting vessels for analysis

Figure 2.9.43.-1. – *Flow-through apparatus*

The flow-through cell shown in Figure 2.9.43.-2 consists of 3 parts that fit into each other. The lower part supports a system of grids and filters on which the powder is placed. The middle part, which fits onto the lower part, contains an insert that sieves the sample when the dissolution medium flows through the cell. This insert is made up of 2 parts: a conical sieve that is placed on the sample and a clip placed midway down the middle part to hold the sieve in place when the dissolution medium passes through. A 2nd filtration assembly (grid and filter) is placed on top of the middle part before fitting the upper part through which the dissolution medium flows out of the cell.

DISSOLUTION MEDIUM

If the dissolution medium is buffered, adjust its pH to within ± 0.05 units. Remove any dissolved gases from the dissolution medium before the test, since they can cause the formation of bubbles, which significantly affect the results.

METHOD

Place a bead of 5 ± 0.5 mm diameter at the bottom of the cone of the lower part followed by glass beads of suitable size, preferably of 1 ± 0.1 mm diameter. Place a sieve (with 0.2 mm apertures), a suitable filter and a 2nd sieve on top of the lower part. Fit the middle part onto the lower part. Weigh the assembly. Place the sample on the filtration assembly and weigh the sample in the cell. Place the sieve of the insert, cone upwards, on the sample, and position the clip midway down the middle part. Place a sieve (with 0.2 mm apertures) and a suitable filter on top of the middle part. Fit the upper part. Heat the dissolution medium to the chosen temperature. Using a suitable pump, introduce the dissolution medium through the bottom of the cell to obtain a suitable continuous flow through an open or closed circuit at the prescribed rate ± 5 per cent.

SAMPLING

Samples of dissolution medium are collected at the outlet of the cell, irrespective of whether the circuit is opened or closed.

Immediately filter the liquid removed using an inert filter of appropriate pore size that does not cause significant adsorption of the substances from the solution and does not contain substances extractable by the dissolution medium that would interfere with the prescribed analytical method. Proceed with the analysis of the filtrate as prescribed.

ASSESSMENT OF THE RESULTS

When the test is performed for batch release purposes, an adequate number of replicates is carried out.

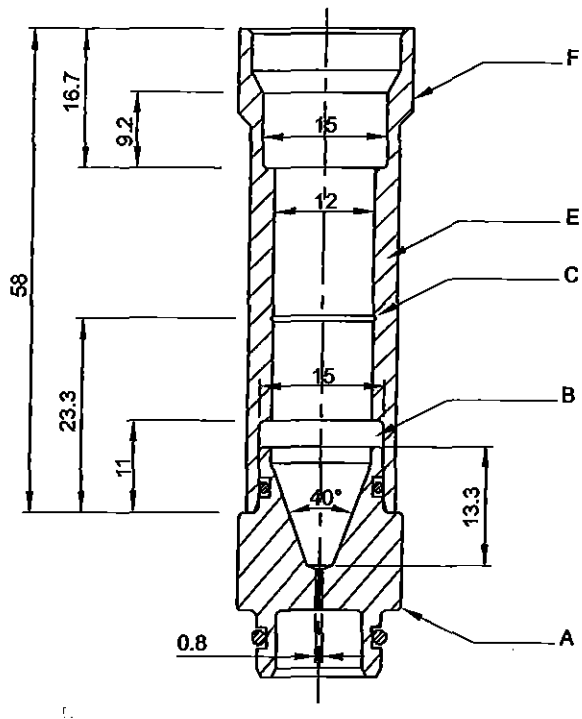
The results are expressed as:
- the amount of dissolved substance by time unit (if the dissolution is linear);
- the dissolution time of the whole sample and at appropriate intermediate stages.

Monographs of the British Pharmacopoeia

The following additional points apply to monographs of the British Pharmacopoeia.

APPARATUS

The choice of the apparatus to be used depends on the physico-chemical characteristics of the dosage form. When this Appendix is invoked in an individual tablet or capsule monograph of the British Pharmacopoeia, use Apparatus I unless otherwise directed.



A. lower part C. clip E. middle part
B. sieve D. insert F. upper part

Figure 2.9.43.-2. – *Flow-through cell*
Dimensions in millimetres

PROCEDURE

The dissolution medium is that specified in the individual monograph. Unless otherwise indicated in the monograph, withdraw samples at 45 minutes.

Where one tablet or capsule is directed to be placed in the apparatus, for each of the six tablets or capsules tested the amount of active ingredient in solution is not less than 70% of the prescribed or stated amount, unless otherwise specified in the monograph, except that if one fails this requirement a further six may be tested individually and all must comply. Where two or more tablets or capsules are directed to be placed together in the apparatus, a total of six replicate tests are carried out. In each test the amount of active ingredient in solution per tablet or capsule is not less than 70% of the prescribed or stated amount, unless otherwise specified in the monograph. No retesting is permitted.

Where capsule shells interfere with the analysis, remove the contents of no fewer than six capsules as completely as possible and dissolve the empty capsule shells in the specified volume of dissolution medium. Carry out the test as directed in the individual monograph and make any necessary correction. Correction factors should not be greater than 25% of the labelled content.

C. Consistency of Formulated Preparations

1. Uniformity of Weight (Mass)

(Ph. Eur. method 2.9.5)

Weigh individually 20 units taken at random or, for single-dose preparations presented in individual containers, the contents of 20 units, and determine the average mass.

Not more than 2 of the individual masses deviate from the average mass by more than the percentage deviation shown in Table 2.9.5.-1 and none deviates by more than twice that percentage.

For capsules and powders for parenteral administration, proceed as described below.

CAPSULES

Weigh an intact capsule. Open the capsule without losing any part of the shell and remove the contents as completely as possible. For soft shell capsules, wash the shell with a suitable solvent and allow to stand until the odour of the solvent is no longer perceptible. Weigh the shell. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 capsules.

Table 2.9.5.-1

Pharmaceutical Form	Average Mass	Percentage deviation
Tablets (uncoated and film-coated)	80 mg or less	10
	More than 80 mg and less than 250 mg	7.5
	250 mg or more	5
Capsules, granules (uncoated, single-dose) and powders (single-dose)	Less than 300 mg	10
	300 mg or more	7.5
Powders for parenteral administration* (single-dose)	More than 40 mg	10
Suppositories and pessaries	All masses	5
Powders for eye-drops and powders for eye lotions (single-dose)	Less than 300 mg	10
	300 mg or more	7.5

* When the average mass is equal to or below 40 mg, the preparation is not submitted to the test for uniformity of mass but to the test for uniformity of content of single-dose preparations (2.9.6).

POWDERS FOR PARENTERAL ADMINISTRATION

Remove any paper labels from a container and wash and dry the outside. Open the container and without delay weigh the container and its contents. Empty the container as completely as possible by gentle tapping, rinse it if necessary with *water R* and then with *alcohol R* and dry at 100-105 °C for 1 h, or, if the nature of the container precludes heating at this temperature, dry at a lower temperature to constant mass. Allow to cool in a desiccator and weigh. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 containers.

2. Uniformity of Weight (Mass) of Delivered Doses from Multidose Containers

(Ph. Eur. method 2.9.27)

The following test is intended for oral dosage forms such as granules, powders for oral use and liquids for oral use, which are supplied in multidose containers provided at manufacture with a measuring device.

Weigh individually 20 doses taken at random from one or more containers with the measuring device provided and determine the individual and average masses. Not more than 2 of the individual masses deviate from the average mass by more than 10 per cent and none deviates by more than 20 per cent.

3. Uniformity of Content

(Ph. Eur. method 2.9.6)

The test for uniformity of content of single-dose preparations is based on the assay of the individual contents of active substance(s) of a number of single-dose units to determine

whether the individual contents are within limits set with reference to the average content of the sample.

The test is not required for multivitamin and trace-element preparations and in other justified and authorised circumstances.

Method Using a suitable analytical method, determine the individual contents of active substance(s) of 10 dosage units taken at random.

Apply the criteria of test A, test B or test C as specified in the monograph for the dosage form in question.

TEST A

The preparation complies with the test if each individual content is between 85 per cent and 115 per cent of the average content. The preparation fails to comply with the test if more than one individual content is outside these limits or if one individual content is outside the limits of 75 per cent to 125 per cent of the average content.

If one individual content is outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than one of the individual contents of the 30 units is outside 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

TEST B

The preparation complies with the test if not more than one individual content is outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content. The preparation fails to comply with the test if more than 3 individual contents are outside the limits of 85 per cent to 115 per cent of the average content or if one or more individual contents are outside the limits of 75 per cent to 125 per cent of the average content.

If 2 or 3 individual contents are outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than 3 individual contents of the 30 units are outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

TEST C

The preparation complies with the test if the average content of the 10 dosage units is between 90 per cent and 110 per cent of the content stated on the label and if the individual content of each dosage unit is between 75 per cent and 125 per cent of the average content.

4. Uniformity of Dosage Units[1]

(Ph. Eur. method 2.9.40)

To ensure the consistency of dosage units, each unit in a batch should have an active substance content within a narrow range around the label claim. Dosage units are defined as dosage forms containing a single dose or a part of a dose of an active substance in each dosage unit. ◊Unless otherwise stated,◊ the uniformity of dosage units specification is not intended to apply to solutions, suspensions, emulsions or gels in single-dose containers intended for local action following cutaneous administration. ◊The test for content uniformity is not required for multivitamin, single-vitamin and trace-element preparations.◊

The term 'uniformity of dosage unit' is defined as the degree of uniformity in the amount of the active substance among dosage units. Therefore, the requirements of this chapter apply to each active substance being comprised in dosage units containing 1 or more active substances, unless otherwise specified elsewere in this Pharmacopoeia.

The uniformity of dosage units can be demonstrated by either of 2 methods: content uniformity or mass variation (see Table 2.9.40.-1).

The test for content uniformity of preparations presented in dosage units is based on the assay of the individual contents of active substance(s) of a number of dosage units to determine whether the individual contents are within the limits set. The content uniformity method may be applied in all cases.

The test for mass variation is applicable for the following dosage forms:

(1) solutions enclosed in single-dose containers and in soft capsules;

(2) solids (including powders, granules and sterile solids) that are packaged in single-dose containers and contain no added active or inactive substances;

(3) solids (including sterile solids) that are packaged in single-dose containers, with or without added active or inactive substances, that have been prepared from true solutions and freeze-dried in the final containers and are labelled to indicate this method of preparation;

(4) hard capsules, uncoated tablets, or film-coated tablets, containing 25 mg or more of an active substance comprising 25 per cent or more, by mass, of the dosage unit or, in the case of hard capsules, the capsule contents, except that uniformity of other active substances present in lesser proportions is demonstrated by meeting content uniformity requirements.

The test for content uniformity is required for all dosage forms not meeting the above conditions for the mass variation test. ♦Alternatively, products that do not meet the 25 mg/25 per cent threshold limit may be tested for uniformity of dosage units by mass variation instead of the content uniformity test on the following condition: the concentration Relative Standard Deviation (RSD) of the active substance in the final dosage units is not more than 2 per cent, based on process validation data and development data, and if there has been regulatory approval of such a change. The concentration RSD is the RSD of the concentration per dosage unit (*m/m* or *m/V*), where concentration per dosage unit equals the assay result per dosage unit divided by the individual dosage unit mass. See the RSD formula in Table 2.9.40.-2.♦

CONTENT UNIFORMITY

Select not fewer than 30 units, and proceed as follows for the dosage form designated. Where different procedures are used for assay of the preparation and for the content uniformity test, it may be necessary to establish a correction factor to be applied to the results of the latter.

Solid dosage forms

Assay 10 units individually using an appropriate analytical method. Calculate the acceptance value (see Table 2.9.40.-2).

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

Table 2.9.40.-1. – *Application of Content Uniformity (CU) and Mass Variation (MV) test for dosage forms*

Dosage forms	Type	Sub-Type	Dose and ratio of active substance	
			≥ 25 mg and ≥ 25 per cent	< 25 mg or < 25 per cent
Tablets	uncoated		MV	CU
	coated	film-coated	MV	CU
		others	CU	CU
Capsules	hard		MV	CU
	soft	suspensions, emulsions, gels	CU	CU
		solutions	MV	MV
Solids in single-dose containers	single component		MV	MV
	multiple components	solution freeze-dried in final container	MV	MV
		others	CU	CU
Solutions enclosed in single-dose containers			MV	MV
Others: dosage forms not addressed by the other categories in this table including but not limited to suppositories, transdermal patches and semi-solid preparations applied cutaneously and intended for systemic distribution of the active substance			CU	CU

Liquid or semi-solid dosage forms
Assay 10 units individually using an appropriate analytical method. Carry out the assay on the amount of well-mixed material that is removed from an individual container in conditions of normal use. Express the results as delivered dose. Calculate the acceptance value (see Table 2.9.40.-2).

Calculation of Acceptance Value
Calculate the Acceptance Value (*AV*) using the formula:

$$|M - \overline{X}| + ks$$

for which the terms are as defined in Table 2.9.40.-2.

MASS VARIATION
Carry out an assay for the active substance(s) on a representative sample of the batch using an appropriate analytical method. This value is result *A*, expressed as percentage of label claim (see Calculation of Acceptance Value). Assume that the concentration (mass of active substance per mass of dosage unit) is uniform. Select not fewer than 30 dosage units, and proceed as follows for the dosage form designated.

Uncoated or film-coated tablets
Accurately weigh 10 tablets individually. Calculate the active substance content, expressed as percentage of label claim, of each tablet from the mass of the individual tablets and the result of the assay. Calculate the acceptance value.

Hard capsules
Accurately weigh 10 capsules individually, taking care to preserve the identity of each capsule. Remove the contents of each capsule by suitable means. Accurately weigh the emptied shells individually, and calculate for each capsule the net mass of its contents by subtracting the mass of the shell from the respective gross mass. Calculate the active substance content in each capsule from the mass of product removed from the individual capsules and the result of the assay. Calculate the acceptance value.

Soft capsules
Accurately weigh 10 intact capsules individually to obtain their gross masses, taking care to preserve the identity of each capsule. Then cut open the capsules by means of a suitable clean, dry cutting instrument such as scissors or a sharp open blade, and remove the contents by washing with a suitable solvent. Allow the occluded solvent to evaporate from the shells at room temperature over a period of about 30 min, taking precautions to avoid uptake or loss of moisture. Weigh the individual shells, and calculate the net contents. Calculate the active substance content in each capsule from the mass of product removed from the individual capsules and the result of the assay. Calculate the acceptance value.

Solid dosage forms other than tablets and capsules
Proceed as directed for hard capsules, treating each unit as described therein. Calculate the acceptance value.

Liquid ◊or semi-solid◊ dosage forms
Accurately weigh the amount of liquid or semi-solid that is removed from each of 10 individual containers in conditions of normal use. If necessary, compute the equivalent volume after determining the density. Calculate the active substance content in each container from the mass of product removed from the individual containers and the result of the assay. Calculate the acceptance value.

Calculation of Acceptance Value
Calculate the acceptance value (*AV*) as shown in content uniformity, except that the individual contents of the units

Table 2.9.40.-2.

Variable	Definition	Conditions	Value
$\overline{X}$	Mean of individual contents (x_1, x_2,..., x_n), expressed as a percentage of the label claim		
$x_1, x_2,..., x_n$	Individual contents of the dosage units tested, expressed as a percentage of the label claim		
n	Sample size (number of dosage units in a sample)		
k	Acceptability constant	If n = 10, then	2.4
		If n = 30, then	2.0
s	Sample standard deviation		$\left[\frac{\sum_{i=1}^{n}(x_i-\overline{X})^2}{n-1}\right]^{1/2}$
RSD	Relative standard deviation		$\frac{100s}{\overline{X}}$
M (case 1) To be applied when $T \leq$ 101.5	Reference value	If 98.5 per cent $\leq \overline{X} \leq$ 101.5 per cent, then	$M = \overline{X}$ ($AV = ks$)
		If $\overline{X}$ < 98.5 per cent, then	M = 98.5 per cent (AV = 98.5 $-\overline{X} + ks$)
		If $\overline{X}$ > 101.5 per cent, then	M = 101.5 per cent ($AV = \overline{X} - 101.5 + ks$)
M (case 2) To be applied when $T >$ 101.5	Reference value	If 98.5 per cent $\leq \overline{X} \leq T$, then	$M = \overline{X}$ ($AV = ks$)
		If $\overline{X}$ < 98.5 per cent, then	M = 98.5 per cent (AV = 98.5 $-\overline{X} + ks$)
		If $\overline{X} > T$, then	$M = T$ per cent ($AV = \overline{X} - T + ks$)
Acceptance value (AV)			General formula: $\lvert M - \overline{X} \rvert + ks$ Calculations are specified above for the different cases.
$L1$	Maximum allowed acceptance value		$L1$ = 15.0 unless otherwise specified
$L2$	Maximum allowed range for deviation of each dosage unit tested from the calculated value of M	On the low side, no dosage unit result can be less than 0.75 M while on the high side, no dosage unit result can be greater than 1.25 M (This is based on $L2$ value of 25.0)	$L2$ = 25.0 unless otherwise specified
T	Target content per dosage unit at time of manufacture, expressed as a percentage of the label claim. Unless otherwise stated, T is equal to 100 per cent or T is the manufacturer's approved target content per dosage unit		

are replaced with the individual estimated contents defined below.

$x_1, x_2, \ldots, x_n$ = individual estimated contents of the dosage units tested;

where

$$x_i = w_i \times \frac{A}{\overline{W}}$$

$w_1, w_2, \ldots, w_n$ = individual masses of the dosage units tested;
A = content of active substance (percentage of label claim) obtained using an appropriate analytical method (assay);
$\overline{W}$ = mean of individual masses ($w_1, w_2, \ldots, w_n$).

CRITERIA

Apply the following criteria, unless otherwise specified.

Solid, semi-solid and liquid dosage forms

The requirements for dosage uniformity are met if the acceptance value of the first 10 dosage units is less than or equal to $L1$ per cent. If the acceptance value is greater than $L1$ per cent, test the next 20 dosage units and calculate the acceptance value. The requirements are met if the final acceptance value of the 30 dosage units is less than or equal to $L1$ per cent and no individual content of the dosage unit is less than $(1 - L2 \times 0.01)M$ or more than $(1 + L2 \times 0.01)M$ in calculation of acceptance value under content uniformity or under mass variation. Unless otherwise specified, $L1$ is 15.0 and $L2$ is 25.0.

5. Extractable Volume of Parenteral Preparations[2]

(Test for Extractable Volume of Parenteral Preparations, Ph. Eur. method 2.9.17)

Suspensions and emulsions are shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 20-25 °C before measuring the volume.

SINGLE-DOSE CONTAINERS

Select 1 container if the nominal volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. Take up individually the total contents of each container selected into a dry syringe of a capacity not exceeding 3 times the volume to be measured, and fitted with a 21-gauge needle not less than 2.5 cm in length. Expel any air bubbles from the syringe and needle, then discharge the contents of the syringe without emptying the needle into a standardised dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40 per cent of its graduated volume. Alternatively, the volume of the contents in millilitres may be calculated as the mass in grams divided by the density.

For containers with a nominal volume of 2 mL or less, the contents of a sufficient number of containers may be pooled to obtain the volume required for the measurement provided that a separate, dry syringe assembly is used for each container. The contents of containers holding 10 mL or more may be determined by opening them and emptying the contents directly into the graduated cylinder or tared beaker.

The volume is not less than the nominal volume in case of containers examined individually, or, in case of containers with a nominal volume of 2 mL or less, is not less than the sum of the nominal volumes of the containers taken collectively.

MULTIDOSE CONTAINERS

For injections in multidose containers labelled to yield a specific number of doses of a stated volume, select one container and proceed as directed for single-dose containers using the same number of separate syringe assemblies as the number of doses specified.

The volume is such that each syringe delivers not less than the stated dose.

CARTRIDGES AND PREFILLED SYRINGES

Select 1 container if the nominal volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. If necessary, fit the containers with the accessories required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume in millilitres calculated as the mass in grams divided by the density.

The volume measured for each of the containers is not less than the nominal volume.

PARENTERAL INFUSIONS

Select one container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40 per cent of the nominal volume of the cylinder. Measure the volume transferred.

The volume is not less than the nominal volume.

7. Preparations for Inhalation: Aerodynamic Assessment of Fine Particles

(Ph. Eur. method 2.9.18)

This test is used to determine the fine particle characteristics of the aerosol clouds generated by preparations for inhalation.

Unless otherwise justified and authorised, one of the following apparatus and test procedures is used.

Stage mensuration Is performed periodically together with confirmation of other dimensions critical to the effective operation of the impactor.

Re-entrainment (for apparatus D and E) To ensure efficient particle capture, coat each plate with glycerol, silicone oil or similar high viscosity liquid, typically deposited from a volatile solvent. Plate coating must be part of method validation and may be omitted where justified and authorised.

Mass balance The total mass of the active substance is not less than 75 per cent and not more than 125 per cent of the average delivered dose determined during testing for uniformity of delivered dose. This is not a test of the inhaler but it serves to ensure that the results are valid.

APPARATUS A - GLASS IMPINGER

The apparatus is shown in Figure 2.9.18.-1 (see also Table 2.9.18.-1).

Procedure for nebulisers

Introduce 7 mL and 30 mL of a suitable solvent into the upper and lower impingement chambers, respectively.

[2] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the jet spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a suitable pump fitted with a filter (of suitable pore size) to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 L/min.

Introduce the liquid preparation for inhalation into the reservoir of the nebuliser. Fit the mouthpiece and connect it by means of an adapter to the device.

Switch on the pump of the apparatus and after 10 s switch on the nebuliser.

After 60 s, unless otherwise justified, switch off the nebuliser, wait for about 5 s and then switch off the pump of the apparatus. Dismantle the apparatus and wash the inner surface of the upper impingement chamber collecting the washings in a volumetric flask. Wash the inner surface of the lower impingement chamber collecting the washings in a second volumetric flask. Finally, wash the filter preceding the pump and its connections to the lower impingement chamber and combine the washings with those obtained from the lower impingement chamber. Determine the amount of active substance collected in each of the 2 flasks. Express the results for each of the 2 parts of the apparatus as a percentage of the total amount of active substance.

Procedure for pressurised inhalers

Place the actuator adapter in position at the end of the throat so that the mouthpiece end of the actuator, when inserted to a depth of about 10 mm, lines up along the horizontal axis of the throat and the open end of the actuator, which accepts the pressurised container, is uppermost and in the same vertical plane as the rest of the apparatus.

Introduce 7 mL and 30 mL of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the lower jet-spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a suitable pump to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 L/min.

Prime the metering valve by shaking for 5 s and discharging once to waste; after not less than 5 s, shake and discharge again to waste. Repeat a further 3 times.

Shake for about 5 s, switch on the pump to the apparatus and locate the mouthpiece end of the actuator in the adapter, discharge once immediately. Remove the assembled inhaler from the adapter, shake for not less than 5 s, relocate the mouthpiece end of the actuator in the adapter and discharge again. Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. After the final discharge wait for not less than 5 s and then switch off the pump. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent, collecting the washings in the lower impingement chamber. Determine the content of active substance in this solution. Calculate the amount of active substance collected in the lower impingement chamber per discharge and express the results as a percentage of the dose stated on the label.

Procedure for powder inhalers

Introduce 7 mL and 30 mL of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the jet-spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Without the inhaler in place, connect a suitable pump to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 L/min.

Prepare the inhaler for use and locate the mouthpiece in the apparatus by means of a suitable adapter. Switch on the pump for 5 s. Switch off the pump and remove the inhaler. Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent, collecting the washings in the lower impingement chamber. Determine the content of active substance in this solution. Calculate the amount of active substance collected in the lower impingement chamber per discharge and express the results as a percentage of the dose stated on the label.

FINE PARTICLE DOSE AND PARTICLE SIZE DISTRIBUTION

APPARATUS C - MULTI-STAGE LIQUID IMPINGER

The multi-stage liquid impinger consists of impaction stages 1 (pre-separator), 2, 3 and 4 and an integral filter stage (stage 5), see Figures 2.9.18.-4/6. An impaction stage comprises an upper horizontal metal partition wall (B)

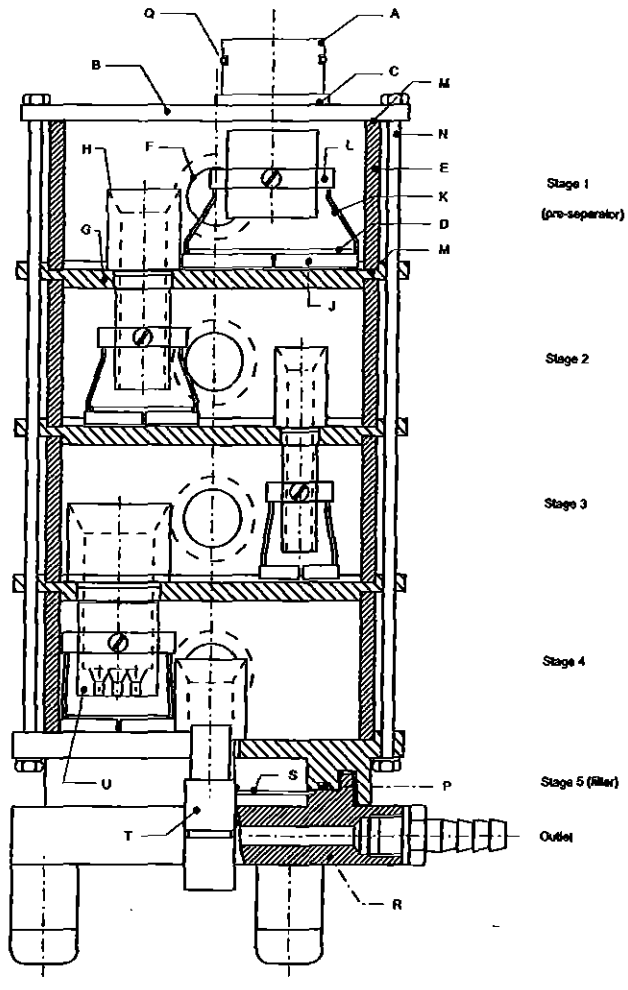

Figure 2.9.18.-4. – *Apparatus C: multi-stage liquid impinger*

through which a metal inlet jet tube (A) with its impaction plate (D) is protruding. A glass cylinder (E) with sampling port (F) forms the vertical wall of the stage, and a lower horizontal metal partition wall (G) through which the tube (H) connects to the next lower stage. The tube into stage 4 (U) ends in a multi-jet arrangement. The impaction plate (D) is secured in a metal frame (J) which is fastened by 2 wires (K) to a sleeve (L) secured on the jet tube.
The horizontal face of the collection plate is perpendicular to the axis of the jet tube and centrally aligned. The upper surface of the impaction plate is slightly raised above the edge of the metal frame. A recess around the perimeter of the horizontal partition wall guides the position of the glass cylinder. The glass cylinders are sealed against the horizontal partition walls with gaskets (M) and clamped together by 6 bolts (N). The sampling ports are sealed by stoppers.
The bottom-side of the lower partition wall of stage 4 has a concentrical protrusion fitted with a rubber O-ring (P) which seals against the edge of a filter placed in the filter holder. The filter holder (R) is constructed as a basin with a concentrical recess in which a perforated filter support (S) is flush-fitted. The filter holder is dimensioned for 76 mm diameter filters. The assembly of impaction stages is clamped onto the filter holder by 2 snap-locks (T). Connect an induction port (see Figure 2.9.18.-7) onto the stage 1 inlet jet tube of the impinger. A rubber O-ring on the jet tube provides an airtight connection to the induction port.
A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port. The front

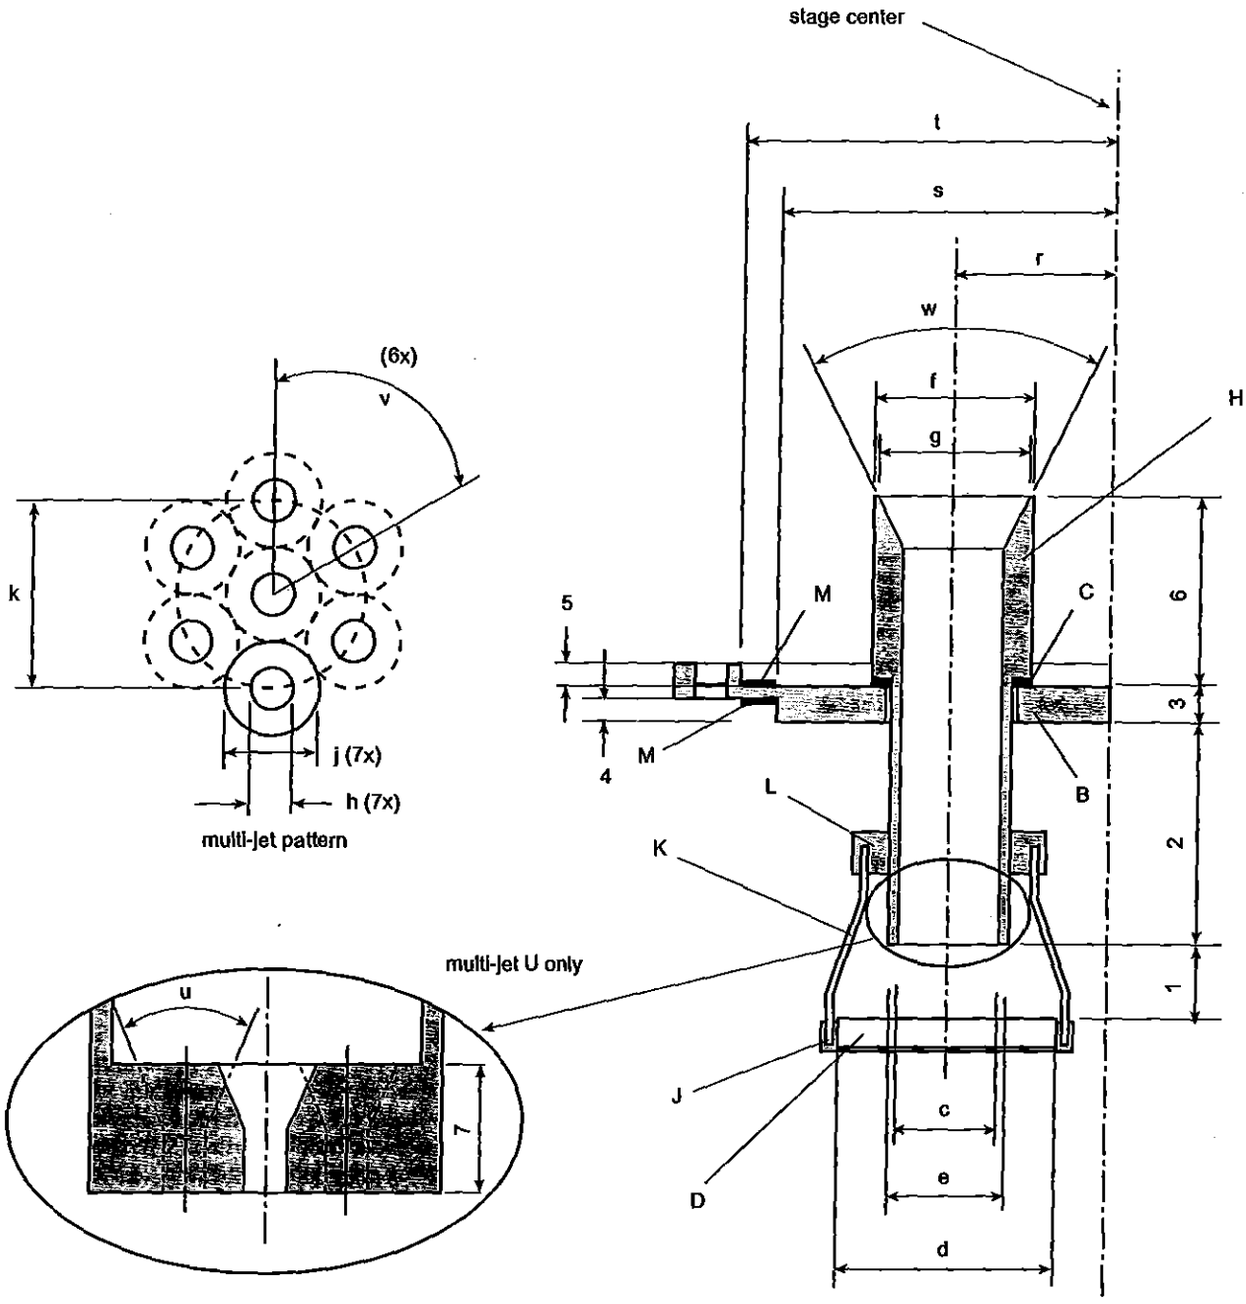

Figure 2.9.18.-5. – *Apparatus C: details of jet tube and impaction plate. Inserts show end of multi-jet tube U leading to stage 4. (Numbers and lowercase letters refer to Table 2.9.18.-3 and uppercase letters refer to Figure 2.9.18.-4).*

face of the inhaler mouthpiece must be flush with the front face of the induction port.

Procedure for pressurised inhalers

Dispense 20 mL of a solvent, capable of dissolving the active substance into each of stages 1 to 4 and replace the stoppers. Tilt the apparatus to wet the stoppers, thereby neutralising electrostatic charge. Place a suitable filter capable of quantitatively collecting the active substance in stage 5 and assemble the apparatus. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler is positioned in the same orientation as intended for use. Connect a suitable vacuum pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 30 L/min (± 5 per cent). Switch off the pump.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge 1 delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge the inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

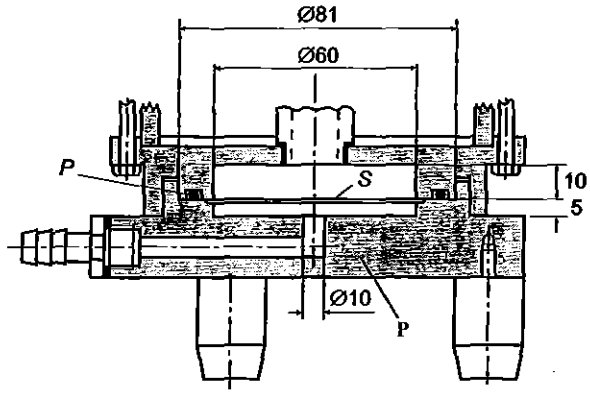

Figure 2.9.18.-6. – *Apparatus C: details of the filter stage (stage 5). Numbers refer to dimensions (Ø = diameter). Uppercase letters refer to Table 2.9.18.-2. Dimensions in millimetres unless otherwise stated*

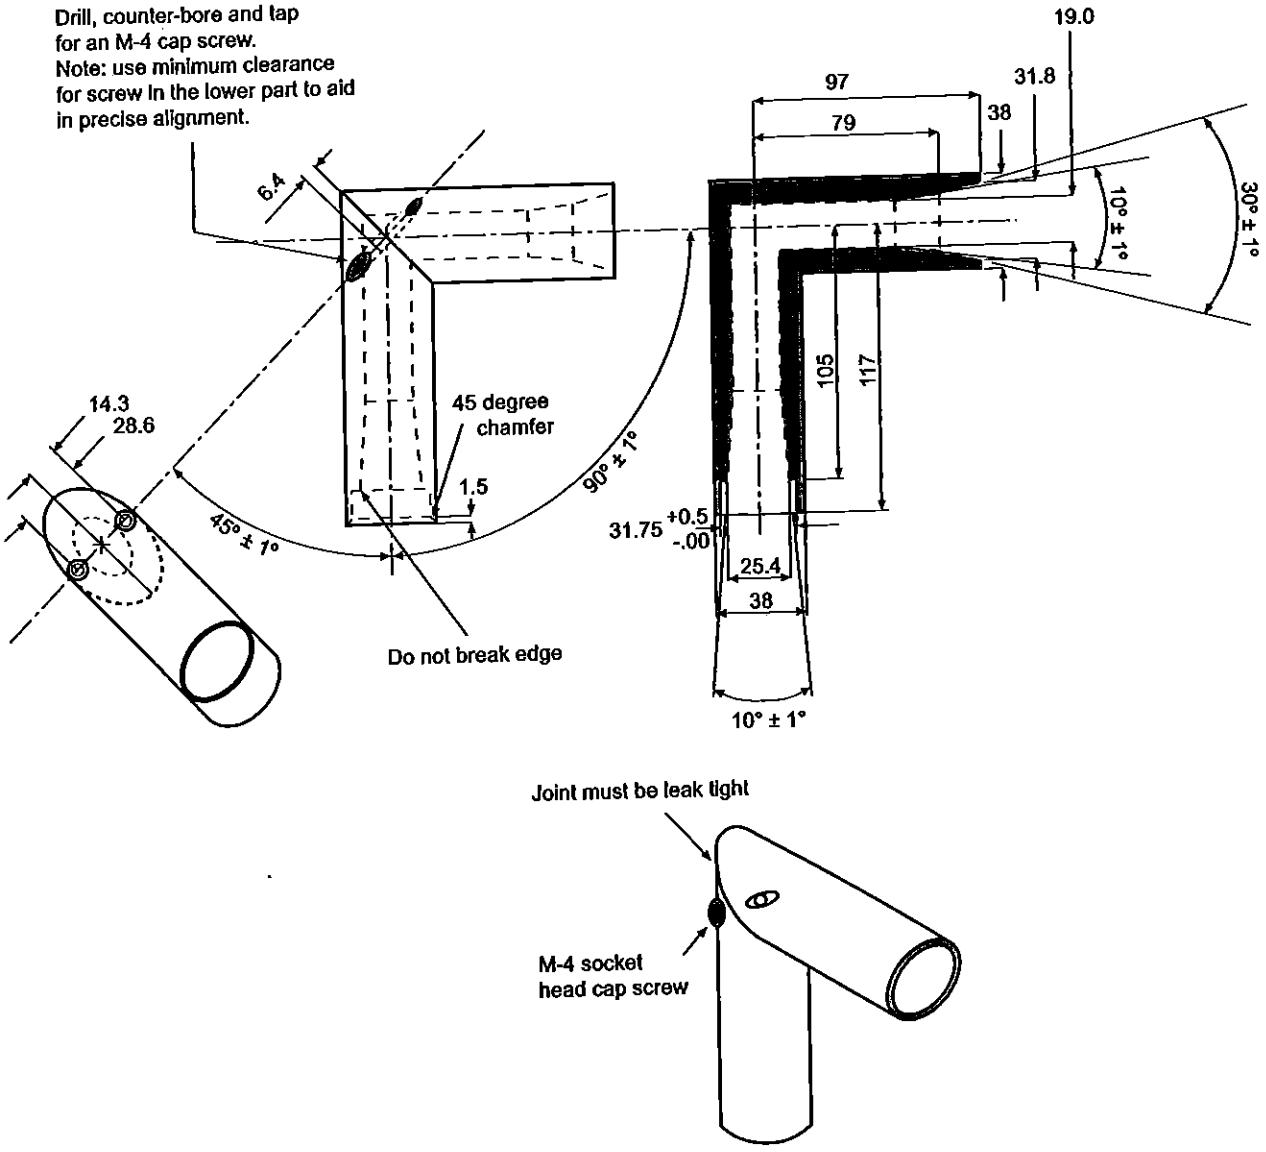
Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active substance from the inner walls and the collection plate of each of the 4 upper stages of the apparatus into the solution in the respective



Isometric view of induction port

1. Material may be aluminium, stainless steel or other suitable material.
2. Machine from 38 mm bar stock.
3. Bore 19 mm hole through bar.
4. Cut tube to exact 45° as shown.
5. The inner bores and tapers should be smooth – surface roughness Ra approx. 0.4 µm.
6. Mill joining ends of stock to provide a liquid tight leak-free seal.
7. Set up a holding fixture for aligning the inner 19 mm bore and for drilling and tapping M4 × 0.7 threads. There must be virtually no mismatch of the inner bores in the miter joint.

Figure 2.9.18.-7. – *Induction port*
Dimensions in millimetres unless otherwise stated

stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

Procedure for powder inhalers

Place a suitable low resistance filter capable of quantitatively collecting the active substance in stage 5 and assemble the apparatus. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4. Unless otherwise defined, conduct the test at the flow rate, Q_{out}, used in the test for uniformity of delivered dose, drawing 4 L of air from the mouthpiece of the inhaler and through the apparatus.

Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter (Q_{out}) using the ideal gas law. For a meter calibrated for the entering

volumetric flow (Q_{in}), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

P_0 = atmospheric pressure,
ΔP = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, Q_{out} (± 5 per cent). Switch off the pump. Ensure that critical flow occurs in the flow control valve by the following procedure.

With the inhaler in place and the test flow rate established, measure the absolute pressure on both sides of the control valve (pressure reading points P2 and P3 in Figure 2.9.18.-8). A ratio P3/P2 of less than or equal to 0.5 indicates critical flow. Switch to a more powerful pump and re-measure the test flow rate if critical flow is not indicated.

Dispense 20 mL of a solvent, capable of dissolving the active substance into each of the 4 upper stages of the apparatus and replace the stoppers. Tilt the apparatus to wet the stoppers, thereby neutralising electrostatic charge. Place a suitable mouthpiece adapter in position at the end of the induction port.

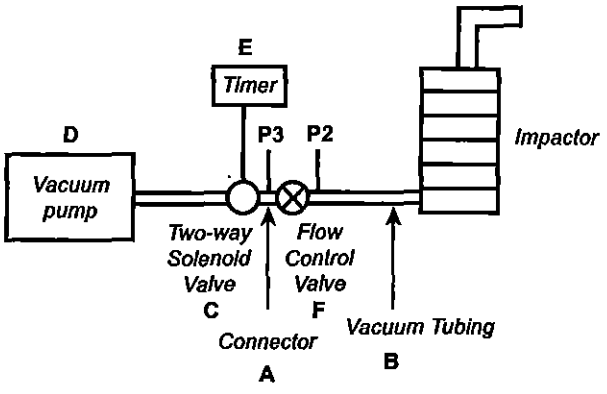


Figure 2.9.18.-8. – *Experimental set-up for testing powder inhalers*

Prepare the powder inhaler for use according to patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active substance from the inner walls and the collection plate of each of the 4 upper stages of the apparatus into the solution in the respective stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages.

Using a suitable method of analysis, determine the amount of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

Table 2.9.18.-4. – *Component specification for Figure 2.9.18.-8*

Code	Item	Description
A	Connector	ID ≥ 8 mm, e.g., short metal coupling, with low-diameter branch to P3.
B	Vacuum tubing	A length of suitable tubing having an ID ≥ 8 mm and an internal volume of 25 ± 5 mL.
C	2-way solenoid valve	A 2-way, 2-port solenoid valve having a minimum airflow resistance orifice with ID ≥ 8 mm and an opening time ≤ 100 ms. (e.g. type 256-A08, Bürkert GmbH, D-74653 Ingelfingen), or equivalent.
D	Vacuum pump	Pump must be capable of drawing the required flow rate through the assembled apparatus with the powder inhaler in the mouthpiece adapter (e.g. product type 1023, 1423 or 2565, Gast Manufacturing Inc., Benton Harbor, MI 49022), or equivalent. Connect the pump to the 2-way solenoid valve using short and/or wide (ID ≥ 10 mm) vacuum tubing and connectors to minimise pump capacity requirements.
E	Timer	Timer capable to drive the 2-way solenoid valve for the required duration (e.g. type G814, RS Components International, Corby, NN17 9RS, UK), or equivalent.
P2 P3	Pressure measurements	Determine under steady-state flow condition with an absolute pressure transducer.
F	Flow control valve	Adjustable regulating valve with maximum $C_v \geq 1$, (e.g. type 8FV12LNSS, Parker Hannifin plc., Barnstaple, EX31 1NP, UK), or equivalent.

APPARATUS D - ANDERSEN CASCADE IMPACTOR

The Andersen 1 ACFM non-viable cascade impactor consists of 8 stages together with a final filter. Material of construction may be aluminium, stainless steel or other suitable material. The stages are clamped together and sealed with O-rings. Critical dimensions applied by the manufacturer of apparatus D are provided in Table 2.9.18.-5. In use, some occlusion and wear of holes will occur. In-use mensuration tolerances need to be justified. In the configuration used for pressurised inhalers (Figure 2.9.18.-9) the entry cone of the impactor is connected to an induction port (see Figure 2.9.18.-7). A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port.

In the configuration for powder inhalers, a pre-separator is placed above the top stage to collect large masses of non-respirable powder. It is connected to the induction port as shown in Figure 2.9.18.-10. To accommodate high flow rates through the impactor, the outlet nipple, used to connect the impactor to the vacuum system is enlarged to have an internal diameter of greater than or equal to 8 mm.

Procedure for pressurised inhalers

Assemble the Andersen impactor with a suitable filter in place. Ensure that the system is airtight. In that respect, follow the manufacturer's instructions. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler unit is positioned in the same orientation as the intended use. Connect a suitable pump to the outlet of

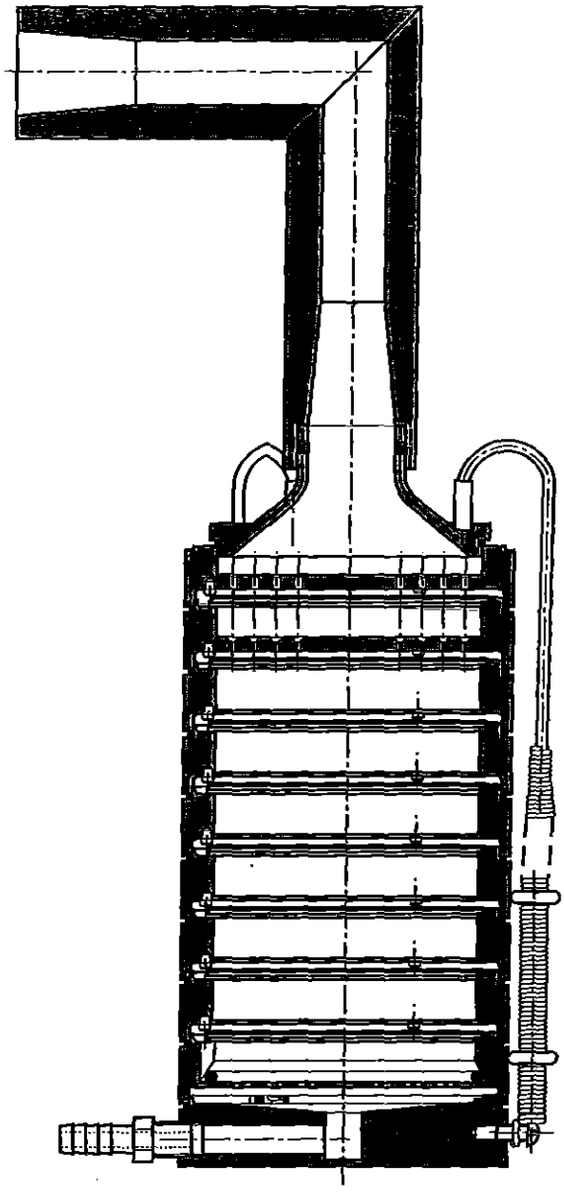

Figure 2.9.18.-9. – *Apparatus D: Andersen cascade impactor used for pressurised inhalers*

Table 2.9.18.-5. – *Critical dimensions for apparatus D*

Description	Number	Dimension (mm)
Stage 0 nozzle diameter	96	2.55 ± 0.025
Stage 1 nozzle diameter	96	1.89 ± 0.025
Stage 2 nozzle diameter	400	0.914 ± 0.0127
Stage 3 nozzle diameter	400	0.711 ± 0.0127
Stage 4 nozzle diameter	400	0.533 ± 0.0127
Stage 5 nozzle diameter	400	0.343 ± 0.0127
Stage 6 nozzle diameter	400	0.254 ± 0.0127
Stage 7 nozzle diameter	201	0.254 ± 0.0127

the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 28.3 L/min (± 5 per cent). Switch off the pump.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge one delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge the inverted inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. Extract the active substance from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

Procedure for powder inhalers

The aerodynamic cut-off diameters of the individual stages of this apparatus are currently not well-established at flow rates other than 28.3 L/min. Users must justify and validate the use of the impactor in the chosen conditions, when flow rates different from 28.3 L/min are selected.

Assemble the Andersen impactor with the pre-separator and a suitable filter in place and ensure that the system is airtight. Depending on the product characteristics, the pre-separator may be omitted, where justified and authorised. Stages 6 and 7 may also be omitted at high flow rates, if justified. The pre-separator may be coated in the same way as the plates or may contain 10 mL of a suitable solvent. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4.

Unless otherwise defined, conduct the test at the flow rate, Q_{out}, used in the test for uniformity of delivered dose drawing 4 L of air from the mouthpiece of the inhaler and through the apparatus.

Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter (Q_{out}) using the ideal gas law. For a meter calibrated for the entering volumetric flow (Q_{in}), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

P_0 = atmospheric pressure,
ΔP = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, Q_{out} (± 5 per cent). Ensure that critical flow occurs in the flow control valve by the procedure described for Apparatus C. Switch off the pump.

Prepare the powder inhaler for use according to the patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

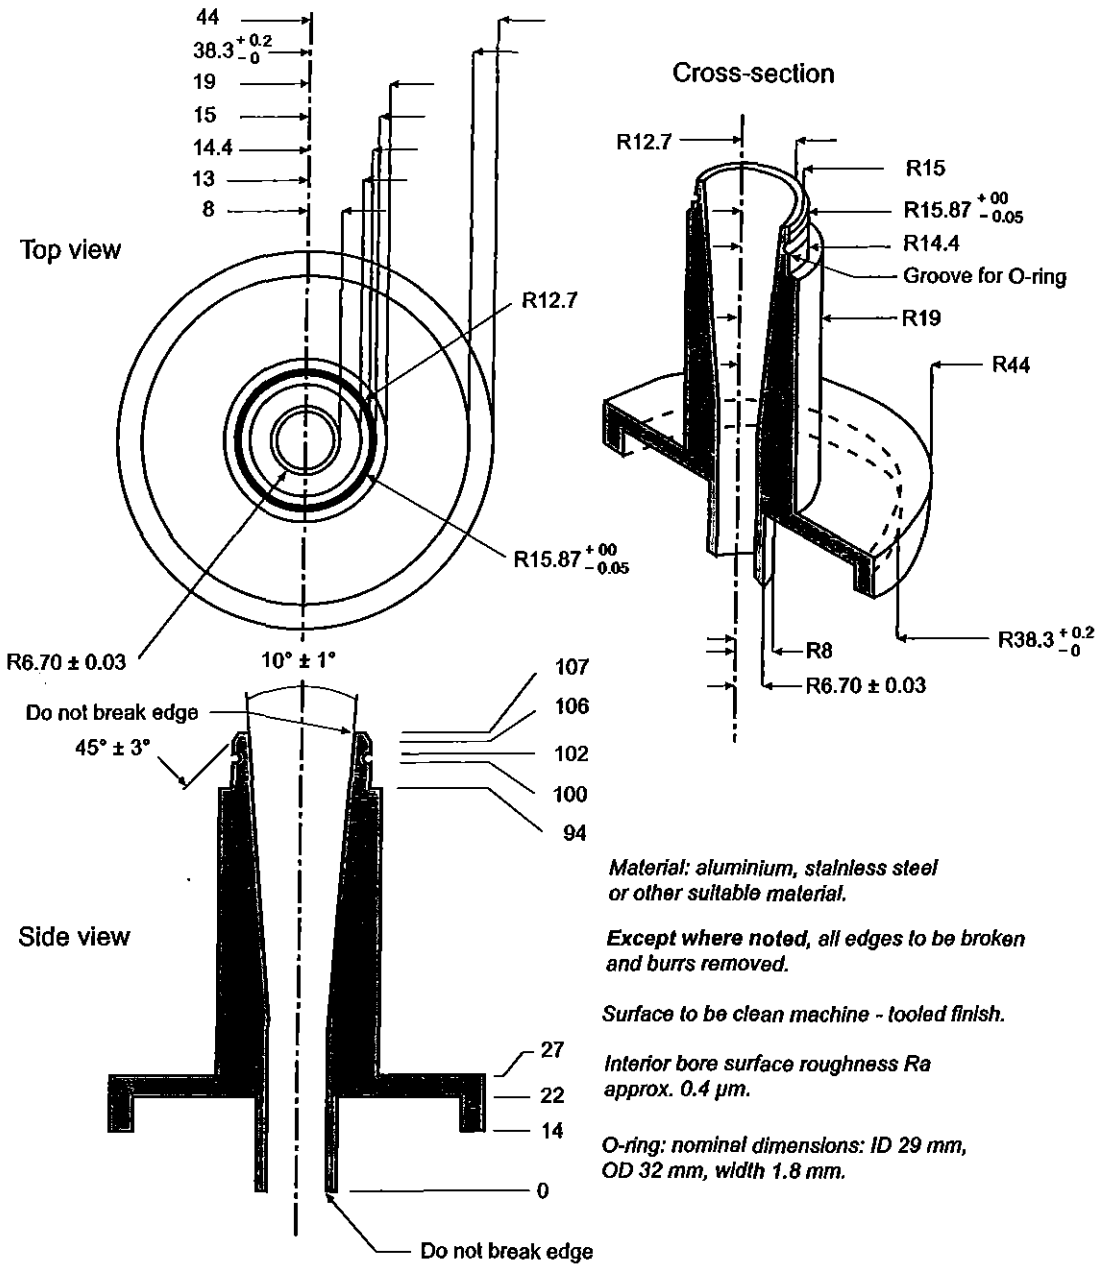

Figure 2.9.18.-10. – *Connection of the induction port to the preseparator of the Andersen cascade impactor Dimensions in millimetres unless otherwise stated*

Dismantle the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the pre-separator, induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. Extract the active substance from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

APPARATUS E

Apparatus E is a cascade impactor with 7 stages and a micro-orifice collector (MOC). Over the flow rate range of 30 L/min to 100 L/min the 50 per cent-efficiency cut-off diameters (D_{50} values) range between 0.24 µm to 11.7 µm, evenly spaced on a logarithmic scale. In this flow range, there are always at least 5 stages with D_{50} values between 0.5 µm and 6.5 µm. The collection efficiency curves for each stage are sharp and minimise overlap between stages.

Material of construction may be aluminium, stainless steel or other suitable material.

The impactor configuration has removable impaction cups with all the cups in one plane (Figures 2.9.18.-11/14). There are 3 main sections to the impactor; the bottom frame that holds the impaction cups, the seal body that holds the jets and the lid that contains the interstage passageways (Figures 2.9.18.-11/12). Multiple nozzles are used at all but the first stage (Figure 2.9.18.-13). The flow passes through the impactor in a saw-tooth pattern.

Critical dimensions are provided in Table 2.9.18.-6.

In routine operation, the seal body and lid are held together as a single assembly. The impaction cups are accessible when this assembly is opened at the end of an inhaler test.

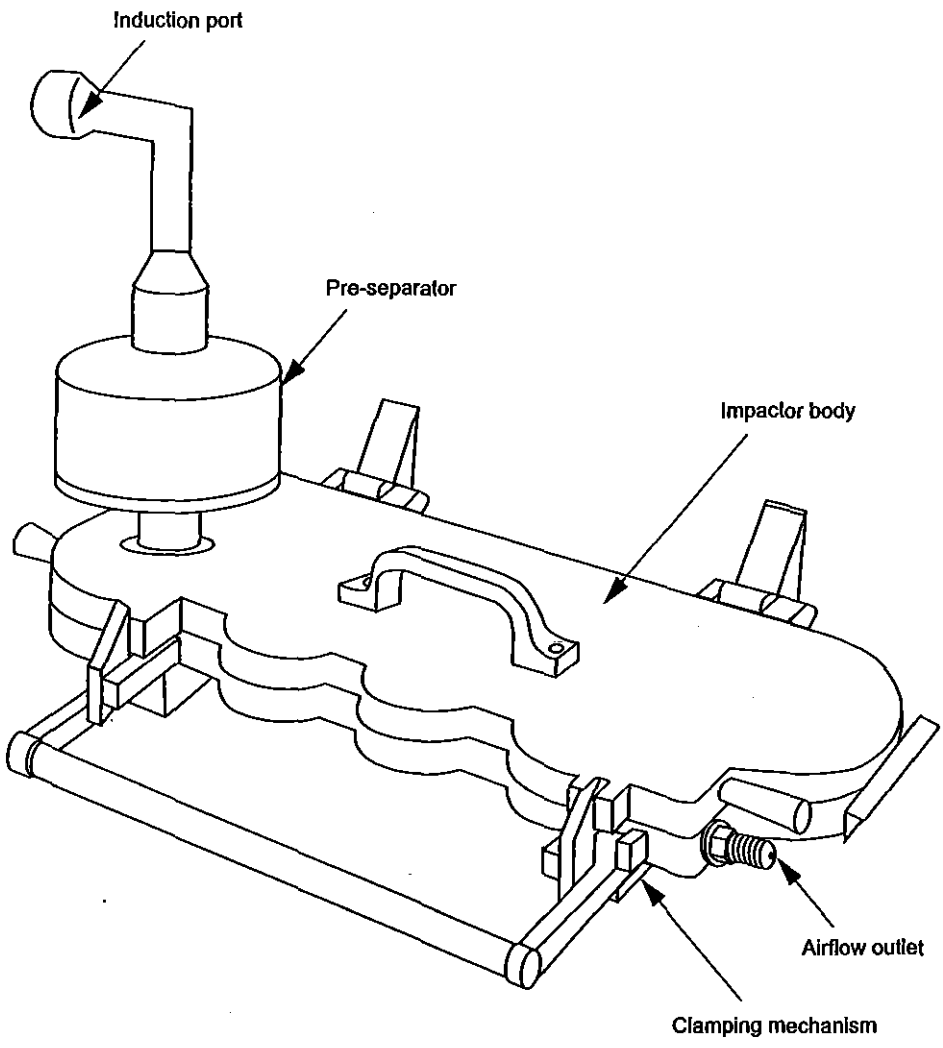

Figure 2.9.18.-11. – *Apparatus E (shown with the pre-separator in place)*

The cups are held in a support tray, so that all cups can be removed from the impactor simultaneously by lifting out the tray.

An induction port with internal dimensions (relevant to the airflow path) defined in Figure 2.9.18.-7 connects to the impactor inlet. A pre-separator can be added when required, typically with powder inhalers, and connects between the induction port and the impactor. A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port.

Apparatus E contains a terminal Micro-Orifice Collector (MOC) that for most formulations will eliminate the need for a final filter as determined by method validation. The MOC is an impactor plate with nominally 4032 holes, each approximately 70 µm in diameter. Most particles not captured on stage 7 of the impactor will be captured on the cup surface below the MOC. For impactors operated at 60 L/min, the MOC is capable of collecting 80 per cent of 0.14 µm particles. For formulations with a significant fraction of particles not captured by the MOC, there is an optional filter holder that can replace the MOC or be placed downstream of the MOC (a glass fibre filter is suitable).

Procedure for pressurised inhalers

Place cups into the apertures in the cup tray. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached and operate the handle to lock the impactor together so that the system is airtight.

Connect an induction port with internal dimensions defined in Figure 2.9.18.-7 to the impactor inlet. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port. When attached to the mouthpiece adapter, the inhaler is positioned in the same orientation as intended for use. Connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 30 L/min (± 5 per cent). Switch off the pump.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge 1 delivery to waste. Switch on the pump to the apparatus. Prepare the inhaler for use according to the patient instructions, locate the mouthpiece end of the actuator in the adapter and discharge the inhaler into the apparatus, depressing the valve for a sufficient time to ensure a complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised, and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

* See Figure 2.9.18.-13
** See Figure 2.9.18.-14

Dismantle the apparatus and recover the active substance as follows: remove the induction port and mouthpiece adapter from the apparatus and recover the deposited active substance into an aliquot of solvent. Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active substance in each cup into an aliquot of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

Procedure for powder inhalers

Assemble the apparatus with the pre-separator (Figure 2.9.18.-15). Depending on the product characteristics, the pre-separator may be omitted, where justified.

Place cups into the apertures in the cup tray. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached and operate the handle to lock the impactor together so that the system is airtight.

When used, the pre-separator should be assembled as follows: assemble the pre-separator insert into the pre-separator base. Fit the pre-separator base to the impactor inlet. Add 15 mL of the solvent used for sample recovery to the central cup of the pre-separator insert. Place the pre-separator body on top of this assembly and close the 2 catches.

Connect an induction port with internal dimensions defined in Figure 2.9.18.-7 to the impactor inlet or pre-separator inlet. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the inhaler, when inserted, lines up along the horizontal axis of the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port. When attached to the mouthpiece adapter, the inhaler is positioned in the same orientation as intended for use. Connect the

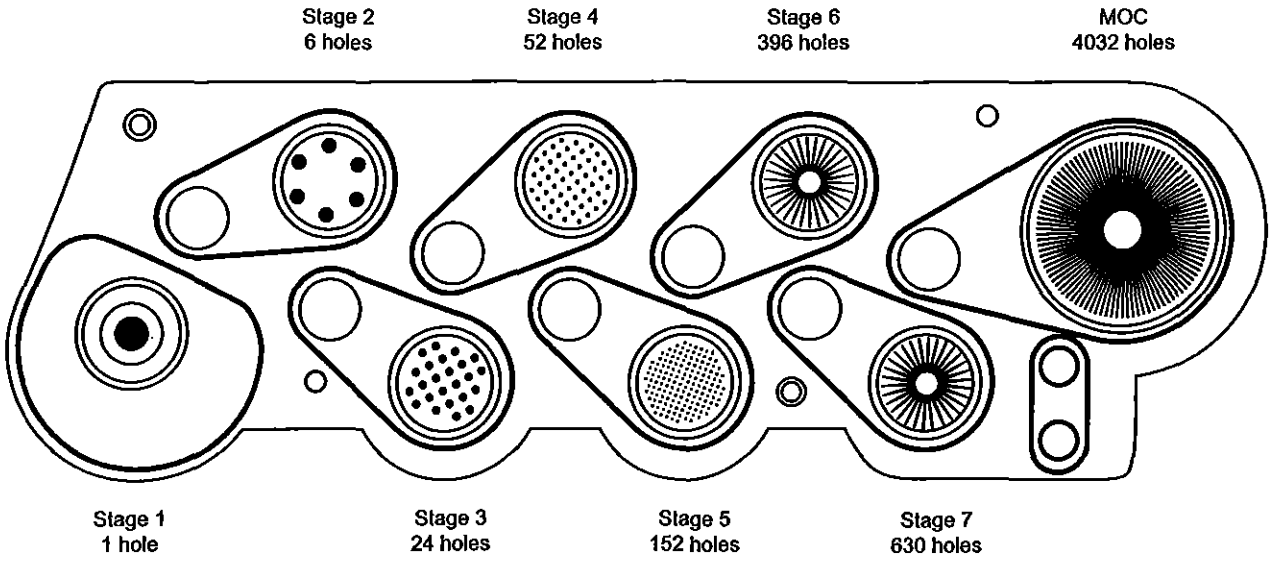

Figure 2.9.18.-13. – *Apparatus E: nozzle configuration*

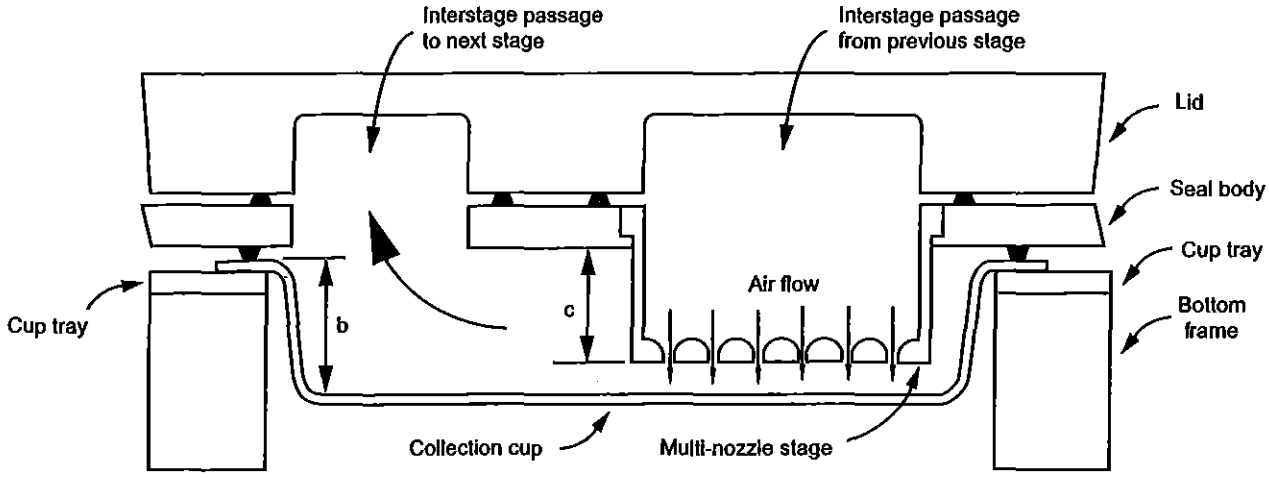

Figure 2.9.18.-14. – *Apparatus E: configuration of interstage passageways*

apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4.

Unless otherwise prescribed, conduct the test at the flow rate, Q_{out}, used in the test for uniformity of delivered dose drawing 4 L of air from the mouthpiece of the inhaler and through the apparatus. Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter (Q_{out}) using the ideal gas law. For a meter calibrated for the entering volumetric flow (Q_{in}), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

P_0 = atmospheric pressure,
ΔP = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, Q_{out} (± 5 per cent). Ensure that critical flow occurs in the flow control valve by the procedure described for Apparatus C. Switch off the pump.

Prepare the powder inhaler for use according to the patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the discharge sequence.

The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the apparatus and recover the active substance as follows: remove the induction port and mouthpiece adapter from the pre-separator, when used, and recover the deposited active substance into an aliquot of solvent. When used, remove the pre-separator from the impactor, being careful to avoid spilling the cup liquid into the impactor. Recover the active substance from the pre-separator.

Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active substance in each cup into an aliquot of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

CALCULATIONS

From the analysis of the solutions, calculate the mass of active substance deposited on each stage per discharge and the mass of active substance per discharge deposited in the

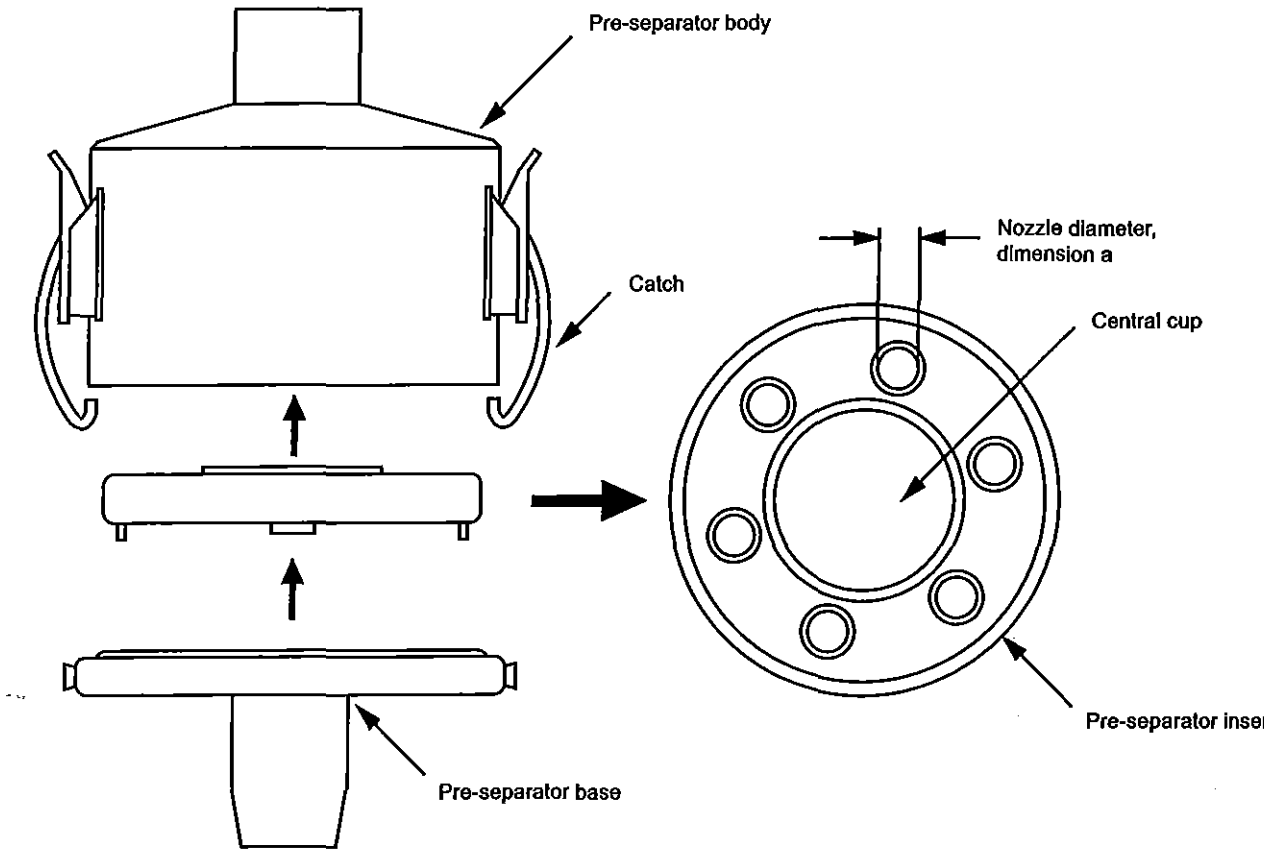

Figure 2.9.18.-15. – *Apparatus E: pre-separator configuration*

induction port, mouthpiece adapter and when used, the pre-separator.

Starting at the final collection site (filter or MOC), derive a table of cumulative mass versus cut-off diameter of the respective stage (see Tables 2.9.18.-7 for Apparatus C, 2.9.18.-8 for Apparatus D, 2.9.18.-9 for Apparatus E). Calculate by interpolation the mass of the active substance less than 5 µm. This is the Fine Particle Dose (FPD).

If necessary, and where appropriate (e.g., where there is a log-normal distribution), plot the cumulative fraction of active substance versus cut-off diameter (see Tables 2.9.18.-7/9) on log probability paper, and use this plot to determine values for the Mass Median Aerodynamic Diameter (MMAD) and Geometric Standard Deviation (GSD) as appropriate. Appropriate computational methods may also be used.

8. Preparations for Nebulisation: Characterisation *(Ph. Eur. method 2.9.44)*

Products used for nebulisation and intended for pulmonary delivery are characterised using the following tests:

— Active substance delivery rate and total active substance delivered;

— Aerodynamic assessment of nebulised aerosols.

These tests standardise the approach given to the assessment of the dose that would be delivered to a patient but are not intended to provide assessment of the nebuliser device itself, which is described in the European standard EN 13544-1:2007+A1:2009, Respiratory therapy equipment - Part 1: Nebulizing systems and their components.

The mass- rather than the number-weighted size distribution is more appropriate to evaluate product performance. Indeed, active substance mass as a function of aerodynamic diameter is more indicative of therapeutic effect within the respiratory tract.

ACTIVE SUBSTANCE DELIVERY RATE AND TOTAL ACTIVE SUBSTANCE DELIVERED

These tests are performed to assess the rate of delivery to the patient and the total active substance delivered to the patient, using standardised conditions of volumetric flow rate. It is essential that breath-enhanced and breath-actuated nebulisers be evaluated by a breathing simulator, as the output of these types of device is highly dependent on inhalation flow rate. The methodology below describes the use of a standard breathing pattern defined for adults. Should a particular product for nebulisation only be indicated for paediatric (i.e. neonate, infant or child) use, then paediatric breathing pattern(s) must be used. Breathing patterns are used, rather than continuous flow rates, to provide a more appropriate measure of the mass of active substance that would be delivered to patients.

Active substance delivery rate and total active substance delivered are appropriate characteristics because they allow the mass delivered to be characterised in a standard way regardless of the nebuliser used. Accordingly, the test methodology described below allows that the mass of active substance delivered in the 1st period (typically 1 min) is measured (consequently giving an assessment of active substance delivery rate) as well as capturing the total mass of active substance delivered.

APPARATUS

Breathing simulator

A commercially available breathing simulator, which is able to generate the breathing profiles specified in Table 2.9.44.-1, is used for the test. The breathing profile indicated for adults is used unless the medicinal product is specifically intended for use in paediatrics, where alternate patterns should be used, as indicated in Table 2.9.44.-1.

Table 2.9.44.-1. – *Breathing simulator specifications*

Item	Specification			
	Adult	Neonate	Infant	Child
Tidal volume	500 mL	25 mL	50 mL	155 mL
Frequency	15 cycles/min	40 cycles/min	30 cycles/min	25 cycles/min
Waveform	sinusoidal	sinusoidal	sinusoidal	sinusoidal
Inhalation/ exhalation ratio	1:1	1:3	1:3	1:2

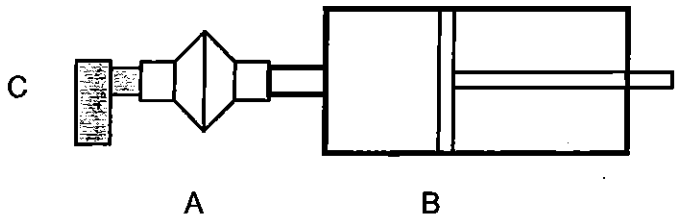
Filter system

A suitably validated low-resistance filter, capable of quantitatively collecting the aerosol and enabling recovery of the active substance with an appropriate solvent, is used for the test. The dead volume of the filter casing does not exceed 10 per cent of the tidal volume used in the breath simulation.

METHOD

Attach the filter (contained in the filter holder) (A) to the breath simulator (B) according to Figure 2.9.44.-1. Fill the nebuliser (C) with the volume of the medicinal product as specified in the patient instructions. Attach the mouthpiece of the nebuliser to the inhalation filter using a mouthpiece adapter if required, ensuring that connections are airtight. Make sure the nebuliser is positioned in the same orientation as intended for use; this may require tilting the breathing simulator and filter holder. Set the breathing simulator to generate the specified breathing pattern.

Start the breathing simulator then, at the beginning of an inhalation cycle, start the nebuliser. Operate the nebuliser for a defined initial time period. The time chosen, usually



A. inhalation filter and filter holder B. breathing simulator C. nebuliser

Figure 2.9.44.-1. – *Experimental set-up for breathing simulator testing*

60 ± 1 s, must allow sufficient active substance deposition on the inhalation filter to allow quantitative analysis. If the quantity of active substance deposited on the inhalation filter in 60 s is insufficient for this analysis, the length of the time interval for aerosol collection can be increased. If the filter is soaked with the preparation, this time can be decreased. At the end of this initial period, stop the nebuliser.

Place a fresh filter and filter holder in position and continue until nebulisation ceases. Interrupt nebulisation and exchange filters if necessary, to avoid filter saturation.

RESULTS

Using a suitable method of analysis, determine the mass of active substance collected on the filters and filter holders during each time interval. Determine the active substance delivery rate by dividing the mass of active substance collected on the first inhalation filter by the time interval used for collection. Determine the total mass of active substance delivered by summing the mass of active substance collected on all inhalation filters and filter holders.

AERODYNAMIC ASSESSMENT OF NEBULISED AEROSOLS

Nebulised products need to be size-characterised at flow rates lower than the range that is normally used for powder inhalers and metered-dose inhalers. A flow rate of 15 L/min is recommended in the European standard because this value represents a good approximation to the mid-inhalation flow rate achievable by a tidally breathing healthy adult (500 mL tidal volume).

Although low-angle laser light scattering instruments (laser diffractometers) can provide rapid size-distribution measurements of nebuliser-generated aerosols, these techniques do not detect the active substance; rather they measure the size distribution of the droplets irrespective of their content. This may not be a problem with homogeneous solutions, but can result in significant error if the product to be nebulised is a suspension, or if droplet evaporation is significant as can be the case with certain nebuliser types. Cascade impactors enable the aerosol to be characterised unambiguously in terms of the mass of active substance as a function of aerodynamic diameter. Laser diffraction may be used if validated against a cascade impaction method.

Apparatus E (see below under Apparatus), a cascade impactor, has been calibrated at 15 L/min specifically to meet the recommendation of the European standard, and is therefore used for this test. Determining mass balance in the same way as for powder inhalers and metered-dose inhalers is not straightforward, in that the dose is being captured as a continuous output, and hence is not included. As part of method development, recovery experiments must be performed to validate the method.

It is also recognised that the control of evaporation of droplets produced by nebulisers may be critical to avoid bias in the droplet size assessment process. Evaporation can be minimised by cooling the impactor to a temperature of about 5 °C, typically achieved by cooling the impactor in a refrigerator for about 90 min. Typically, at least after each day of use, the apparatus must be fully cleaned, including the inter-stage passageways, in view of the greater risk of corrosion caused by the condensation/accumulation of saline-containing droplets on inter-stage metalwork associated with cooling the impactor. It is recommended to dry all surfaces of the apparatus after each test, for example with compressed air. Note: the micro-orifice collector (MOC) should not be dried with compressed air.

APPARATUS

A detailed description of Apparatus E and the induction port is contained in general chapter *2.9.18*, and includes details of critical dimensions and the qualification process for the impactor (stage mensuration).

A back-up filter in addition to the micro-orifice collector (MOC) must be used to ensure quantitative recovery of active substance from the nebulised aerosol at the specified flow rate of 15 L/min. The filter is located below the MOC (internal filter option) or a filter in holder, external to the impactor, is used to capture any fine droplets that pass beyond the last size fractionating stage.

A pre-separator is not used for testing nebuliser-generated aerosols.

METHOD VALIDATION

Impactor stage overloading

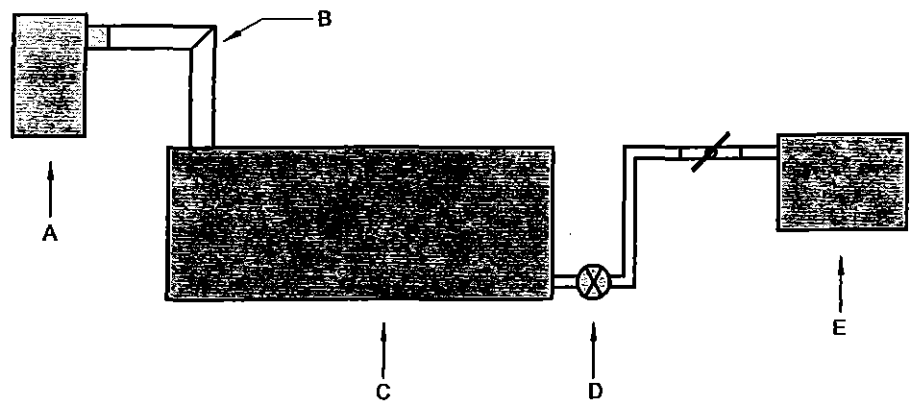
During method development and validation, it is important to confirm that the volume of liquid sampled from the nebuliser does not overload the impactor. Visual inspection of the collection surfaces on stages collecting most of the droplets may reveal streaking if overloading has occurred. This phenomenon is usually also associated with an increase in mass of active substance collected on the final stage and back-up filter. Reducing the sampling period (T_0) is the most effective way to avoid overloading in any given system, balancing overloading with analytical sensitivity.

Re-entrainment

Droplet bounce and re-entrainment are less likely with nebuliser-produced droplets than with solid particles from inhalers and for that reason coating would not normally be required.

METHOD

Pre-cool the assembled impactor and induction port in a refrigerator (set at about 5 °C) for not less than 90 min and start the determination within about 5 min of removal of the impactor from the refrigerator. Other methods that maintain



A. nebuliser B. induction port C. impactor (apparatus B) D. flow control valve E. vacuum source

Figure 2.9.44.-2. – *Apparatus E for measuring the size distribution of preparations for nebulisation*

the impactor at a constant temperature (for example, use of a cooling cabinet) can also be employed when validated.

Set up the nebuliser with a supply of driving gas (usually air or oxygen), or use a compressor, at the pressure and flow rate specified by the manufacturer of the nebuliser. Take precautions to ensure that the gas supply line does not become detached from the nebuliser when under pressure. Fill the nebuliser with the volume of the medicinal product as specified in the patient instructions.

Remove the impactor from the refrigerator. Attach the induction port to the impactor, and connect the outlet of the impactor/external filter to a vacuum source that is capable of drawing air through the system at 15 L/min as specified in Figure 2.9.44.-2. Turn on the flow through the impactor.

Connect a flow meter, calibrated for the volumetric flow leaving the meter, to the induction port. Adjust the flow control valve located between the impactor and the vacuum source to achieve a steady flow through the system at 15 L/min (± 5 per cent). Remove the flow meter.

Make sure the nebuliser is positioned in the same orientation as intended for use then attach the mouthpiece of the nebuliser to the induction port, using a mouthpiece adapter if required, ensuring that connections are airtight. Switch on the flow/compressor for the nebuliser. Sample for a predetermined time (T_0). Once determined, this time (T_0) must be defined and used in the analytical method for a particular medicinal product to ensure that mass fraction data can be compared. At the end of the sampling period, switch off the driving gas flow/compressor to the nebuliser, remove the nebuliser from the induction port and switch off the flow from the vacuum source to the impactor.

Dismantle the impactor and, using a suitable method of analysis, determine the mass of active substance collected in the induction port, on each stage and on the back-up filter/external filter as described for Apparatus E in general chapter *2.9.18.* Add the mass of active substance collected in the MOC to that deposited on the back-up filter/external filter and treat as a single sample for the purpose of subsequent calculations.

Calculate the mass fraction ($F_{m,comp}$) of the active substance deposited on each component of the impactor, commencing with the induction port and proceeding in order through the impactor, using the following expression:

$$F_{m,comp} = \frac{m_{comp}}{M}$$

m_{comp} = mass associated with the component under evaluation;
M = total mass collected by the system.

Present $F_{m,comp}$ in order of location within the measurement equipment, beginning at the induction port and ending with the back-up filter of the impactor (see Figure 2.9.44.-3). Where appropriate, $F_{m,comp}$ for adjacent stages of the impactor may be combined in order to report the mass fraction collected on a group of stages as a single value.

Determine the cumulative mass-weighted particle-size distribution of the aerosol size-fractionated by the impactor in accordance with the procedure given in general chapter *2.9.18.* Starting at the filter, derive a cumulative mass versus effective cut-off diameter of the respective stages (see Table 2.9.44.-2 for the appropriate cut-off diameters at 15 L/min). Plot the cumulative fraction of active substance versus cut-off diameter in a suitable format, for example logarithmic or log-probability format. Where appropriate, determine by interpolation the fraction either below a given size or between an upper and a lower size limit.

Table 2.9.44.-2. – *Cut-off sizes for Apparatus E at 15 L/min*

Stage	Cut-off diameter (µm)
1	14.1
2	8.61
3	5.39
4	3.30
5	2.08
6	1.36
7	0.98

If necessary, and where appropriate, determine values for the mass median aerodynamic diameter (MMAD) and the geometric standard deviation (GSD), as appropriate.

9. Demonstration of Uniformity of Dosage Units Using Large Samples Sizes

(Ph. Eur. method 2.9.47)

The procedure is intended for, but not limited to, the evaluation of medicinal products that are manufactured using process analytical technology (PAT) methodology.

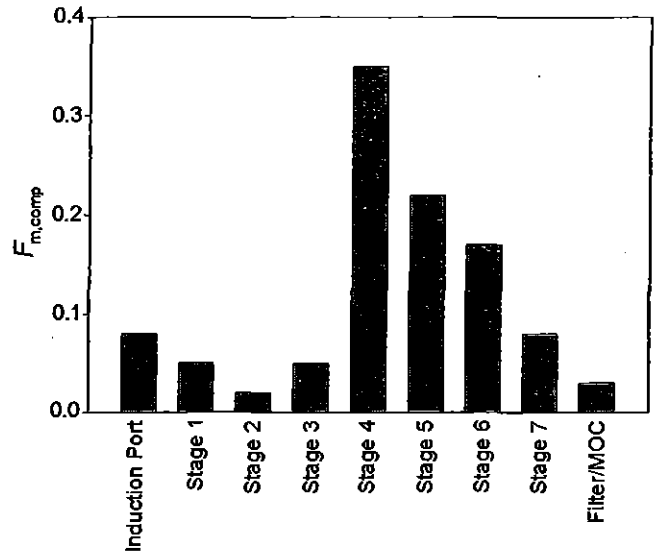


Figure 2.9.44.-3. – *Example of mass fraction of droplets presented in terms of location within the sampling system*

Compliance with general chapter *2.9.40. Uniformity of dosage units* can be demonstrated by the following procedure, when large samples (sample size $n \geq 100$) are evaluated.

Application of this chapter does not constitute a mandatory requirement. It presents 2 alternative tests (Alternative 1 and Alternative 2). Fulfilling the requirements of either of the 2 alternatives is considered as evidence that the medicinal product tested complies with general chapter *2.9.40.* The 2 alternatives are considered equivalent in their demonstration of compliance with general chapter *2.9.40.*

ALTERNATIVE 1 (PARAMETRIC)

Select not fewer than 100 units according to a predefined sampling plan.

The consistency of dosage units is evaluated by content uniformity or mass variation as prescribed in Table 2.9.40.-1. Calculate the acceptance value (*AV*) using the following expression:

$$|M - \overline{X}| + ks$$

for which the terms are defined in Table 2.9.40.-2, but using the sample size-dependent value for k defined in Table 2.9.47.-1.

CRITERIA

Apply the following criteria, unless otherwise specified.

The requirements for dosage form uniformity are met if:

1. the acceptance value (*AV*) is less than or equal to $L1$; and
2. in the calculation of acceptance value (*AV*) under content uniformity or under mass variation, the number of individual dosage units outside $(1 \pm L2 \times 0.01)M$ is less than or equal to $c2$ as defined for a given sample size n in Table 2.9.47.-1.

Unless otherwise specified, $L1$ is 15.0 and $L2$ is 25.0.

Table 2.9.47.-1. is to be interpreted as follows:

— for a sample size of $n = 400$, enter the table at $n \geq 385$: $k = 2.23$ and $c2 = 3$;
— for a sample size of $n = 450$, enter the table at $n \geq 407$: $k = 2.24$ and $c2 = 3$;
— for a sample size of $n = 500$, enter the table at $n \geq 490$: $k = 2.24$ and $c2 = 4$.

ALTERNATIVE 2 (NON-PARAMETRIC)

Select not fewer than 100 units according to a predefined sampling plan.

The consistency of dosage units is evaluated by content uniformity or mass variation as prescribed in Table 2.9.40.-1. Assay individually or weigh the units and calculate individual contents as prescribed in general chapter *2.9.40.* Count the number of individual dosage units with a content outside $(1 \pm L1 \times 0.01)T$ and the number of individual dosage units with a content outside $(1 \pm L2 \times 0.01)T$. Evaluate if the values are within the limits defined in Table 2.9.47.-2.

CRITERIA

Apply the following criteria, unless otherwise specified.

The requirements for dosage form uniformity are met if:

1. the number of individual dosage units outside $(1 \pm L1 \times 0.01)T$ is less than or equal to $c1$; and
2. the number of individual dosage units outside $(1 \pm L2 \times 0.01)T$ is less than or equal to $c2$.

$c1$ and $c2$ for a given sample size n are defined in Table 2.9.47.-2. Unless otherwise specified, $L1$ is 15.0 and $L2$ is 25.0.

Table 2.9.47.-2 is to be interpreted as follows:

— for a sample size of $n = 400$, enter the table at $n \geq 394$: $c1 = 11$ and $c2 = 3$;
— for a sample size of $n = 450$, enter the table at $n \geq 434$: $c1 = 12$ and $c2 = 3$;
— for a sample size of $n = 500$, enter the table at $n \geq 490$: $c1 = 13$ and $c2 = 4$.

10. Content of active ingredient on actuation of the valve test

The following test conditions are for use in Preparations for Inhalation of the British Pharmacopoeia. Specifically the methodology should be applied to Pressurised Inhalation products.

Content of active ingredient delivered by actuation of the valve

Remove the pressurised container from the actuator and remove all labels and markings which may be present on the container with a suitable solvent. Dry the container, replace in its actuator, shake for about 30 seconds and prime the

metering valve as follows. Discharge once to waste, wait for not less than 5 seconds and discharge again to waste. Remove the pressurised container from its actuator, clean the valve stem (internally and externally) and the valve ferrule by washing with a suitable solvent. Dry the complete valve assembly using an air line fitted with an appropriate narrow jet to ensure that all solvent is removed from the inside of the valve stem.

Place a stainless steel base plate that has three legs and a central circular indentation with a hole about 1.5 mm in diameter in a small vessel suitable for shaking and add the volume of solvent specified in the monograph. The size of the vessel is such that when the pressurised inhalation is discharged into the specified volume of solvent as described below the discharge takes place not less than 25 mm below the surface of the solvent.

Shake the pressurised container for about 30 seconds and place it inverted in the vessel. Discharge 10 deliveries below the surface of the solvent actuating the valve at intervals of not less than 5 seconds, maintaining the pressurised container in the vertical plane and discharging the pressurised inhalation through the hole in the centre of the base plate. (It may be necessary because of the nature of the formulation to shake the pressurised container between each actuation of the valve; where this is the case shaking should be carried out without removing the pressurised container from its inverted position in the vessel.) Remove the pressurised container, wash it with the specified solvent and dilute the combined solution and washings to the volume specified in the monograph. Determine the amount of active ingredient by the method described under the Assay and calculate the amount delivered from each actuation of the valve.

The result lies within the range for the content of active ingredient stated in the monograph.

Appendix XIII

A. Particulate Contamination: Sub-visible Particles[1]

(Ph. Eur. method 2.9.19)

Particulate contamination of injections and infusions consists of mobile, undissolved particles, other than gas bubbles, that are unintentionally present. ◊Particulate contamination may originate from various sources and is to be minimised, independent of its type. The level of particulate contamination in parenteral preparations must be controlled.◊

For the determination of particulate contamination, 2 procedures, Method 1 (light obscuration particle count test) and Method 2 (microscopic particle count test), are specified hereinafter. When examining injections and infusions for sub-visible particles, Method 1 is preferably applied. However, it may be necessary to test some preparations by the light obscuration particle count test followed by the microscopic particle count test to reach a conclusion on conformance to the requirements.

Not all parenteral preparations can be examined for sub-visible particles by one or both of these methods. When Method 1 is not applicable, e.g. in case of preparations having reduced clarity or increased viscosity, the test is carried out according to Method 2. Emulsions, colloids, and liposomal preparations are examples. Similarly, products that produce air or gas bubbles when drawn into the sensor may also require ◊specific precautions during sample preparation and/or◊ microscopic particle count testing. If the viscosity of the preparation to be tested is sufficiently high so as to preclude its examination by either test method, a quantitative dilution with an appropriate ◊particle-free◊ diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

The results obtained in examining a discrete unit or group of units for particulate contamination cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans must be developed if valid inferences are to be drawn from observed data to characterise the level of particulate contamination in a large group of units.

METHOD 1. LIGHT OBSCURATION PARTICLE COUNT TEST

Use a suitable apparatus based on the principle of light blockage which allows an automatic determination of the size of particles and the number of particles according to size.

The apparatus is calibrated using suitable certified reference materials consisting of dispersions of spherical particles of known sizes between 10 µm and 25 µm. These standard particles are dispersed in *particle-free water R*. Care must be taken to avoid aggregation of particles during dispersion.

General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filtration equipment used, except for the membrane filters, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse the equipment from top to bottom, outside and then inside, with *particle-free water R*.

Take care not to introduce air bubbles into the preparation to be examined, especially when fractions of the preparation are being transferred to the container in which the determination is to be carried out.

In order to check that the environment is suitable for the test, that the glassware is properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of 5 samples of *particle-free water R*, each of 5 mL, according to the method described below. If the number of particles of 10 µm or greater size exceeds 25 for the combined 25 mL, the precautions taken for the test are not sufficient.

The preparatory steps must be repeated until the environment, glassware and water are suitable for the test.

Method

Mix the contents of the sample by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents. Eliminate gas bubbles by appropriate measures such as allowing the sample to stand for 2 min or sonicating.

For large-volume parenterals, single units are tested.

For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container to obtain a volume of not less than 25 mL; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral administration are reconstituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Remove 4 portions, each of not less than 5 mL, and count the number of particles equal to or greater than 10 µm and 25 µm. Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined.

◊Alternative method

This method is intended to improve the applicability of the test to biological preparations. However, it can be used for any type of preparation.

Clean the outer surfaces of the container(s) using a jet of *particle-free water R*, avoiding any contamination of the contents. Samples are tested under in-use conditions, as directed in the instructions for use (e.g. expelled syringe contents).

For parenteral preparations that have a sufficient volume (i.e. a volume large enough to permit testing), testing of individual units is often preferred.

If the volume is not sufficient, take a suitable number of units, mix each one carefully and thoroughly and then combine the contents in a separate container to obtain the volume required for a single test, depending on the instrument capability and the properties of the sample.

Powders for parenteral administration are reconstituted with *particle-free water R* or with an appropriate particle-free solvent when *particle-free water R* is not suitable.

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

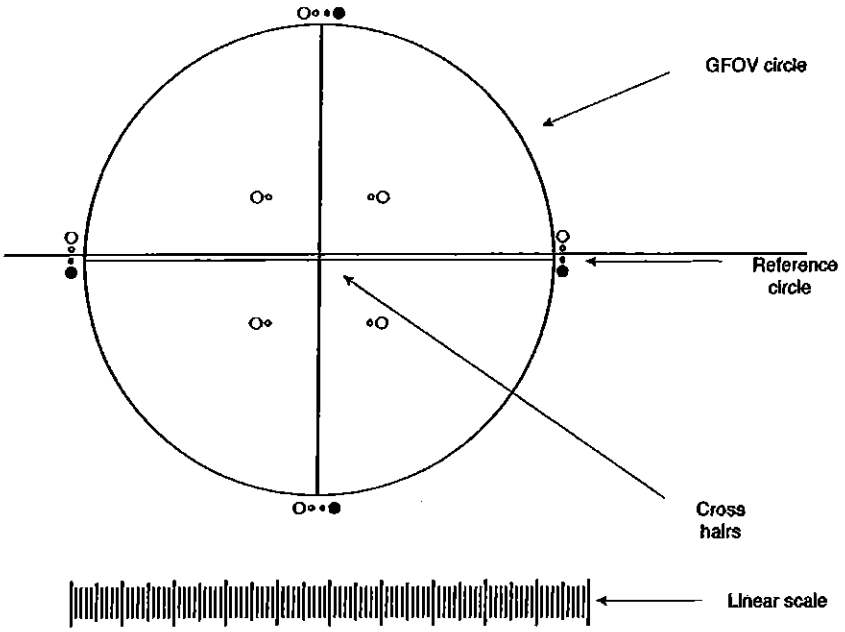

Figure 2.9.19.-1. – *Circular diameter graticule*

Eliminate gas bubbles by appropriate measures such as allowing the sample to stand, applying a gentle vacuum or sonicating. Sonication of preparations containing proteins is not recommended.

The number of test specimens must be adequate to provide a statistically sound assessment. For large- and small-volume parenterals, an adequate volume of sample must be provided for analysis; however, single units may be tested based on a statistically sound sampling plan.

Remove 4 approximately equal portions, typically 5 mL each, and count the number of particles equal to or greater than 10 µm and 25 µm. Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined. Volumes smaller than 5 mL can also be tested, provided that this amount is appropriately justified. In general, for parenteral preparations that do not have a sufficient volume (e.g. less than 25 mL), performing the test using a volume of 1 mL to 5 mL may be acceptable if permitted by the instrument.◊

Evaluation

For preparations supplied in containers with a nominal volume of more than 100 mL, apply the criteria of test 1.A.

For preparations supplied in containers with a nominal volume of less than 100 mL, apply the criteria of test 1.B.

♦For preparations supplied in containers with a nominal volume of 100 mL, apply the criteria of test 1.B.♦

If the average number of particles exceeds the limits, test the preparation by the microscopic particle count test.

Test 1.A – Solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 mL

The preparation complies with the test if the average number of particles present in the units tested does not exceed 25 per millilitre equal to or greater than 10 µm and does not exceed 3 per millilitre equal to or greater than 25 µm.

Test 1.B – Solutions for infusion or solutions for injection supplied in containers with a nominal content of less than 100 mL

The preparation complies with the test if the average number of particles present in the units tested does not exceed 6000 per container equal to or greater than 10 µm and does not exceed 600 per container equal to or greater than 25 µm.

METHOD 2. MICROSCOPIC PARTICLE COUNT TEST

Use a suitable binocular microscope, filter assembly for retaining particulate contamination and membrane filter for examination.

The microscope is equipped with an ocular micrometer calibrated with an objective micrometer, a mechanical stage capable of holding and traversing the entire filtration area of the membrane filter, 2 suitable illuminators to provide episcopic illumination in addition to oblique illumination, and is adjusted to 100 ± 10 magnifications.

The ocular micrometer is a circular diameter graticule (see Figure 2.9.19.-1.) and consists of a large circle divided by crosshairs into quadrants, transparent and black reference circles 10 µm and 25 µm in diameter at 100 magnifications, and a linear scale graduated in 10 µm increments. It is calibrated using a stage micrometer that is certified by either a domestic or an international standard institution. A relative error of the linear scale of the graticule within ± 2 per cent is acceptable. The large circle is designated the graticule field of view (GFOV).

2 illuminators are required. One is an episcopic brightfield illuminator internal to the microscope, the other is an external, focusable auxiliary illuminator adjustable to give reflected oblique illumination at an angle of 10-20°.

The filter assembly for retaining particulate contamination consists of a filter holder made of glass or other suitable material, and is equipped with a vacuum source and a suitable membrane filter.

The membrane filter is of suitable size, black or dark grey in colour, non-gridded or gridded, and 1.0 µm or finer in nominal pore size.

General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filter assembly used, except for the membrane filter, with a warm detergent

solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse both sides of the membrane filter and the equipment from top to bottom, outside and then inside, with *particle-free water R*.

In order to check that the environment is suitable for the test, that the glassware and the membrane filter are properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of a 50 mL volume of *particle-free water R* according to the method described below. If more than 20 particles 10 µm or larger in size or if more than 5 particles 25 µm or larger in size are present within the filtration area, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, membrane filter and water are suitable for the test.

Method

Mix the contents of the samples by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral administration are constituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Wet the inside of the filter holder fitted with the membrane filter with several millilitres of *particle-free water R*. Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If needed, add stepwise a portion of the solution until the entire volume is filtered. After the last addition of solution, begin rinsing the inner walls of the filter holder by using a jet of *particle-free water R*. Maintain the vacuum until the surface of the membrane filter is free from liquid. Place the filter in a Petri dish and allow the filter to air-dry with the cover slightly ajar. After the filter has been dried, place the Petri dish on the stage of the microscope, scan the entire membrane filter under the reflected light from the illuminating device, and count the number of particles that are equal to or greater than 10 µm and the number of particles that are equal to or greater than 25 µm. Alternatively, partial filter count and determination of the total filter count by calculation is allowed. Calculate the mean number of particles for the preparation to be examined.

The particle sizing process with the use of the circular diameter graticule is carried out by transforming mentally the image of each particle into a circle and then comparing it to the 10 µm and 25 µm graticule reference circles. Thereby the particles are not moved from their initial locations within the graticule field of view and are not superimposed on the reference circles for comparison. The inner diameter of the transparent graticule reference circles is used to size white and transparent particles, while dark particles are sized by using the outer diameter of the black opaque graticule reference circles.

In performing the microscopic particle count test do not attempt to size or enumerate amorphous, semi-liquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discolouration on the membrane filter. These materials show little or no surface relief and present a gelatinous or film-like appearance. In such cases the interpretation of enumeration may be aided by testing a sample of the solution by the light obscuration particle count test.

◊*Alternative method*

This method is intended to improve the applicability of the test to biological preparations. However, it can be used for any type of preparation.

Clean the outer surfaces of the container(s) using a jet of *particle-free water R*, avoiding any contamination of the contents. Samples are tested under in-use conditions, as directed in the instructions for use (e.g. expelled syringe contents).

For parenteral preparations that have a sufficient volume (i.e. a volume large enough to permit testing), testing of individual units is often preferred.

If the volume is not sufficient, take a suitable number of units, mix each one carefully and thoroughly and then combine the contents in a separate container to obtain the volume required for a single test, depending on the instrument capability and the properties of the sample.

Powders for parenteral administration are reconstituted with *particle-free water R* or with an appropriate particle-free solvent when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large- and small-volume parenterals, an adequate volume of sample must be provided for analysis; however, single units may be tested based on a statistically sound sampling plan.

Continue as described under Method 2 above, starting from "Wet the inside...".◊

Evaluation

For preparations supplied in containers with a nominal volume of more than 100 mL, apply the criteria of test 2.A.

For preparations supplied in containers with a nominal volume of less than 100 mL, apply the criteria of test 2.B.

♦For preparations supplied in containers with a nominal volume of 100 mL, apply the criteria of test 2.B.♦

Test 2.A – Solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 mL

The preparation complies with the test if the average number of particles present in the units tested does not exceed 12 per millilitre equal to or greater than 10 µm and does not exceed 2 per millilitre equal to or greater than 25 µm.

Test 2.B – Solutions for infusion or solutions for injection supplied in containers with a nominal content of less than 100 mL

The preparation complies with the test if the average number of particles present in the units tested does not exceed 3000 per container equal to or greater than 10 µm and does not exceed 300 per container equal to or greater than 25 µm.

B. Particulate Contamination: Visible Particles

(Ph. Eur. method 2.9.20)

Particulate contamination consists of mobile undissolved substances, other than gas bubbles, unintentionally present in liquid preparations.

The test is intended to provide a simple procedure for the visual assessment of the quality of liquid preparations, if applicable after reconstitution, as regards visible particles.

EQUIPMENT

The equipment (see Figure 2.9.20.-1) consists of a viewing station comprising:

— a matt black panel (A) of appropriate size held in a vertical position;
— a non-glare white panel (B) of appropriate size held in a vertical position next to the black panel;
— a non-glare white panel (C) of appropriate size held in a horizontal position next to (A) and (B);
— a lampholder (D) fitted with a suitable, shaded, white-light source and with a suitable light diffuser (e.g. a viewing illuminator containing two 13 W fluorescent tubes, each 525 mm in length, or an appropriate light-emitting diode (LED) light source). The intensity of illumination at the viewing point is maintained between 2000 lux and 3750 lux, although higher values may be required for coloured glass or plastic containers and for coloured or turbid preparations.

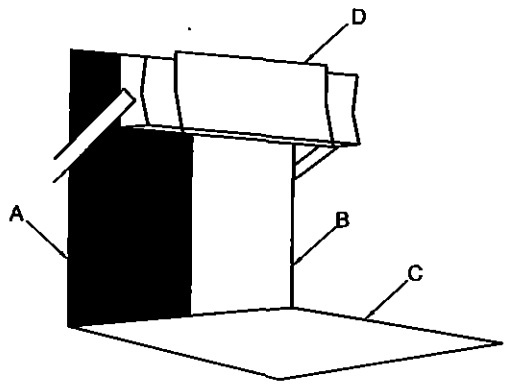

Figure 2.9.20.-1. – *Equipment for visible particles*

METHOD

Adequate visual inspection of the container and contents is necessary, which may require the removal of any adherent labels from the container. Gently swirl or invert the container, ensuring that air bubbles are not introduced, and observe without magnification for about 5 s in front of the white panel (B), although longer observation times may be required for coloured glass or plastic containers and for coloured or turbid preparations. Where inspection in the primary container is not possible, the contents may be transferred for inspection into a sample container that is free from visible particles, taking precautions to prevent contamination during transfer. Repeat the inspection in front of the black panel (A). Record the presence of any visible particles.

Appendix XIV

Biological Assays and Tests

General guidance concerning biological assays and tests is provided in Supplementary Chapter I H.

A. Microbiological Assay of Antibiotics

(Ph. Eur. method 2.7.2)

The potency of an antibiotic is estimated by comparing the inhibition of growth of sensitive micro-organisms produced by known concentrations of the antibiotic to be examined and a reference substance.

The reference substances used in the assays are substances whose activity has been precisely determined with reference to the corresponding international standard or international reference preparation.

The assay must be designed in a way that will permit examination of the validity of the mathematical model on which the potency equation is based. If a parallel-line model is chosen, the 2 log dose-response (or transformed response) lines of the preparation to be examined and the reference preparation must be parallel; they must be linear over the range of doses used in the calculation. These conditions must be verified by validity tests for a given probability, usually $P = 0.05$. Other mathematical models, such as the slope ratio model, may be used provided that proof of validity is demonstrated.

Unless otherwise stated in the monograph, the confidence limits ($P = 0.95$) of the assay for potency are not less than 95 per cent and not more than 105 per cent of the estimated potency.

Carry out the assay by method A or method B.

A. DIFFUSION METHOD

Liquefy a medium suitable for the conditions of the assay and inoculate it at a suitable temperature, for example 48 °C to 50 °C for vegetative forms, with a known quantity of a suspension of micro-organisms sensitive to the antibiotic to be examined, such that clearly defined zones of inhibition of suitable diameter are produced with the concentrations of the antibiotic used for the assay. Immediately pour into Petri dishes or large rectangular dishes a quantity of the inoculated medium to form a uniform layer 2-5 mm thick. Alternatively, the medium may consist of 2 layers, only the upper layer being inoculated.

Store the dishes so that no appreciable growth or death of the micro-organisms occurs before the dishes are used and so that the surface of the medium is dry at the time of use.

Using the solvent and the buffer solution indicated in Table 2.7.2.-1, prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations and presumed to be of equal activity. Apply the solutions to the surface of the medium, for example, in sterile cylinders of porcelain, stainless steel or other suitable material, or in cavities prepared in the agar. The same volume of solution must be added to each cylinder or cavity. Alternatively, use sterile absorbent paper discs of suitable quality; impregnate the discs with the solutions of the reference substance or the solutions of the antibiotic to be examined and place on the surface of the agar.

In order to assess the validity of the assay, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression. In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay as described above must be applied.

Arrange the solutions on each Petri dish or on each rectangular dish according to a statistically suitable design, except for small Petri dishes that cannot accommodate more than 6 solutions, arrange the solutions of the antibiotic to be examined and the solutions of the reference substance in an alternate manner to avoid interaction of the more concentrated solutions.

Incubate at a suitable temperature for about 18 h. A period of diffusion prior to incubation, usually 1-4 h, at room temperature or at about 4 °C, as appropriate, may be used to minimise the effects of the variation in time between the application of the solutions and to improve the regression slope.

Measure the diameters to the nearest 0.1 mm or the areas of the circular inhibition zones to the nearest 0.01 and calculate the potency using appropriate statistical methods.

Use in each assay the number of replications per dose sufficient to ensure the required accuracy and precision. The assay may be repeated and the results combined statistically to obtain the required accuracy and precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

B. TURBIDIMETRIC METHOD

Inoculate a suitable medium with a suspension of the chosen micro-organism having a sensitivity to the antibiotic to be examined such that a sufficiently large inhibition of microbial growth occurs in the conditions of the test. Use a known quantity of the suspension chosen so as to obtain a readily measurable opacity after an incubation period of about 4 h.

Use the inoculated medium immediately after its preparation.

Using the solvent and the buffer solution indicated in Table 2.7.2.-2 prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations presumed to be of equal activity.

In order that the validity of the assay may be assessed, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression. In order to obtain the required linearity, it may be necessary to select from a large number 3 consecutive doses, using corresponding doses for the reference substance and the antibiotic to be examined.

Distribute an equal volume of each of the solutions into identical test-tubes and add to each tube an equal volume of inoculated medium (for example, 1 mL of the solution and 9 mL of the medium). For the assay of tyrothricin add 0.1 mL of the solution to 9.9 mL of inoculated medium.

Prepare at the same time 2 control tubes without antibiotic, both containing the inoculated medium and to one of which is added immediately 0.5 mL of *formaldehyde R*. These tubes are used to set the optical apparatus used to measure the growth.

Place all the tubes, randomly distributed or in a Latin square or randomised block arrangement, in a water-bath or other suitable apparatus fitted with a means of bringing all the tubes rapidly to the appropriate incubation temperature and maintain them at that temperature for 3-4 h, taking precautions to ensure uniformity of temperature and identical incubation time.

After incubation, stop the growth of the micro-organisms by adding 0.5 mL of *formaldehyde R* to each tube or by heat treatment and measure the opacity to 3 significant figures using suitable optical apparatus. Alternatively use a method which allows the opacity of each tube to be measured after exactly the same period of incubation.

Calculate the potency using appropriate statistical methods.

Linearity of the dose-response relationship, transformed or untransformed, is often obtained only over a very limited range. It is this range which must be used in calculating the activity and it must include at least 3 consecutive doses in order to permit linearity to be verified. In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay must be applied.

Use in each assay the number of replications per dose sufficient to ensure the required accuracy and precision. The assay may be repeated and the results combined statistically to obtain the required accuracy and precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

The following section is published for information.

RECOMMENDED MICRO-ORGANISMS

The following text details the recommended micro-organisms and the conditions of use. Other micro-organisms may be used provided that they are shown to be sensitive to the antibiotic to be examined and are used in appropriate media and appropriate conditions of temperature and pH.
The concentrations of the solutions used should be chosen so as to ensure that a linear relationship exists between the logarithm of the dose and the response in the conditions of the test.

Preparation of inocula

Bacillus cereus var. *mycoides*; *Bacillus subtilis*; *Bacillus pumilus*.
Spore suspensions of the organisms to be used as inocula are prepared as follows.

Grow the organism at 35-37 °C for 7 days on the surface of a suitable medium to which has been added 0.001 g/L of *manganese sulfate R*. Using sterile *water R*, wash off the growth, which consists mainly of spores. Heat the suspension at 70 °C for 30 min and dilute to give an appropriate concentration of spores, usually 10×10^6 to 100×10^6 per millilitre. The spore suspensions may be stored for long periods at a temperature not exceeding 4 °C.

Alternatively, spore suspensions may be prepared by cultivating the organisms in medium C at 26 °C for 4-6 days, then adding, aseptically, sufficient *manganese sulfate R* to give a concentration of 0.001 g/L and incubating for a further 48 h. Examine the suspension microscopically to ensure that adequate spore formation has taken place (about 80 per cent) and centrifuge. Re-suspend the sediment in sterile *water R* to give a concentration of 10×10^6 to 100×10^6 spores per millilitre, and then heat to 70 °C for 30 min. Store the suspension at a temperature not exceeding 4 °C.

Buffer solutions

Buffer solutions having a pH between 5.8 and 8.0 are prepared by mixing 50.0 mL of *0.2 M potassium dihydrogen phosphate R* with the quantity of *0.2 M sodium hydroxide* indicated in Table 2.7.2.-3. Dilute with freshly prepared *distilled water R* to produce 200.0 mL.

Table 2.7.2.-3

pH	*0.2 M Sodium hydroxide* (mL)
5.8	3.72
6.0	5.70
6.2	8.60
6.4	12.60
6.6	17.80
6.8	23.65
7.0	29.63
7.2	35.00
7.4	39.50
7.6	42.80
7.8	45.20
8.0	46.80

These buffer solutions are used for all microbiological assays shown in Table 2.7.2.-1 with the exception of bleomycin sulfate and amphotericin B.

For bleomycin sulfate, prepare the buffer solution pH 6.8 as follows: dissolve 6.4 g of *potassium dihydrogen phosphate R* and 18.9 g of *disodium hydrogen phosphate dodecahydrate R* in *water R* and dilute to 1000 mL with *water R*.

For amphotericin B, prepare the 0.2 M phosphate buffer solution pH 10.5 as follows: dissolve 35 g of *dipotassium hydrogen phosphate R* in 900 mL of *water R*, add 20 mL of *1 M sodium hydroxide* and dilute to 1000.0 mL with *water R*.

Culture media

The following media or equivalent media may be used.

Medium A

Peptone	6 g
Pancreatic digest of casein	4 g
Beef extract	1.5 g
Yeast extract	3 g
Glucose monohydrate	1 g
Agar	15 g
Water	to 1000 mL

Medium B

Pancreatic digest of casein	17 g
Papaic digest of soya bean	3 g
Sodium chloride	5 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate	2.5 g
Agar	15 g
Polysorbate 80	10 g
Water	to 1000 mL

The polysorbate 80 is added to the hot solution of the other ingredients after boiling, and immediately before adjusting to volume.

Medium C

Peptone	6 g
Beef extract	1.5 g
Yeast extract	3 g
Sodium chloride	3.5 g
Glucose monohydrate	1 g
Dipotassium hydrogen phosphate	3.68 g
Potassium dihydrogen phosphate	1.32 g
Water	to 1000 mL

Medium D

Heart extract	1.5 g
Yeast extract	1.5 g
Peptone-casein	5 g
Glucose monohydrate	1 g
Sodium chloride	3.5 g
Dipotassium hydrogen phosphate	3.68 g
Potassium dihydrogen phosphate	1.32 g
Potassium nitrate	2 g
Water	to 1000 mL

Medium E

Peptone	5 g
Meat extract	3 g
Disodium hydrogen phosphate,12H_2O	26.9 g
Agar	10 g
Water	to 1000 mL

The disodium hydrogen phosphate is added as a sterile solution after sterilisation of the medium.

Medium F

Peptone	9.4 g
Yeast extract	4.7 g
Beef extract	2.4 g
Sodium chloride	10.0 g
Glucose monohydrate	10.0 g
Agar	23.5 g
Water	to 1000 mL

Medium G

Glycerol	10 g
Peptone	10 g
Meat extract	10 g
Sodium chloride	3 g
Agar	15 g
Water	to 1000 mL

pH 7.0 ± 0.1 after sterilisation.

Medium H

Peptone	5.0 g
Agar	15.0 g
Beef extract powder	3.0 g
Water	to 1000 mL

pH 7.8 - 8.0 adjusted with *0.1 M sodium hydroxide.*

Monographs of the British Pharmacopoeia

The following additional information and guidance apply to monographs of the British Pharmacopoeia.

The required minimum precision for an acceptable assay of any particular antibiotic or preparation is defined in the appropriate monograph in the paragraph on the Assay. This degree of precision is the minimum acceptable for determining that the final product complies with the official requirements. It may be inadequate for a decision about the potency that should be stated on the label or used as the basis for calculating the quantity of an antibiotic to be incorporated in a preparation. In such circumstances, assays of greater precision may be desirable with, for instance, fiducial limits of error of the order of 98 to 102%. With this degree of precision, the lower fiducial limit lies close to the estimated potency. By using this limit, instead of the estimated potency, to assign a potency to the antibiotic either for labelling or for calculating the quantity to be included in a preparation, there is less likelihood of the final preparation subsequently failing to comply with the official requirements for potency.

Culture Media The following media or equivalent media may be used.

Medium I	
D-Glucose	10 g
Tryptone	6 g
Yeast extract*	2 g
Water to produce	1000 mL

Adjust to pH 8.0 with 1M *sodium hydroxide* or 0.1M *orthophosphoric acid.*

(*Ardamine yeast extract supplied by Champlain Industries Inc., Clifton, NJ 07012, USA is suitable.)

Method A. Diffusion Method

* Solution prepared by dissolving 16.73 g of *dipotassium hydrogen orthophosphate* and 0.523 g of *potassium dihydrogen orthophosphate* in about 750 ml of *water*, if necessary adjusting to pH 8.0 with 0.1M *sodium hydroxide* or 0.1M *orthophosphoric acid*, and diluting to 1000 ml with *water*.

B. Immunochemical Methods

(Ph. Eur. method 2.7.1)

Immunochemical methods are based on the selective, reversible and non-covalent binding of antigens by antibodies. These methods are employed to detect or quantify either antigens or antibodies. The formation of an antigen-antibody complex may be detected, and the amount of complex formed may be measured by a variety of techniques. The provisions of this general method apply to immunochemical methods using labelled or unlabelled reagents, as appropriate.

The results of immunochemical methods depend on the experimental conditions and the nature and quality of the reagents used. It is essential to standardise the components of an immunoassay and to use, wherever available, international reference preparations for immunoassays.

The reagents necessary for many immunochemical methods are available as commercial assay kits, that is, a set including reagents (particularly the antigen or the antibody) and materials intended for the *in vitro* estimation of a specified substance as well as instructions for their proper use. The kits are used in accordance with the manufacturers' instructions; it is important to ascertain that the kits are suitable for the analysis of the substance to be examined, with particular reference to selectivity and sensitivity. Guidance concerning immunoassay kits is provided by the World Health Organization, Technical Report Series 658 (1981).

METHODS IN WHICH A LABELLED ANTIGEN OR A LABELLED ANTIBODY IS USED

Methods using labelled substances may employ suitable labels such as enzymes, fluorophores, luminophores and radioisotopes. Where the label is a radioisotope, the method is described as a "radio-immunoassay".

The recommendations for the measurement of radioactivity given in the monograph on *Radiopharmaceutical Preparations (0125)* are applicable to immunoassays involving radioisotopes. All work with radioactive materials must be carried out in conformity with national legislation and internationally accepted codes of practice for protection against radiation hazards.

METHODS IN WHICH AN UNLABELLED ANTIGEN OR ANTIBODY IS USED

Immunoprecipitation methods

Immunoprecipitation methods include flocculation and precipitation reactions. When a solution of an antigen is mixed with its corresponding antibody under suitable conditions, the reactants form flocculating or precipitating aggregates. The ratio of the reactants which gives the shortest flocculation time or the most marked precipitation is called the optimal ratio, and is usually produced by equivalent amounts of antigen and antibody. Immunoprecipitation can be assessed visually or by light-scattering techniques (nephelometric or turbidimetric assay). An increase in sensitivity can be obtained by using antigen- or antibody-coated particles (e.g. latex) as reactants.

In flocculation methods, stepwise dilutions of one of the reactants is usually used whereas, in immunodiffusion (ID) methods, the dilution is obtained by diffusion in a gel medium: concentration gradients of one or both of the reactants are obtained, thus creating zones in the gel medium where the ratio of the reactants favours precipitation. While flocculation methods are performed in tubes, immunodiffusion methods may be performed using different supports such as tubes, plates, slides, cells or chambers.

Where the immunoprecipitating system consists of one antigen combining with its corresponding antibody, the system is referred to as *simple*; when it involves related but not serologically identical reactants, the system is *complex* and where several serologically unrelated reactants are involved, the system is *multiple*.

In *simple diffusion methods*, a concentration gradient is established for only one of the reactants diffusing from an external source into the gel medium containing the corresponding reactant at a comparatively low concentration.

Single radial immunodiffusion (SRID) is a simple quantitative immunodiffusion technique. When the equilibrium between the external and the internal reactant has been established, the circular precipitation area, originating from the site of the external reactant, is directly proportional to the amount of the antigen applied and inversely proportional to the concentration of the antibody in the gel.

In *double diffusion methods*, concentration gradients are established for both reactants. Both antigen and antibody diffuse from separate sites into an initially immunologically neutral gel.

Comparative double diffusion methods Are used for qualitatively comparing various antigens versus a suitable antibody or vice versa. The comparison is based on the presence or absence of interaction between the precipitation patterns. Reactions of identity, non-identity or partial identity of antigens/antibodies can be distinguished.

Immunoelectrophoretic methods

Immunoelectrophoresis (IE) is a qualitative technique combining 2 methods: gel electrophoresis followed by immunodiffusion.

Crossed immunoelectrophoresis Is a modification of the IE method. It is suitable both for qualitative and quantitative analysis. The first part of the procedure is an ordinary gel electrophoresis, after which a longitudinal gel strip, containing the separated fractions to be determined, is cut out and transferred to another plate. The electrophoresis in the second direction is carried out perpendicular to the previous electrophoretic run in a gel containing a comparatively low concentration of antibodies corresponding to the antigens. For a given antibody concentration and gel thickness, the relationship between the area of the respective precipitation peaks and the amount of the corresponding antigen is linear.

Electroimmunoassay Often referred to as *rocket immunoelectrophoresis* is a rapid quantitative method for determining antigens with a charge differing from that of the antibodies or vice versa. The electrophoresis of the antigen to be determined is carried out in a gel containing a comparatively lower concentration of the corresponding antibody. The test material and dilutions of a standard antigen used for calibration are introduced into different wells in the gel. During electrophoresis, migrating peak-shaped precipitation zones originating from the wells are developed. The front of the precipitate becomes stationary when the antigen is no longer in excess. For a given antibody concentration, the relationship between the distance travelled by the precipitate and the amount of antigen applied is linear.

Counter-immunoelectrophoresis Is a rapid quantitative method allowing concentration gradients of external antigen and external antibody to be established in an electric field depending on the different charges. Dilutions of a standard

for calibration and dilutions of the test material are introduced into a row of wells in a gel and a fixed amount of the corresponding reactant is introduced into an opposite row of wells. The titre of the test material may be determined as the highest dilution showing a precipitation line.

A number of modifications of crossed immunoelectrophoresis and electroimmunoassay methods exist.

Other techniques combine separation of antigens by molecular size and serological properties.

Visualisation and characterisation of immunoprecipitation lines

These may be performed by selective or non-selective stains, by fluorescence, by enzyme or isotope labelling or other relevant techniques. Selective staining methods are usually performed for characterisation of non-protein substances in the precipitates.

In translucent gels such as agar or agarose, the precipitation line becomes clearly visible in the gel, provided that the concentration of each of the reactants is appropriate.

VALIDATION OF THE METHOD

Validation criteria

A quantitative immunochemical method is not valid unless:

1) The antibody or antigen does not significantly discriminate between the test and standard. For a labelled reactant, the corresponding reactant does not significantly discriminate between the labelled and unlabelled compound,

2) The method is not affected by the assay matrix, that is, any component of the test sample or its excipients, which can vary between samples. These may include high concentrations of other proteins, salts, preservatives or contaminating proteolytic activity,

3) The limit of quantitation is below the acceptance criteria stated in the individual monograph,

4) The precision of the assay is such that the variance of the results meets the requirements stated in the individual monographs,

5) The order in which the assay is performed does not give rise to systematic errors.

Validation methods

In order to verify these criteria, the validation design includes the following elements:

1) The assay is performed at least in triplicate,

2) The assay includes at least 3 different dilutions of the standard preparation and 3 dilutions of sample preparations of presumed activity similar to the standard preparation,

3) The assay layout is randomised,

4) If the test sample is presented in serum or formulated with other components, the standard is likewise prepared,

5) The test includes the measurement of non-specific binding of the labelled reactant,

6) For displacement immunoassay:

(a) maximum binding (zero displacement) is determined,

(b) dilutions cover the complete response range from values close to non-specific binding to maximum binding, preferably for both standard and test preparations.

STATISTICAL CALCULATION

To analyse the results, response curves for test and standard may be analysed by the methods described in *5.3. Statistical Analysis of Results of Biological Assays and Tests.*

Significant non-parallelism indicates that the antibody or antigen discriminates between test and standard, and the results are not valid.

In displacement immunoassays, the values for non-specific binding and maximum displacement at high test or standard concentration must not be significantly different. Differences may indicate effects due to the matrix, either inhibition of binding or degradation of tracer.

C. Test for Bacterial Endotoxins (LAL Test)[1]

(Bacterial Endotoxins, Ph. Eur. method 2.6.14)

The test for bacterial endotoxins (BET) is used to detect or quantify endotoxins from gram-negative bacteria using amoebocyte lysate from the horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). There are 3 techniques for this test: the gel-clot technique, which is based on gel formation; the turbidimetric technique, based on the development of turbidity after cleavage of an endogenous substrate; and the chromogenic technique, based on the development of colour after cleavage of a synthetic peptide-chromogen complex.

The following 6 methods are described in the present chapter:

Method A.	Gel-clot method: limit test
Method B.	Gel-clot method: quantitative test
Method C.	Turbidimetric kinetic method
Method D.	Chromogenic kinetic method
Method E.	Chromogenic end-point method
Method F.	Turbidimetric end-point method

Proceed by any of the 6 methods for the test. In the event of doubt or dispute, the final decision is made based upon method A unless otherwise indicated in the monograph.

The test is carried out in a manner that avoids endotoxin contamination.

1. APPARATUS

Depyrogenate all glassware and other heat-stable apparatus in a hot-air oven using a validated process. A commonly used minimum time and temperature is 30 min at 250 °C.

If employing plastic apparatus, such as microtitre plates and pipette tips for automatic pipetters, use apparatus shown to be free of detectable endotoxin and which does not interfere in the test.

NOTE: in this chapter, the term 'tube' includes all types of receptacles, for example microtitre plate wells.

2. REAGENTS, TEST SOLUTIONS

(1) Amoebocyte lysate

Amoebocyte lysate is a lyophilised product obtained from amoebocyte lysate from the horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). This reagent refers only to a product manufactured in accordance with the regulations of the competent authority.

NOTE: amoebocyte lysate reacts with some β-glucans in addition to endotoxins. Amoebocyte lysate preparations which do not react with glucans are available; they are prepared by removing from amoebocyte lysate the G factor, which reacts with glucans, or by inhibiting the G factor reacting system of amoebocyte lysate. These

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

preparations may be used for endotoxin testing in the presence of glucans.

(2) Lysate solution
Dissolve amoebocyte lysate in water for BET or in a buffer, as recommended by the lysate manufacturer, by gentle stirring. Store the reconstituted lysate, refrigerated or frozen, as indicated by the manufacturer.

(3) Water for BET (water for bacterial endotoxins test)
Water for injections R or water produced by other procedures that shows no reaction with the lysate employed at the detection limit of the reagent.

3. PREPARATION OF THE STANDARD ENDOTOXIN STOCK SOLUTION

The standard endotoxin stock solution is prepared from an endotoxin reference standard that has been calibrated against the International Standard, for example *endotoxin standard BRP.*

Endotoxin is expressed in International Units (IU).
The equivalence in IU of the International Standard is stated by the World Health Organization.

NOTE: one International Unit (IU) of endotoxin is equal to one Endotoxin Unit (E.U.).

Follow the specifications in the package leaflet and on the label for preparation and storage of the standard endotoxin stock solution.

4. PREPARATION OF THE STANDARD ENDOTOXIN SOLUTIONS

After vigorously mixing the standard endotoxin stock solution, prepare appropriate serial dilutions of this solution using water for BET.

Use the solutions as soon as possible to avoid loss of activity by adsorption.

5. PREPARATION OF THE TEST SOLUTIONS

Prepare the test solutions by dissolving or diluting active substances or medicinal products using water for BET. Some substances or preparations may be more appropriately dissolved or diluted in other aqueous solutions. If necessary, adjust the pH of the test solution (or dilution thereof) so that the pH of the mixture of the lysate and test solution falls within the pH range specified by the lysate manufacturer, usually 6.0 to 8.0. The pH may be adjusted by the use of acid, base or a suitable buffer, as recommended by the lysate manufacturer. Acids and bases may be prepared from concentrates or solids with water for BET in containers free of detectable endotoxin. Buffers must be validated to be free of detectable endotoxin and interfering factors.

6. DETERMINATION OF THE MAXIMUM VALID DILUTION

The Maximum Valid Dilution (MVD) is the maximum allowable dilution of a sample at which the endotoxin limit can be determined. Determine the MVD using the following formulae:

$$MVD = \frac{\text{endotoxin limit} \times \text{concentration of test solution}}{\lambda}$$

Endotoxin limit The endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to:

$$\frac{K}{M}$$

K = threshold pyrogenic dose of endotoxin per kilogram of body mass,
M = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, M is the maximum total dose administered in a single hour period.

The endotoxin limit for active substances administered parenterally is specified in units such as IU/mL, IU/mg, IU/Unit of biological activity, etc., in monographs.

Concentration of test solution:
— mg/mL if the endotoxin limit is specified by mass (IU/mg),
— Units/mL if the endotoxin limit is specified by unit of biological activity (IU/Unit),
— mL/mL if the endotoxin limit is specified by volume (IU/mL).

λ = the labelled lysate sensitivity in the gel-clot technique (IU/mL) or the lowest concentration used in the standard curve of the turbidimetric or chromogenic techniques.

7. GEL-CLOT TECHNIQUE (METHODS A AND B)

The gel-clot technique allows detection or quantification of endotoxins and is based on clotting of the lysate in the presence of endotoxins. The minimum concentration of endotoxins required to cause the lysate to clot under standard conditions is the labelled lysate sensitivity.
To ensure both the precision and validity of the test, confirm the labelled lysate sensitivity and perform the test for interfering factors as described under 1. Preparatory testing.

1. PREPARATORY TESTING

(i) Confirmation of the labelled lysate sensitivity
Confirm in 4 replicates the labelled sensitivity λ, expressed in IU/mL, of the lysate solution prior to use in the test. Confirmation of the lysate sensitivity is carried out when a new lot of lysate is used or when there is any change in the test conditions which may affect the outcome of the test.

Prepare standard solutions of at least 4 concentrations equivalent to 2λ, λ, 0.5λ and 0.25λ by diluting the standard endotoxin stock solution with water for BET.

Mix a volume of the lysate solution with an equal volume of 1 of the standard solutions (such as 0.1 mL aliquots) in each tube. When single test vials or ampoules containing lyophilised lysate are employed, add solutions of standards directly to the vial or ampoule. Incubate the reaction mixture for a constant period according to the recommendations of the lysate manufacturer (usually at 37 ± 1 °C for 60 ± 2 min), avoiding vibration. Test the integrity of the gel: for tubes, take each tube in turn directly from the incubator and invert it through approximately 180° in one smooth motion. If a firm gel has formed that remains in place upon inversion, record the result as positive. A result is negative if an intact gel is not formed.

The test is considered valid when the lowest concentration of the standard solutions shows a negative result in all replicate tests.

Table 2.6.14.-1

Solution	Endotoxin concentration/Solution to which endotoxin is added	Diluent	Dilution factor	Endotoxin concentration	Number of replicates
A	None/Test solution	-	-	-	4
B	2λ/Test solution	Test solution	1	2λ	4
			2	1λ	4
			4	0.5λ	4
			8	0.25λ	4
C	2λ/Water for BET	Water for BET	1	2λ	2
			2	1λ	2
			4	0.5λ	2
			8	0.25λ	2
D	None/Water for BET	-	-	-	2

Solution A = solution of the preparation being examined that is free of detectable endotoxins.
Solution B = test for interference.
Solution C = control of the labelled lysate sensitivity.
Solution D = negative control (water for BET).

The end-point is the lowest concentration in the series of decreasing concentrations of standard endotoxin that clots the lysate. Determine the geometric mean end-point concentration by calculting the mean of the logarithms of the end-point concentrations of the 4 dilution series, take the antilogarithm of this value, as indicated by the following expression:

$$\text{Geometric mean end-point concentration} = \text{antilog}\frac{\sum e}{f}$$

$\sum e$ = sum of the $\log_{10}$ end-point concentrations of the dilution series used,

f = number of replicates.

The geometric mean end-point concentration is the measured sensitivity of the lysate solution (IU/mL). If this is not less than 0.5λ and not more than 2λ, the labelled sensitivity is confirmed and is used in the tests performed with this lysate.

(ii) Test for interfering factors

Prepare solutions A, B, C and D as shown in Table 2.6.14.-1, and use the test solutions at a dilution less than the MVD, not containing any detectable endotoxins, operating as described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

The geometric mean end-point concentrations of solutions B and C are determined using the expression described in 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

The test for interfering factors must be repeated when any changes are made to the experimental conditions that are likely to influence the result of the test.

The test is considered valid when all replicates of solutions A and D show no reaction and the result of solution C confirms the labelled lysate sensitivity.

If the sensitivity of the lysate determined with solution B is not less than 0.5λ and not greater than 2λ, the test solution does not contain interfering factors under the experimental conditions used. Otherwise, the test solution interferes with the test.

If the preparation being examined interferes with the test at a dilution less than the MVD, repeat the test for interfering factors using a greater dilution, not exceeding the MVD. The use of a more sensitive lysate permits a greater dilution of the preparation being examined and this may contribute to the elimination of interference.

Interference may be overcome by suitable validated treatment, such as filtration, neutralisation, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, repeat the test for interfering factors using the preparation being examined to which the standard endotoxin has been added and which has then been submitted to the chosen treatment.

2. LIMIT TEST (METHOD A)

(i) Procedure

Prepare solutions A, B, C and D as shown in Table 2.6.14.-2, and perform the test on these solutions following the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

Table 2.6.14.-2

Solution	Endotoxin concentration/Solution to which endotoxin is added	Number of replicates
A	None/Diluted test solution	2
B	2λ/Diluted test solution	2
C	2λ/Water for BET	2
D	None/Water for BET	2

Prepare solution A and solution B (positive product control) using a dilution not greater than the MVD and treatments as described in 1. Preparatory testing, (ii) Test for interfering factors. Solutions B and C (positive controls) contain the standard endotoxin at a concentration corresponding to twice the labelled lysate sensitivity. Solution D (negative control) consists of water for BET.

(ii) Interpretation

The test is considered valid when both replicates of solution B and C are positive and those of solution D are negative.

When a negative result is found for both replicates of solution A, the preparation being examined complies with the test.

When a positive result is found for both replicates of solution A, the preparation being examined does not comply with the test.

When a positive result is found for one replicate of solution A and a negative result is found for the other, repeat the test. In the repeat test, the preparation being examined complies with the test if a negative result is found for both replicates of solution A. The preparation does not comply with the test if a positive result is found for one or both replicates of solution A.

Table 2.6.14.-3

Solution	Endotoxin concentration/Solution to which endotoxin is added	Diluent	Dilution factor	Endotoxin concentration	Number of replicates
A	None/Test solution	Water for BET	1	-	2
			2	-	2
			4	-	2
			8	-	2
B	2λ/Test solution		1	2λ	2
C	2λ/Water for BET	Water for BET	1	2λ	2
			2	1λ	2
			4	0.5λ	2
			8	0.25λ	2
D	None/Water for BET	-	-	-	2

Solution A = test solution at the dilution, not exceeding the MVD, with which the test for interfering factors was carried out. Subsequent dilution of the test solution must not exceed the MVD. Use water for BET to make a dilution series of 4 tubes containing the test solution at concentrations of 1, 1/2, 1/4 and 1/8, relative to the dilution used in the test for interfering factors. Other dilutions up to the MVD may be used as appropriate.
Solution B = solution A containing standard endotoxin at a concentration of 2λ (positive product control).
Solution C = a dilution series of 4 tubes of water for BET containing the standard endotoxin at concentrations of 2λ, λ, 0.5λ and 0.25λ.
Solution D = water for BET (negative control).

However, if the preparation does not comply with the test at a dilution less than the MVD, the test may be repeated using a greater dilution, not exceeding the MVD.

3. QUANTITATIVE TEST (METHOD B)

(i) Procedure

The test quantifies bacterial endotoxins in the test solution by titration to an end-point. Prepare solutions A, B, C and D as shown in Table 2.6.14.-3, and test these solutions according to the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

(ii) Calculation and interpretation

The test is considered valid when the following 3 conditions are met:

(a) both replicates of solution D (negative control) are negative,

(b) both replicates of solution B (positive product control) are positive,

(c) the geometric mean end-point concentration of solution C is in the range of 0.5λ to 2λ.

To determine the endotoxin concentration of solution A, calculate the end-point concentration for each replicate, by multiplying each end-point dilution factor by λ.

The endotoxin concentration in the test solution is the end-point concentration of the replicates. If the test is conducted with a diluted test solution, calculate the concentration of endotoxin in the original solution by multiplying the result by the dilution factor.

If none of the dilutions of the test solution is positive in a valid test, report the endotoxin concentration as less than λ (or, if a diluted sample was tested, report as less than the lowest dilution factor of the sample × λ). If all dilutions are positive, the endotoxin concentration is reported as equal to or greater than the largest dilution factor multiplied by λ (e.g. in Table 2.6.14.-3, the initial dilution factor × 8 × λ).

The preparation being examined meets the requirements of the test if the endotoxin concentration in both replicates is less than that specified in the monograph.

8. PHOTOMETRIC QUANTITATIVE TECHNIQUES (METHODS C, D, E AND F)

1. TURBIDIMETRIC TECHNIQUE (METHODS C AND F)

This technique is a photometric test to measure the increase in turbidity. Based on the test principle employed, this technique may be classified as being either the end-point-turbidimetric test or the kinetic-turbidimetric test.

The end-point-turbidimetric test (Method F) is based on the quantitative relationship between the endotoxin concentration and the turbidity (absorbance or transmission) of the reaction mixture at the end of an incubation period.

The kinetic-turbidimetric test (Method C) is a method to measure either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance or transmission, or the rate of turbidity development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually 37 ± 1 °C).

2. CHROMOGENIC TECHNIQUE (METHODS D AND E)

This technique is used to measure the chromophore released from a suitable chromogenic peptide by the reaction of endotoxins with the lysate. Depending on the test principle employed, this technique may be classified as being either the end-point-chromogenic test or the kinetic-chromogenic test.

The end-point-chromogenic test (Method E) is based on the quantitative relationship between the endotoxin concentration and the quantity of chromophore released at the end of an incubation period.

The kinetic-chromogenic test (Method D) measures either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance, or the rate of colour development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually 37 ± 1 °C).

3. PREPARATORY TESTING

To assure the precision or validity of the turbidimetric and chromogenic techniques, preparatory tests are conducted to show that the criteria for the standard curve are satisfied and that the test solution does not interfere with the test.

Validation of the test method is required when any changes are made to the experimental conditions that are likely to influence the result of the test.

(i) Assurance of criteria for the standard curve

The test must be carried out for each lot of lysate reagent.

Using the standard endotoxin solution, prepare at least 3 endotoxin concentrations within the range indicated by the lysate manufacturer to generate the standard curve. Perform

the test using at least 3 replicates of each standard endotoxin solution as recommended by the lysate manufacturer (volume ratios, incubation time, temperature, pH, etc.).

If the desired range is greater than 2 $\log_{10}$ in the kinetic methods, additional standards must be included to bracket each $\log_{10}$ increase in the range of the standard curve.

The absolute value of the correlation coefficient, $|r|$, must be greater than or equal to 0.980, for the range of endotoxin concentrations set up.

(ii) Test for interfering factors

Select an endotoxin concentration at or near the middle of the endotoxin standard curve.

Prepare solutions A, B, C and D as shown in Table 2.6.14.-4. Perform the test on at least 2 replicates of these solutions as recommended by the lysate manufacturer (volume of test solution and lysate solution, volume ratio of test solution to lysate solution, incubation time, etc.).

Table 2.6.14.-4

Solution	Endotoxin concentration	Solution to which endotoxin is added	Number of replicates
A	None	Test solution	Not less than 2
B	Middle concentration of the standard curve	Test solution	Not less than 2
C	At least 3 concentrations (lowest concentration is designated λ)	Water for BET	Each concentration not less than 2
D	None	Water for BET	Not less than 2

Solution A = test solution, that may be diluted not to exceed the MVD.
Solution B = preparation to be examined at the same dilution as solution A, containing added endotoxin at a concentration equal to or near the middle of the standard curve.
Solution C = standard endotoxin solution at the concentrations used in the validation of the method as described under 3. Preparatory testing, (i) Assurance of criteria for the standard curve (positive controls).
Solution D = water for BET (negative control).

The test is considered valid when the following conditions are met:

- the absolute value of the correlation coefficient of the standard curve generated using solution C is greater than or equal to 0.980;
- the result with solution D does not exceed the limit of the blank value required in the description of the lysate reagent employed, or it is less than the endotoxin detection limit of the lysate reagent employed.

Calculate the mean recovery of the added endotoxin by subtracting the mean endotoxin concentration in the solution (if any) (solution A, Table 2.6.14.-4) from that in the solution containing the added endotoxin (solution B, Table 2.6.14.-4).

The test solution is considered free of interfering factors if under the conditions of the test, the measured concentration of the endotoxin added to the test solution is within 50-200 per cent of the known added endotoxin concentration, after subtraction of any endotoxin detected in the solution without added endotoxin.

When the endotoxin recovery is out of the specified range, the test solution is considered to contain interfering factors. Repeat the test using a greater dilution, not exceeding the MVD. Furthermore, interference of the test solution or diluted test solution not to exceed the MVD may be eliminated by suitable validated treatment, such as filtration, neutralisation, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, repeat the test for interfering factors using the preparation being examined to which the standard endotoxin has been added and which has then been submitted to the chosen treatment.

4. TEST

(i) Procedure

Follow the procedure described in 3. Preparatory testing, (ii) Test for interfering factors.

(ii) Calculation

Calculate the endotoxin concentration of each replicate of solution A using the standard curve generated by the positive control solution C.

The test is considered valid when the following 3 requirements are met:

(1) the results obtained with solution C comply with the requirements for validation defined under 3. Preparatory testing, (i) Assurance of criteria for the standard curve,

(2) the endotoxin recovery, calculated from the endotoxin concentration found in solution B after subtracting the endotoxin concentration found in solution A, is within the range of 50-200 per cent,

(3) the result obtained with solution D (negative control) does not exceed the limit of the blank value required in the description of the lysate employed, or it is less than the endotoxin detection limit of the lysate reagent employed.

(iii) Interpretation

The preparation being examined complies with the test if the mean endotoxin concentration of the replicates of solution A, after correction for dilution and concentration, is less than the endotoxin limit for the product.

Guidelines on the test for bacterial endotoxins are given in general chapter 5.1.10.

2.6.32. Test for Bacterial Endotoxins using Recombinant Factor C

(Ph. Eur. general text 2.6.32)

The test for bacterial endotoxins using recombinant factor C (rFC) is carried out to quantify endotoxins from gram-negative bacteria. It is performed using rFC based on the gene sequence of the horseshoe crab (*Limulus polyphemus, Tachypleus tridentatus, Tachypleus gigas* or *Carcinoscorpius rotundicauda*), using a fluorimetric method.

The test is carried out in a manner that avoids bacterial endotoxin contamination.

1. EQUIPMENT

Depyrogenate all glassware and other heat-stable equipment in a dry-heat oven using a validated process. A commonly used minimum time and temperature is 30 min at 250 °C. Where plastic equipment (such as microtitre plates and pipette tips for automatic pipettes) is employed, it must be shown to be free of detectable endotoxin and not to interfere with the test.

2. REAGENTS

Reagents

Recombinant factor C is based on the gene sequence of the horseshoe crab (*Limulus polyphemus, Tachypleus tridentatus, Tachypleus gigas* or *Carcinoscorpius rotundicauda*). All reagents, including the fluorogenic substrate and assay buffer, must be free of detectable endotoxin.

Reagent solutions
If necessary, prepare the reagents according to the test kit manufacturer's instructions. Store the reagents, refrigerated or frozen, as indicated by the manufacturer.

Water for BET (water for bacterial endotoxins test)
Water for injections R or water produced by other procedures that shows no reaction with the reagent employed at the detection limit of the reagent.

3. PREPARATION OF THE STANDARD ENDOTOXIN STOCK SOLUTION

The standard endotoxin stock solution is prepared from an endotoxin reference standard that has been calibrated against the International Standard, for example *endotoxin standard BRP.*

Endotoxin is expressed in International Units (IU).
The equivalence in IU of the International Standard is stated by the World Health Organization.

NOTE: 1 International Unit (IU) of endotoxin is equal to 1 Endotoxin Unit (EU).

Follow the specifications in the package leaflet and on the label for preparation and storage of the standard endotoxin stock solution.

4. PREPARATION OF THE STANDARD ENDOTOXIN SOLUTIONS

After vigorously mixing the standard endotoxin stock solution, prepare appropriate serial dilutions of this solution using water for BET.

Use the solutions as soon as possible to avoid loss of activity by adsorption.

5. PREPARATION OF THE TEST SOLUTIONS

Prepare the test solutions by dissolving or diluting active substances or medicinal products using water for BET. Some substances or preparations may be more appropriately dissolved or diluted in other aqueous solutions. If necessary, adjust the pH of the test solution (or dilution thereof) so that the pH of the mixture of the reagent(s) and test solution falls within the pH range specified by the test kit manufacturer, usually 6.0 to 8.0. The pH may be adjusted by the use of acid, base or a suitable buffer, as recommended by the test kit manufacturer. Acids and bases may be prepared from concentrates or solids with water for BET in containers free of detectable endotoxin. Buffers must be validated to be free of detectable endotoxin and interfering factors.

6. DETERMINATION OF THE MAXIMUM VALID DILUTION

The maximum valid dilution (MVD) is the maximum allowable dilution of a sample at which the endotoxin limit can be determined. Determine the MVD using the following formula:

$$\frac{\textit{endotoxin limit} \times \textit{concentration of test solution}}{\lambda}$$

Endotoxin limit The endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to:

$$\frac{K}{M}$$

K = threshold pyrogenic dose of endotoxin per kilogram of body mass;
M = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, M is the maximum total dose administered in a single hour period.

The endotoxin limit for active substances administered parenterally is specified in units such as IU/mL, IU/mg, IU/Unit of biological activity, etc., in monographs.

Concentration of test solution:
- mg/mL if the endotoxin limit is specified by mass (IU/mg);
- Units/mL if the endotoxin limit is specified by unit of biological activity (IU/Unit);
- mL/mL if the endotoxin limit is specified by volume (IU/mL).

λ = the lowest concentration used in the standard curve.

7. FLUORIMETRIC QUANTITATIVE TECHNIQUE

This technique is used to measure the fluorescence (relative fluorescence units; RFU) emitted by a fluorescent substrate (reagent) after cleavage by endotoxin-activated factor C. It is used as an end-point-fluorescent test.

The end-point-fluorescent test is based on the quantitative relationship between the endotoxin concentration and the fluorescence of the reagent mixture at the end of the incubation period, expressed for example as ΔRFU:

$$\Delta RFU = RFU_{t_{end\text{-}point}} - RFU_{t_0}$$

$RFUt_{end\text{-}point}$ = fluorescence of the reagent mixture at the end of the incubation period;
$RFUt_0$ = fluorescence of the reagent mixture at the start of the incubation period.

The test is carried out at the incubation temperature recommended by the test kit manufacturer (usually 37 ± 1 °C).

8. PREPARATORY TESTING

Preparatory tests are conducted to ensure that the fluorometric technique is valid. These tests demonstrate that the criteria for the standard curve are satisfied (8-1) and that the test solution does not interfere with the test (8-2).

Validation of the test method is required when any changes are made to the experimental conditions that are likely to influence the result of the test.

8-1 ASSURANCE OF CRITERIA FOR THE STANDARD CURVE

The test must be carried out for each lot of recombinant factor C reagent.

Instrument sensitivity must be adjusted in accordance with the recommendations of the test kit manufacturer.

Using the standard endotoxin solution, prepare at least 3 endotoxin concentrations within the range indicated by the test kit manufacturer to generate the standard curve. If the desired range exceeds the range indicated by the manufacturer by more than 2 $\log_{10}$, additional standards must be included to bracket each log increase in the range. Perform the test using at least 3 replicates of each standard endotoxin solution as recommended by the manufacturer (volume ratios, incubation time, temperature, pH, etc.).

The absolute value of the correlation coefficient, $|r|$, must be greater than or equal to 0.980, for the range of endotoxin concentrations prepared.

8-2 INTERFERING FACTORS

As factor G is absent from the test kit, false-positive results due to β-glucan activation are not expected to occur. This must be taken into account when the method is compared to other bacterial endotoxin quantification methods.

Select an endotoxin concentration at or near the middle of the endotoxin standard curve.

Prepare solutions A, B, C and D as shown in Table 2.6.32.-1. Perform the test on at least 2 replicates of these solutions as recommended by the test kit manufacturer (volume of test solution and reagent test kit mixture, volume ratio of test solution to reagent test kit mixture, incubation time, etc.).

Table 2.6.32.-1

Solution	Endotoxin concentration	Solution to which endotoxin is added	Number of replicates
A	None	Test solution	Not less than 2
B	Middle concentration of the standard curve	Test solution	Not less than 2
C	At least 3 concentrations (lowest concentration is designated λ)	Water for BET	Each concentration not less than 2
D	None	Water for BET	Not less than 2

Solution A = test solution, which may be diluted but not exceeding the MVD.
Solution B (positive product control) = preparation to be examined at the same dilution as solution A, containing added endotoxin at a concentration equal to or near the middle of the standard curve
Solution C = standard endotoxin solution at the concentrations used in the validation of the method as described in section 8-1.
Solution D (negative control) = water for BET.

The test is considered valid when the following conditions are met:

- the absolute value of the correlation coefficient of the standard curve generated using solution C is greater than or equal to 0.980;
- the result with solution D does not exceed the limit of the blank value required in the description of the reagent mixture employed, or it is less than the endotoxin detection limit of the rFC employed.

Calculate the mean recovery of the added endotoxin by subtracting the mean endotoxin concentration in the solution (if any) (solution A, Table 2.6.32.-1) from that in the solution containing the added endotoxin (solution B, Table 2.6.32.-1).

The test solution is considered free of interfering factors if, under the conditions of the test, the measured concentration of the endotoxin added to the test solution is within 50-200 per cent of the known added endotoxin concentration, after subtraction of any endotoxin detected in the solution without added endotoxin.

When the endotoxin recovery is outside the specified range, the test solution is considered to contain interfering factors. Repeat the test using a greater dilution, not exceeding the MVD. Furthermore, interference of the test solution or diluted test solution (not exceeding the MVD) may be eliminated by suitable validated treatment, such as filtration, neutralisation, dialysis, heat treatment or endotoxin-specific binding steps (enrichment of endotoxin from the test solution prior to detection in the absence of the interfering matrix). To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, repeat the test for interfering factors using the preparation being examined to which the standard endotoxin has been added and which has then been submitted to the chosen treatment.

9. TEST

9-1 PROCEDURE

Follow the procedure described in section 8-2.

9-2 CALCULATION

Calculate the endotoxin concentration of each replicate of solution A using the standard curve generated by the standard endotoxin solution C.

The test is considered valid when the following 3 requirements are met:

(1) the results obtained with solution C comply with the requirements for validation defined in section 8-1;

(2) the endotoxin recovery, calculated from the endotoxin concentration found in solution B after subtracting the endotoxin concentration found in solution A, is within the range of 50-200 per cent;

(3) the result obtained with solution D (negative control) does not exceed the limit of the blank value required in the description of the reagent mixture employed, or it is less than the endotoxin detection limit of the rFC employed.

9-3 INTERPRETATION

The preparation being examined complies with the test if the mean endotoxin concentration of the replicates of solution A, after correction for dilution and concentration, is less than the endotoxin limit for the product.

Guidelines on the test for bacterial endotoxins are given in general chapter 5.1.10.

D. Test for Pyrogens

(Ph. Eur. method 2.6.8)

The test consists of measuring the rise in body temperature evoked in rabbits by the intravenous injection of a sterile solution of the substance to be examined.

Selection of animals

Use healthy, adult rabbits of either sex weighing not less than 1.5 kg, fed a complete and balanced diet not containing antibiotics, and not showing loss of body mass during the week preceding the test. A rabbit is not to be used in a pyrogen test if:

a) it has been used in a negative pyrogen test in the preceding 3 days; or

b) it has been used in the preceding 3 weeks in a pyrogen test in which the substance under examination failed to pass the test.

Animals' quarters

Keep the rabbits individually in a quiet area with a uniform appropriate temperature. Withhold food from the rabbits overnight and until the test is completed; withhold water during the test. Carry out the test in a quiet room where there is no risk of disturbance exciting the animals and in which the room temperature is within 3 °C of that of the rabbits' living quarters, or in which the rabbits have been kept for at least 18 h before the test.

Materials

Thoroughly wash all glassware, syringes and needles with water for injections and heat in a hot-air oven at 250 °C for 30 min or at 200 °C for 1 h.

Retaining boxes
The retaining boxes for rabbits whose temperature is being measured by an electrical device are made in such a way that the animals are retained only by loosely fitting neck-stocks; the rest of the body remains relatively free so that the rabbits may sit in a normal position. They are not restrained by straps or other similar methods that may harm the animal. The animals are put into the boxes not less than 1 h before the 1st recording of the temperature and remain in them throughout the test.

Thermometers
Use a thermometer or electrical device that indicates the temperature with a resolution of 0.1 °C and insert into the rectum of the rabbit to a depth of about 5 cm. The depth of insertion is constant for any 1 rabbit in any 1 test. When an electrical device is used it may be left in position throughout the test.

Preliminary test
After selection of the animals, 1-3 days before testing the product to be examined, treat those animals that have not been used during the previous 2 weeks by intravenous injection of 10 mL per kilogram of body mass of a pyrogen-free 9 g/L solution of *sodium chloride R* warmed to about 38.0 °C. Record the temperatures of the animals, beginning at least 90 min before injection and continuing for 3 h after the injection of the solution. Any animal showing a temperature variation greater than 0.6 °C is not used in the main test.

Main test
Carry out the test using a group of 3 rabbits.

Preparation and injection of the product Warm the liquid to be examined to approximately 38.0 °C before the injection. The product to be examined may be dissolved in, or diluted with, a pyrogen-free 9 g/L solution of *sodium chloride R* or another prescribed liquid. Inject the solution slowly into the marginal vein of the ear of each rabbit over a period not exceeding 4 min, unless otherwise prescribed in the monograph. The amount of the product to be injected varies according to the product to be examined and is prescribed in the monograph. The volume injected is not less than 0.5 mL per kilogram and not more than 10 mL per kilogram of body mass.

Determination of the initial and maximum temperatures The 'initial temperature' of each rabbit is the mean of 2 temperature readings recorded for that rabbit at an interval of 30 min in the 40 min immediately preceding the injection of the product to be examined. The 'maximum temperature' of each rabbit is the highest temperature recorded for that rabbit in the 3 h after the injection. Record the temperature of each rabbit at intervals of not more than 30 min, beginning at least 90 min before the injection of the product to be examined and continuing 3 h after the injection. The difference between the maximum temperature and the initial temperature of each rabbit is taken to be its response. When this difference is negative, the result is counted as a zero response.

Rabbits showing a temperature variation greater than 0.2 °C between 2 successive readings in the determination of the initial temperature are withdrawn from the test. In any 1 test, only rabbits having initial temperatures that do not differ from one another by more than 1 °C are used. All rabbits having an initial temperature higher than 39.8 °C or less than 38.0 °C are withdrawn from the test.

Interpretation of results
Having carried out the test 1st on a group of 3 rabbits, repeat if necessary on further groups of 3 rabbits to a total of 4 groups, depending on the results obtained. If the summed response of the 1st group does not exceed the figure given in the 2nd column of Table 2.6.8.-1, the substance passes the test. If the summed response exceeds the figure given in the 2nd column of the table but does not exceed the figure given in the 3rd column of the table, repeat the test as indicated above. If the summed response exceeds the figure given in the 3rd column of the table, the product fails the test.

Table 2.6.8.-1

Number of rabbits	Product passes if summed response does not exceed	Product fails if summed response exceeds
3	1.15 °C	2.65 °C
6	2.80 °C	4.30 °C
9	4.45 °C	5.95 °C
12	6.60 °C	6.60 °C

Rabbits used in a test for pyrogens where the mean rise in the rabbits' temperature has exceeded 1.2 °C are permanently excluded.

In accordance with the provisions of the European Convention for the Protection of Vertebrate Animals used for Experimental and Other Scientific Purposes, tests must be carried out in such a way as to use the minimum number of animals and to cause the least pain, suffering, distress or lasting harm. Wherever possible and after product-specific validation, the pyrogen test is replaced by the monocyte-activation test (*2.6.30*).

F. Test for Depressor Substances

(Depressor Substances, Ph. Eur. method 2.6.11)

Carry out the test on a cat weighing not less than 2 kg and anaesthetised with chloralose or with a barbiturate that allows the maintenance of uniform blood pressure. Protect the animal from loss of body heat and maintain it so that the rectal temperature remains within physiological limits. Introduce a cannula into the trachea. Insert a cannula filled with a heparinised 9 g/L solution of sodium chloride into the common carotid artery and connect it to a device capable of giving a continuous record of the blood pressure. Insert into the femoral vein another cannula, filled with a heparinised 9 g/L solution of sodium chloride, through which can be injected the solutions of histamine and of the substance to be examined. Determine the sensitivity of the animal to histamine by injecting intravenously at regular intervals, doses of *histamine solution R* corresponding to 0.1 µg and 0.15 µg of histamine base per kilogram of body mass. Repeat the lower dose at least 3 times. Administer the second and subsequent injections not less than 1 min after the blood pressure has returned to the level it was at immediately before the previous injection. The animal is used for the test only if a readily discernible decrease in blood pressure that is constant for the lower dose is obtained and if the higher dose causes greater responses. Dissolve the substance to be examined in sufficient of a 9 g/L solution of sodium chloride or other prescribed solvent, to give the prescribed concentration. Inject intravenously per kilogram of body mass 1.0 mL of *histamine solution R*, followed by 2 successive injections of the prescribed amount of the solution to be examined and,

finally, 1.0 mL of *histamine solution R*. The second, third and fourth injections are given not less than 1 min after the blood pressure has returned to the level it was at immediately before the preceding injection. Repeat this series of injections twice and conclude the test by giving 1.5 mL of *histamine solution R* per kilogram of body mass.

If the response to 1.5 mL of *histamine solution R* per kilogram of body mass is not greater than that to 1.0 mL the test is invalid. The substance to be examined fails the test if the mean of the series of responses to the substance is greater than the mean of the responses to 1.0 mL of *histamine solution R* per kilogram of body mass or if any one dose of the substance causes a greater depressor response than the concluding dose of the histamine solution. The test animal must not be used in another test for depressor substances if the second criterion applies or if the response to the high dose of histamine given after the administration of the substance to be examined is less than the mean response to the low doses of histamine previously injected.

G. Test for Histamine

(Histamine, Ph. Eur. method 2.6.10)

Euthanise a guinea-pig weighing 250 g to 350 g that has been deprived of food for the preceding 24 h. Remove a portion of the distal small intestine 2 cm in length and empty the isolated part by rinsing carefully with solution B described below using a syringe. Attach a fine thread to each end and make a small transverse incision in the middle of the piece of intestine. Place it in an organ bath with a capacity of 10 mL to 20 mL, containing solution B maintained at a constant temperature (34 °C to 36 °C) and pass through the solution a current of a mixture of 95 parts of oxygen and 5 parts of carbon dioxide. Attach one of the threads near to the bottom of the organ bath. Attach the other thread to an isotonic myograph and record the contractions of the organ on a kymograph or other suitable means of giving a permanent record. If a lever is used, its length is such that the movements of the organ are amplified about 20 times. The tension on the intestine should be about 9.8 mN (1 g) and it should be adjusted to the sensitivity of the organ. Flush out the organ bath with solution B. Allow it to stand for 10 min. Flush 2 or 3 times more with solution B. Stimulate a series of contractions by the addition of measured volumes between 0.2 mL and 0.5 mL of a solution of *histamine dihydrochloride R* having a strength which produces reproducible submaximal responses. This dose is termed the "high dose". Flush the organ bath (preferably by overflow without emptying the bath) 3 times with solution B before each addition of histamine. The successive additions should be made at regular intervals allowing a complete relaxation between additions (about 2 min). Add equal volumes of a weaker dilution of *histamine dihydrochloride R* which produces reproducible responses approximately half as great as the "high dose". This dose is termed the "low dose". Continue the regular additions of "high" and "low" doses of histamine solution as indicated above, and alternate each addition with an equal volume of a dilution of the solution to be examined, adjusting the dilution so that the contraction of the intestine, if any, is smaller than that due to the "high dose" of histamine. Determine whether the contraction, if any, is reproducible and that the responses to the "high" and "low" doses of histamine are unchanged. Calculate the activity of the substance to be examined in terms of its equivalent in micrograms of histamine base from the dilution determined as above.

The quantity so determined does not exceed the quantity prescribed in the monograph.

If the solution to be examined does not produce a contraction, prepare a fresh solution adding a quantity of histamine corresponding to the maximum tolerated in the monograph and note whether the contractions produced by the preparation with the added histamine correspond to the amount of histamine added. If this is not the case, or if the contractions caused by the substance to be examined are not reproducible or if subsequent responses to "high" and "low" doses of histamine are diminished, the results of the tests are invalid and the test for depressor substances (*2.6.11*) must be carried out.

Solution A

Sodium chloride	160.0 g
Potassium chloride	4.0 g
Calcium chloride, anhydrous	2.0 g
Magnesium chloride, anhydrous	1.0 g
Disodium hydrogen phosphate dodecahydrate	0.10 g
Water for injections R	to 1000 mL

Solution B

Solution A	50.0 mL
Atropine sulfate	0.5 mg
Sodium hydrogen carbonate	1.0 g
Glucose monohydrate	0.5 g
Water for injections R	to 1000 mL

Solution B should be freshly prepared and used within 24 h.

H. Monocyte-Activation Test

(Ph. Eur. method 2.6.30)

1 INTRODUCTION

The monocyte-activation test (MAT) is used to detect or quantify substances that activate human monocytes or monocytic cells to release endogenous mediators such as pro-inflammatory cytokines, for example tumour necrosis factor alpha (TNFα), interleukin-1 beta (IL-1β) and interleukin-6 (IL-6). These cytokines have a role in fever pathogenesis. Consequently, the MAT will detect the presence of pyrogens in the test sample. The MAT is suitable, after a product-specific validation, as a replacement for the rabbit pyrogen test.

Pharmaceutical products that contain non-endotoxin pyrogenic or pro-inflammatory contaminants often show very steep or non-linear dose-response curves in comparison with endotoxin dose-response curves. Preparations that contain or may contain non-endotoxin contaminants have to be tested at a range of dilutions that includes minimum dilution.

The following 3 methods are described in the present chapter.

Method A. Quantitative test

Method B. Semi-quantitative test

Method C. Reference lot comparison test

In addition, further useful information on practical aspects of the tests can be found in the 'Guidance notes' section at the end of this general chapter.

The test is carried out in a manner that avoids pyrogen contamination.

2 DEFINITIONS

The maximum valid dilution (MVD) is the maximum allowable dilution of a sample at which the contaminant limit can be determined. The calculation of the MVD is based on the endotoxin reference standard. Determine the MVD using the following expression:

$$\frac{CLC \times C}{LOD}$$

CLC = contaminant limit concentration;
C = concentration of test solution;
LOD = limit of detection.

As the LOD is not always available in advance, an estimated LOD based on historical data can be used to calculate the MVD.

The acceptance criterion for a pass/fail decision is the contaminant limit concentration (CLC), which is expressed in endotoxin equivalents per milligram or millilitre or per units of biological activity of the preparation being examined.

The CLC is calculated using the following expression:

$$\frac{K}{M}$$

K = threshold pyrogenic dose per kilogram of body mass;
M = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, *M* is the maximum total dose administered in a single hour period.

Where an endotoxin limit concentration (ELC) has been specified for a product, the CLC is the same as the ELC, unless otherwise prescribed. In this case, the concentration of test solution is expressed in mg/mL if the endotoxin limit is specified by mass (IU/mg), in Units/mL if the endotoxin limit is specified by unit of biological activity (IU/Unit), in mL/mL if the endotoxin limit is specified by volume (IU/mL).

Endotoxin equivalents are values for the contaminant concentration read off the standard endotoxin dose-response curve (Method A) or estimated by comparison with responses to standard endotoxin solutions (Method B). The standard endotoxin stock solution is prepared from an endotoxin reference standard that has been calibrated against the International Standard, for example *endotoxin standard BRP*.

The LOD is determined using the endotoxin standard curve. It is the concentration of endotoxin corresponding to the cut-off value. For the purpose of the test, the LOD is expressed as endotoxin equivalents per millilitre. The cut-off value is expressed in units appropriate to the read-out (e.g. for an enzyme-linked immunosorbent assay (ELISA), use the optical density).

The cut-off value may be calculated using the following expression:

$$\bar{x} + 3s$$

$\bar{x}$ = mean of the 4 replicates for the responses to the blank (R_0);

s = standard deviation of the 4 replicates of the responses to the blank (R_0).

3 GENERAL PROCEDURE

A solution of the preparation being examined is incubated with a source of human monocytes or human monocytic cells, e.g. from human heparinised peripheral blood that is preferably not more than 4 h old, or a monocyte-containing fraction of that blood, such as human peripheral blood mononuclear cells (PBMC) isolated, e.g. by density-gradient centrifugation, or a human monocytic cell line. Human heparinised peripheral blood is usually diluted with culture medium or saline e.g. to 2-50 per cent *V/V* (final concentration). PBMC or monocytic cell lines, in culture medium and with either the donor's own plasma or AB serum, are typically used at a final cell density of 0.1-1.0 × 10^6 cells per well, tube or other receptacle. For monocytic cell lines, heat-inactivated foetal bovine serum may be substituted for AB serum. The cell culture is carried out at 37 ± 1 °C, in an atmosphere appropriate for the culture medium, e.g. 5 per cent CO_2 in humidified air. The duration of the culture is sufficient to allow accumulation of the chosen read-out. The responses of the chosen read-out, e.g. a pro-inflammatory or pyrogenic cytokine, to a solution of the preparation being examined are compared with responses to standard endotoxin or to a reference lot of the preparation being examined.

4 APPARATUS

Depyrogenate all glassware and other heat-stable apparatus in a hot-air oven using a validated process. A commonly used minimum time and temperature is 30 min at 250 °C. If employing plastic apparatus, such as microtitre plates and pipette tips for automatic pipetters, use apparatus shown to be free of detectable pyrogens and which do not interfere with the test.

5 CELL SOURCES AND QUALIFICATION

5-1 WHOLE BLOOD

Whole blood is obtained from single donors or from pooled whole blood which are qualified according to the requirements described under sections 5-3, 5-4, 5-5 and where applicable, section 6-3.

5-2 PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC)

PBMC are isolated from blood obtained from single donors or from pooled whole blood which are qualified according to the requirements described under sections 5-3, 5-4, 5-5 and where applicable, section 6-3.

5-3 QUALIFICATION OF BLOOD DONORS

Blood donors are to satisfy the following qualification criteria, together with other requirements in force that relate to consent, health and safety and ethical considerations. Blood donors are to describe themselves as being in good health, as not to be suffering from any bacterial or viral infections and to have been free from the symptoms of any such infection for a period of at least 1 week prior to the donation of blood. Blood donors are not to have taken non-steroidal anti-inflammatory drugs during the 48 h prior to donating blood and steroidal anti-inflammatory drugs during the 7 days prior to donating blood. Individuals who have been prescribed immunosuppressant or other drugs known to influence the production of the chosen readout are not to serve as blood donors. Blood donations are to be tested for infection markers according to national requirements for transfusion medicine.

5-4 QUALIFICATION OF CELLS POOLED FROM A NUMBER OF DONORS

Pools (of whole blood or blood fractions, e.g. PBMC), must consist of donations from a minimum of 4 individual donors

but preferably 8 or more donors, where practicable, taking from each donation an approximately equal volume of blood, or cells from an approximately equal volume of blood. For the qualification of pooled cells proceed as follows: within 4 h of collection of blood, generate dose-response curves from the pool using standard endotoxin with at least 4 geometrically diluted endotoxin concentrations, e.g. in the range of 0.01 IU/mL to 4 IU/mL. The dose-response curves are to meet the 2 criteria for the endotoxin standard curve described under section 6-1. If the pool is to be used for the detection of non-endotoxin contaminants, pools are to be qualified as described in section 6-3. Where cells are pooled, the averaging effect is to be considered when setting the pass/fail specification for a given product.

5-5 QUALIFICATION OF CRYO-PRESERVED CELLS

The cell source intended for use in a MAT, e.g. human whole blood, blood fractions, such as PBMC or monocytic cell lines, may be cryo-preserved. Pools of cryo-preserved cells are obtained by pooling before freezing, or by pooling single cryo-preserved donations immediately after thawing. Qualification of cryo-preserved blood or cells is performed immediately after thawing (and pooling if necessary). Dose-response curves for the cryo-preserved blood or cells are to comply with the 2 criteria for the endotoxin standard curve described under section 6-1. Qualification of the cryo-preserved blood or cells is to be performed according to section 6-3 if the intended use is for the detection of non-endotoxin contaminants.

5-6 MONOCYTIC CONTINUOUS CELL LINES

Monocytic cell lines are appropriate for the detection of bacterial endotoxins, but have limited use for the detection of non-endotoxin pyrogens.

A human monocytic cell line is cultured in order to ensure a sufficient supply for the MAT. To optimise the method, clones derived from the cell line can be used.

Cells must be maintained under aseptic conditions and regularly tested for the presence of mycoplasma contamination. Additionally, cells must be regularly checked for identity (e.g. doubling time, morphology, and function) and stability. The functional stability of a cell line is assessed by monitoring its performance in relation to the number of passages during routine testing. Criteria for functional stability are to be established and may include growth criteria, maximum signal obtained in the test, background noise and receptor expression. The receptor expression may be tested with specific ligands e.g. lipopolysaccharide (LPS) for toll-like receptor 4 (TLR4), lipoteichoic acid (LTA) for toll-like receptor 2 (TLR2), synthetic bacterial lipoprotein for TLR2-TLR1, synthetic bacterial lipoprotein for TLR2-TLR6 or flagellin.

The dose-response curves are to meet the 2 criteria for the endotoxin standard curve described under section 6-1. If the cells are to be used for the detection of non-endotoxin contaminants, they are to be qualified as described in section 6-3.

6 PREPARATORY TESTING

To ensure both the precision and validity of the test, preparatory tests are conducted, to assure that the criteria for the endotoxin standard curve are satisfied, that the solution does not interfere with the test, that the test detects endotoxins and non-endotoxins contaminants and that the solution does not interfere in the detection system.

A test for interfering factors is required when any changes are made to the experimental conditions that are likely to influence the result of the test.

6-1 ASSURANCE OF CRITERIA FOR THE ENDOTOXIN STANDARD CURVE

Using the standard endotoxin solution, prepare at least 4 endotoxin concentrations to generate the standard curve. Perform the test using at least 4 replicates of each concentration of standard endotoxin.

The basal release of the chosen read-out (blank) in the absence of added standard endotoxin is optimised to be as low as possible (e.g. an optical density below 0.1 when using an ELISA).

There are 2 acceptance criteria for the standard curve:

— the regression of responses (appropriately transformed if necessary) on $\log_{10}$ dose shall be statistically significant ($p < 0.01$);

— the regression of responses on $\log_{10}$ dose must not deviate significantly from linearity ($p > 0.05$) (see chapter *5.3. Statistical analysis*).

6-2 TEST FOR INTERFERING FACTORS

To assure the validity of the test, preparatory tests are conducted to ensure that the preparation being examined does not interfere with the test. Using an appropriate diluent, dilute the preparation being examined in geometric steps, with all dilutions not exceeding the MVD. Make the same dilutions of the preparation being examined and add endotoxin at a justified concentration. Alternatively, use a diluent containing added endotoxin at a justified concentration. In both cases, this concentration is usually equal to or near the estimated middle of the endotoxin standard curve (Method A) or twice the estimated LOD (Method B). Test these dilution series in parallel in the same experiment. Use the endotoxin standard curve to calculate the concentration of endotoxin-equivalents in each solution. Calculate the mean recovery of the added endotoxin by subtracting the mean concentration of endotoxin equivalents in the solution (if any) from that in the solution containing the added endotoxin. The test solution is considered free of interfering factors if, under the conditions of the test, the measured endotoxin equivalents in the test solution to which endotoxin is added is within 50-200 per cent of the added concentration, after subtraction of any endotoxin equivalents detected in the solution without added endotoxin. When this criterion is not met, Method C is to be preferred over Methods A and B.

In Method C, the dilutions of the test and reference lots depend on the type of analysis used to make the comparison between the two. The type of analysis is to be justified and validated for each product, and is to include assay validity criteria. In an example, a solution of the preparation being examined is tested at 3 dilutions: the highest concentration (lowest dilution) that stimulates the greatest release of the chosen read-out and the 2-fold dilutions immediately below and above the chosen dilution. Since the concentration that stimulates the greatest release of the chosen read-out may be donor-dependent as well as batch-dependent, the product-specific validation is to be performed in at least 3 independent tests, each using cells from different donors. The highest concentration (lowest dilution) that stimulates the greatest release of the chosen read-out in the majority of donors, and the 2-fold dilutions immediately below and above that dilution are deemed to be validated for further testing. If undiluted test solution stimulates the greatest release of the chosen read-out, subsequent testing is to be performed using undiluted test solution and also test solution diluted in the ratios 1:2 and 1:4 before its addition to the monocytic cells. The dilution factors for these 3 solutions are designated f_1, f_2 and f_3.

If the pyrogen content of the product is inherently high, it may be more appropriate to carry out, for example, a parallel-line analysis on the dose-response curves for the test and reference lots. In this situation, solutions of the preparations are tested at 3 or more geometric dilutions which cover the range of the dose-response curve used for the validated analysis (see chapter *5.3. Statistical analysis*).

6-3 METHOD VALIDATION FOR NON-ENDOTOXIN MONOCYTE-ACTIVATING CONTAMINANTS

The preparatory testing is also to show that the chosen test system detects, in addition to bacterial endotoxins, non-endotoxin pro-inflammatory or pyrogenic contaminants. The suitability of the method for the particular product has to be verified. This can be achieved using historic batches found to be contaminated with non-endotoxin contaminants that caused positive responses in the rabbit pyrogens test or adverse drug reactions in man. Where such batches are not available, the preparatory testing is to include validation of the test system using at least 2 non-endotoxin ligands for toll-like receptors, e.g. peptidoglycans, lipoteichoic acids, synthetic bacterial lipoproteins, flagellin and crude bacterial whole cell extract, at least 1 of which is to be spiked into the preparation being examined. The choice of non-endotoxin pyrogens used should reflect the most likely contaminant(s) of the preparation being examined.

6-4 INTERFERENCE IN THE DETECTION SYSTEM

Once the optimum dilution of the solution of the preparation being examined for further testing has been identified, this dilution is tested for interference in the detection system (e.g. ELISA) for the chosen read-out. The agreement between a dilution series of the standard for the chosen read-out, in the presence and absence of the preparation being examined, is to be within, for example ± 20 per cent of the optical density.

7 METHODS

7-1 METHOD A: QUANTITATIVE TEST

Method A involves a comparison of the preparation being examined with a standard endotoxin dose-response curve. The contaminant concentration of the preparation being examined is to be less than the CLC to pass the test.

7-1-1 Test procedure

Using the validated test method, prepare the solutions shown in Table 2.6.30.-1 and culture 4 replicates of each solution with the qualified cells.

Solution A = solution of the preparation being examined at the dilution, here designated *f*, at which the test for interfering factors was carried out, i.e. the highest concentration (lowest dilution) for which the endotoxin recovery is within 50-200 per cent.

Solution B = 2-fold dilution of solution A, not exceeding the MVD.

Solution C = 2-fold dilution of solution B, not exceeding the MVD.

Solution AS = solution A spiked with standard endotoxin at a concentration equal to the middle dose from the endotoxin standard curve (R_3).

Solution BS = solution B spiked with standard endotoxin at a concentration equal to the middle dose from the endotoxin standard curve (R_3).

Solution CS = solution C spiked with standard endotoxin at a concentration equal to the middle dose from the endotoxin standard curve (R_3).

Solution R_0 = negative control.

Table 2.6.30.-1

Solution	Solution	Added endotoxin (IU/mL)	Number of replicates
A	Test solution/*f*	None	4
B	Test solution/2 × *f*	None	4
C	Test solution/4 × *f*	None	4
AS	Test solution/*f*	Middle dose from endotoxin standard curve (R_3)	4
BS	Test solution/2 × *f*	Middle dose from endotoxin standard curve (R_3)	4
CS	Test solution/4 × *f*	Middle dose from endotoxin standard curve (R_3)	4
R_0	Pyrogen-free saline or test diluent	None (negative control)	4
R_1-R_4	Pyrogen-free saline or test diluent	4 concentrations of standard endotoxin	4 of each concentration

Solutions R_1-R_4 = solutions of standard endotoxin at the concentrations used in the test for interfering factors.

7-1-2 Calculation and interpretation

All data to be included in the data analysis are to relate to cells for which the 2 criteria for the endotoxin standard curve are satisfied. For each different cell source, e.g. individual donation, donor pool, or cell line, use the endotoxin standard curve R_1-R_4 to calculate the concentration of endotoxin equivalents in each of the replicates of solutions A, B and C and solutions AS, BS and CS. The recovery of endotoxin equivalents calculated from the endotoxin equivalents concentration found in solutions AS, BS and CS after subtracting the endotoxin equivalents concentration found in solutions A, B and C is within the range of 50-200 per cent. Dilutions not fulfilling the spike recovery argument are not valid and are therefore excluded from further evaluation. The preparation being examined complies with the requirements of the test for a given cell source if the mean concentrations of endotoxin equivalents measured in the replicates of solutions A, B and C, after correction for dilution and concentration, are all less than the CLC specified for the preparation being examined. One valid dilution is the minimum required for a valid test.

7-1-3 Pass/fail criteria of the preparation

When cells from individual donors are used, the preparation being examined is required to comply with the test with the cells from each of 4 different donors. If the preparation being examined passes the test with cells from 3 of the 4 donors, the test is continued with cells from a further 4 donors, none of whom provided cells for the 1st test, and the preparation being examined is required to pass the test with cells from 7 of the 8 different donors (i.e. a maximum of 1 positive reaction in 8 donors is allowed). When the source of monocytes consists of cells pooled from a number of individual donors, the preparation being examined is required to pass the test with 1 pool of cells. Where a human monocytic cell line is used for the test, the preparation being examined is required to pass the test with 1 qualified passage of cells.

7-2 METHOD B. SEMI-QUANTITATIVE TEST

Method B involves a comparison of the preparation being examined with standard endotoxin. The contaminant concentration of the preparation being examined is to be less than the CLC to pass the test. Solution A must be chosen for the pass decision, unless otherwise justified and authorised.

7-2-1 Test procedure

Using the validated test method, prepare the solutions shown in Table 2.6.30.-2 and culture 4 replicates of each solution with the qualified cells.

Table 2.6.30.-2

Solution	Solution	Added endotoxin (IU/mL)	Number of replicates
A	Test solution/*f*	None	4
B	Test solution/f_1	None	4
C	Test solution/f_2	None	4
AS	Test solution/*f*	Standard endotoxin at 2 × estimated LOD for the test system	4
BS	Test solution/f_1	Standard endotoxin at 2 × estimated LOD for the test system	4
CS	Test solution/f_2	Standard endotoxin at 2 × estimated LOD for the test system	4
R_0	Pyrogen-free saline or test diluent	None (negative control)	4
R_1	Pyrogen-free saline or test diluent	Standard endotoxin at 0.5 × estimated LOD for the test system	4
R_2	Pyrogen-free saline or test diluent	Standard endotoxin at 1 × estimated LOD for the test system	4
R_3	Pyrogen-free saline or test diluent	Standard endotoxin at 2 × estimated LOD for the test system	4
R_4	Pyrogen-free saline or test diluent	Standard endotoxin at 4 × estimated LOD for the test system	4

Solution A = solution of the preparation being examined at the dilution, here designated *f*, at which the test for interfering factors was completed.

Solution B = solution of the preparation being examined at a dilution, here designated f_1, not exceeding the MVD, chosen after a review of data from the product-specific validation, e.g. 1:2 × MVD (i.e. 2 times less diluted than the MVD).

Solution C = solution of the preparation being examined at a dilution, here designated f_2, not exceeding the MVD, chosen after a review of data from the product-specific validation, e.g. MVD.

Solution AS = solution A spiked with standard endotoxin at 2 × estimated LOD for the test system (as determined in preparatory testing).

Solution BS = solution B spiked with standard endotoxin at 2 × estimated LOD for the test system.

Solution CS = solution C spiked with standard endotoxin at 2 × estimated LOD for the test system.

Solution R_0 = negative control.

Solution R_1 = standard endotoxin at 0.5 × estimated LOD for the test system.

Solution R_2 = standard endotoxin at 1 × estimated LOD for the test system.

Solution R_3 = standard endotoxin at 2 × estimated LOD for the test system.

Solution R_4 = standard endotoxin at 4 × estimated LOD for the test system.

7-2-2 Calculation and interpretation

All data to be included in the data analysis are to relate to cells for which mean responses to solutions R_0-R_4 increase progressively. The mean response to R_0 may be equal to the mean response to R_1. For each different cell source, the mean response to solution R_2 is to be greater than a positive cut-off value. Data below this cut-off value are considered negative. If the mean response to R_1 or R_2 exceeds the cut-off value, the response to the solution chosen for the pass/fail decision must be negative (= pass). For each negative solution of the preparation being examined (A, B and C), the mean response to the corresponding spiked solution (AS, BS or CS respectively) is compared with the mean response to R_3 to determine the percentage spike recovery.

The contaminant concentration of the preparation being examined is less than the CLC for a given cell source if the solution of the preparation being examined designated for the pass/fail-decision and the dilutions below all give negative results and the endotoxin spike recovery is within the range of 50-200 per cent.

7-2-3 Pass/fail criteria of the preparation

The criteria are the same as for method A (see 7-1-3).

7-3 METHOD C: REFERENCE LOT COMPARISON TEST

Method C involves a comparison of the preparation being examined with a validated reference lot of that preparation. The type of analysis selected to compare the two is to be justified and validated for each product and is to include assay validity criteria. The reference lot is also selected according to criteria that have been justified and authorised. The test is intended to be performed in cases where a preparation being examined shows marked interference but cannot be diluted within the MVD to overcome the interference or because it contains or is believed to contain non-endotoxin contaminants. Responses to non-endotoxin contaminants may dilute out more rapidly than responses to endotoxin, which makes it necessary to perform the test at a range of dilutions that include minimum dilution. The test procedure is described below and includes an example of a type of analysis used for the comparison of a test lot and reference lot.

7-3-1 Test procedure

Using the validated test method, prepare the solutions shown in Table 2.6.30.-3 and culture 4 replicates of each solution with the qualified cells.

Table 2.6.30.-3

Solution	Solution/dilution factor	Number of replicates
A	Solution of reference lot/f_1	4
B	Solution of reference lot/f_2	4
C	Solution of reference lot/f_3	4
D	Solution of preparation being examined/f_1	4
E	Solution of preparation being examined/f_2	4
F	Solution of preparation being examined/f_3	4
G	Positive control (standard endotoxin)	4
R_0	Diluent (negative control)	4

Solutions A, B and C are solutions of the reference lot diluted by the dilution factors, f_1, f_2 and f_3, determined in the test for interfering factors.

Solutions D, E and F are solutions of the preparation being examined diluted by the dilution factors, f_1, f_2 and f_3, determined for the reference lot in the test for interfering factors.

Solution G is the positive test control for the viability of the cells and is a standard endotoxin concentration that gives a clear positive response.

Solution R_0 is the diluent used to dilute the preparation being examined and serves as the test blank.

7-3-2 Calculation and interpretation

All data to be included in the data analysis are to relate to cells for which solution G and at least one of solutions A, B and C give a response that is greater than the basal release of the read-out (Solution R_0). For each different cell source, e.g. individual donation, donor pool, or cell line, use the standard curve for the read-out (a calibration curve in duplicate with a blank and at least 4 geometrically diluted concentrations of the standard for the chosen read-out) and calculate the mean responses of the replicates of solutions A-F. Sum the mean responses to solutions A, B and C and sum the mean responses to solutions D, E and F. Divide the sum of the mean responses to solutions D, E and F by the sum of the mean responses to solutions A, B and C.
The preparation being examined complies with the test for a given cell source if the resulting value complies with a defined acceptance criterion not exceeding a justified value, e.g. 2.5.

7-3-3 Pass/fail criteria of the preparation

The criteria are the same as for method A (see 7-1-3).

To quantify more closely the level of contamination, Methods A, B and C may be performed using other dilutions of the solution of the preparation being examined not exceeding the MVD.

The following section is published for information only.

GUIDANCE NOTES

1 INTRODUCTION

The monocyte-activation test (MAT) is primarily intended to be used as a replacement for the rabbit pyrogen test.
The MAT detects pyrogenic and pro-inflammatory contaminants, including endotoxins from gram-negative bacteria and 'non-endotoxin' contaminants, including pathogen-associated molecular patterns (PAMPs), derived from gram-positive and gram-negative bacteria, viruses and fungi, and product-related and process-related biological or chemical entities.

Since non-endotoxin contaminants are a physico-chemically diverse class of molecules, and usually the nature of the contaminant in a preparation being examined is unknown, the level of contamination is expressed either in endotoxin-equivalent units, derived by comparison with responses to standard endotoxin, or by comparison with a reference lot of the preparation being examined.

In the MAT, responses to standard endotoxin usually dilute out over approximatively 1 $\log_{10}$ and responses to products contaminated with non-endotoxin contaminants (alone or in combination with endotoxins) often show very steep dose-response curves, usually over only 1 or 2 dilution steps when tested for their capability to stimulate monocytes. Frequently, the largest response to such contaminated products is obtained with undiluted solutions of preparations being examined or small dilutions of the preparations being examined. For this reason test solutions of preparations being examined that contain or may contain non-endotoxin contaminants have to be tested at a range of dilutions that includes minimum dilution.

2 METHODS

2-1 INFORMATION REGARDING THE CHOICE OF METHODS

Methods A, B and C, are not normally applied where a preparation being examined has the intrinsic activity of stimulating the release of the chosen read-out or where the preparation being examined is contaminated with the chosen read-out. In both cases, this fact is to be addressed by modifying and validating the chosen method accordingly. The product-specific validation of the chosen method would be expected to identify the frequency of non-responders to a particular product/contaminant(s) combination and to identify steps to address this, e.g. screening of donors, increasing the number of donors per test, and setting pass/fail criteria of appropriate stringency to maximise the likelihood of detecting contaminated batches. Method A is not appropriate if the results of different dilutions (endotoxin equivalents per millilitre) show that the dose response curve is not parallel to the standard endotoxin curve. Method B is a semi-quantitative test that can be applied when responses to dilutions of a preparation being examined are not parallel to responses to dilutions of standard endotoxin.

Method C, the reference lot comparison test, was developed to address extreme donor variability in responses to certain product/contaminant(s) combinations. In this regard, it should be noted that, while monocytes from most donors respond in a broadly similar manner to bacterial endotoxin, responses of monocytes from different donors to non-endotoxin contaminants can differ markedly, so that it is possible to identify non-responders along with low and high responders to certain product/contaminant(s) combinations.

2-2 CALCULATION OF CONTAMINANT LIMIT CONCENTRATION

The acceptance criterion for a pass/fail decision is the contaminant limit concentration (CLC), which is expressed in endotoxin equivalents per milligram or millilitre or in units of biological activity of the preparation being examined. Where an endotoxin limit concentration (ELC) has been specified for a product, the CLC is the same as the ELC, unless otherwise prescribed. The CLC is expressed in terms of endotoxin equivalents. The CLC is calculated using the following expression:

$$\frac{K}{M}$$

K = threshold pyrogenic dose per kilogram of body mass;
M = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, M is the maximum total dose administered in a single hour period.

The CLC depends on the product and its route of administration and is stated in some monographs.

Values for K are suggested in Table 2.6.30.-4.

Table 2.6.30.-4

Route of administration	K
Intravenous	5.0 IU of endotoxin per kilogram of body mass
Intravenous, for radiopharmaceuticals	2.5 IU of endotoxin per kilogram of body mass
Intrathecal	0.2 IU of endotoxin per kilogram of body mass
Parenteral formulations administered per square metre of body surface	100 IU/m^2

2-3 INFORMATION REGARDING CRYO-PROTECTANTS

The influence of cryo-protectants, e.g. dimethyl sulfoxide (DMSO), and their residues in thawed cells, is to be considered: DMSO is toxic to cells in culture and, even when cells have been washed thoroughly, cryo-preservation may have altered cell properties, e.g. cell membrane permeability.

2-4 INTERFERENCE TESTING

Where practicable, interference testing is performed on at least 3 different lots of the preparation being examined. Preparations being examined that show marked batch-to-batch variation, that effectively renders each batch unique for the purposes of interference testing, are to be subjected to interference testing within each individual test, i.e. concomitant validation.

Interference testing is preferably performed on batches of the preparation being examined that are free of endotoxins and other pyrogenic/pro-inflammatory contaminants and, where this is not practicable, none of the batches are to be heavily contaminated. If only 1 batch is available the validation has to be performed on that batch in 3 independent tests. Precision parameters for reproducibility, e.g. ± 50 per cent, are to be fulfilled.

2-5 CROSS-VALIDATION

General chapter *5.1.10. Guidelines for using the test for bacterial endotoxins*, states that an MAT should be performed on products where the presence of non-endotoxin pyrogenic substances cannot be ruled out. It is therefore recommended to perform cross-validation experiments with the MAT together with the validation experiments for the test for bacterial endotoxins (BET) using the same 3 batches. Cross-validation should be repeated on 3 batches if important process parameters have changed, as potential contamination by non-endotoxin pyrogens cannot be ruled out.

The rabbit pyrogen test (see general chapter *2.6.8. Pyrogens*) must only be performed for cross validation if none of the MAT methods (A, B or C) can be validated for a certain product.

3 REPLACEMENT OF THE RABBIT PYROGEN TEST BY THE MONOCYTE ACTIVATION TEST

As noted above, MAT is primarily intended to be used as a replacement for the rabbit pyrogen test. Monographs on pharmaceutical products intended for parenteral administration that may contain pyrogenic contaminants require either a test for bacterial endotoxins or a monocyte activation test.

As a general policy:

— in any individual monograph, when a test is required, only 1 test is included, either that for bacterial endotoxins or the MAT. Before including the MAT in a monograph, evidence is required that 1 of the 3 methods described in the MAT chapter can be applied satisfactorily to the product in question;
— the necessary information is sought from manufacturers. Companies are invited to provide any validation data that they have concerning the applicability of the MAT to the substances and formulations of interest. Such data include details of sample preparation and of any procedures necessary to eliminate interfering factors. In addition, any available parallel data for rabbit pyrogen testing that would contribute to an assurance that the replacement of a rabbit pyrogen test by the MAT is appropriate, is to be provided.

4 VALIDATION OF ALTERNATIVE METHODS

Replacement of a rabbit pyrogen test, or replacement of a method for detecting pro-inflammatory/pyrogenic contaminants by another method, is to be regarded as the use of an alternative method in the replacement of a pharmacopoeial test, as described in the General Notices.

The following procedures are suggested for validating a method for the MAT other than the one indicated in the monograph:

— the procedure and the materials and reagents used in the method should be validated as described for the test concerned;
— the presence of interfering factors (and, if needed, the procedure for removing them) should be tested on samples of at least 3 production batches.

MAT should be applied to all new products intended for parenteral administration that have to be tested for the presence of non-endotoxin pyrogens according to the requirements of the European Pharmacopoeia.

I. Assay of Pancreatin

The free protease, lipase and amylase activities of pancreatin are determined by the following methods.

Standard preparation and units

The Standard Preparation is the appropriate FIP Standard which has been adopted as an official preparation by the European Pharmacopoeia Commission and is available as

pancreas powder (protease) EPBRP or *pancreas powder (amylase and lipase) EPBRP* as appropriate.

The Unit of protease activity is contained in that amount of the Standard Preparation that, under the conditions of the assay, hydrolyses casein at an initial rate such that there is liberated per minute an amount of peptides not precipitated by trichloroacetic acid that gives the same absorbance at 275 nm as one micromole of tyrosine. The Unit of lipase activity is contained in that amount of the Standard Preparation that, under the conditions of the assay, liberates one micro-equivalent of acid per minute at pH 9.0 and 37°. The Unit of amylase activity is contained in that amount of the standard preparation that, under the conditions of the assay, decomposes starch at an initial rate such that one micro-equivalent of glycosidic linkage is hydrolysed per minute.

1. Free protease activity

Method

Solution of the standard preparation Triturate for 5 minutes a quantity of the Standard Preparation containing approximately 100 Units of protease activity with 25 mL of *calcium chloride solution* cooled to 5°. Dilute to 100 mL with the cooled *calcium chloride solution* and then dilute a sufficient quantity of the resulting suspension to 100 mL *with borate buffer pH 7.5*, cooled to 5°, so that 1 mL of the final solution contains 0.065 Units of protease activity.

Solution of the substance being examined Triturate for 5 minutes a quantity of the substance being examined containing approximately 100 Units of protease activity with 25 mL of *calcium chloride solution* cooled to 5°. Dilute to 100 mL with the cooled *calcium chloride solution* and then dilute a sufficient quantity of the resulting suspension to 100 mL with *borate buffer pH 7.5*, cooled to 5°, so that the estimated free protease activity corresponds approximately to the activity of the solution of the Standard Preparation.

Label 16 test tubes with the following identification in duplicate; S_1, S_2, S_3, S_1B, S_2B, S_3B, U and UB. To tubes S_1 and S_1B add 2.0 mL and to tubes S_2, S_2B, U and UB, 1.0 mL of *borate buffer pH 7.5*. Then to tubes S_1 and S_1B add 1.0 mL, to tubes S_2 and S_2B, 2.0 mL and to tubes S_3 and S_3B, 3.0 mL of the solution of the Standard Preparation. Add 2.0 mL of the solution of the substance being examined to tubes U and UB. To each of the control tubes (S_1B, S_2B, S_3B and UB) add 5.0 mL of a 5% w/v solution of *trichloroacetic acid* and mix. Place a stirring rod in each tube and warm to, and maintain at, 35° in a water bath. Add 5.0 mL of *concentrated casein substrate* to each of the control tubes and mix.

At accurately timed intervals add 5.0 mL of *concentrated casein substrate*, previously warmed to 35°, to tubes S_1, S_2, S_3 and U and mix immediately. After exactly 30 minutes, in the same order, stop the reaction in tubes S_1, S_2, S_3 and U by adding 5.0 mL of a 5% w/v solution of *trichloroacetic acid* and mix thoroughly. Remove all the test tubes from the water bath and allow to stand at room temperature for 20 minutes. Filter the contents of the tubes through suitable filter paper[1], collect the filtrates and refilter through the same paper. The filtrates must be free from haze.

Measure the *absorbances* of the filtrates at the maximum at 275 nm, Appendix II B, using in the reference cell a mixture of 6.0 mL of *borate buffer pH 7.5* and 5.0 mL of the 5% w/v solution of *trichloroacetic acid* that has been filtered in the same way. Correct the mean absorbances of the filtrates from tubes S_1, S_2 and S_3 by subtracting the mean absorbances of the filtrates from the corresponding control tubes S_1B, S_2B and S_3B.

Prepare a reference curve by plotting the mean corrected absorbances against the potency of the dilution of the solution of the Standard Preparation used. Calculate the corrected mean absorbance of the substance being examined by subtracting the mean absorbance of the filtrates from tubes UB from that of the filtrates from tubes U. Using the corrected mean absorbance, determine the potency of the solution of the substance being examined from the reference curve and calculate the free protease activity per mg of the substance being examined by taking into account the dilution factors.

The test is not valid unless the corrected absorbances are between 0.15 and 0.60.

2. Lipase activity

Apparatus

Use a reaction vessel of about 50 mL capacity fitted with a device that will maintain a temperature of 36.5° to 37.5°, a magnetic stirrer and a lid with holes for the insertion of electrodes, the tip of a burette, a tube for the admission of nitrogen and the introduction of reagents. An automatic or manual titration apparatus may be used. In the latter case, the burette is graduated in 5-µL divisions and the pH meter is provided with a wide reading scale and glass and calomel electrodes. After each test the reaction vessel is evacuated by suction and washed several times with water, the washings being removed each time by suction.

Method

Carry out the assay under nitrogen. In a small mortar cooled to 0° to 4° triturate carefully an amount of the substance being examined containing approximately 2500 Units of lipase activity with 1 mL of cooled *lipase solvent* until a very fine suspension is obtained (about 10 minutes). Dilute with cooled *lipase solvent*, transfer quantitatively to a graduated flask and dilute to 100.0 mL with the cooled solvent; use immediately.

Transfer 29.5 mL of *olive oil substrate emulsion* to the assembled reaction vessel equilibrated at 36.5° to 37.5° and adjust the pH to 9.2 with 0.1M *sodium hydroxide*. Add about 0.5 mL of the suspension of the preparation being examined and record the time at which the pH reaches 9.0. Add continuously from a micrometer syringe sufficient *0.1M sodium hydroxide VS* to maintain the pH at 9.0. Record the volume of *0.1M sodium hydroxide VS* consumed at 1-minute intervals for 5 minutes. Discounting the first reading, calculate the mean rate of alkali consumption *U*. If necessary, dilute with sufficient *lipase solvent* to produce an average alkali consumption of 0.08 to 0.16 mL of *0.1M sodium hydroxide VS* per minute. Repeat the procedure using the Standard Preparation in place of the substance being examined and calculate the mean rate of alkali consumption, *S*. Calculate the potency (P_L) of the substance being examined in Units per mg from the expression:

$$P_L = \frac{U}{S} \times \frac{w_S}{w} \times R$$

[1] *A suitable filter paper complies with the following test. Filter 5 mL of a 5% w/v solution of trichloroacetic acid through a sample of the paper and measure the absorbance of the filtrate at 275 nm, Appendix II B, using the unfiltered 5% w/v solution of trichloroacetic acid in the reference cell. The absorbance is not more than 0.04.*

Where U = the mean volume in mL of *0.1M sodium hydroxide VS* used per minute in the titration of the substance being examined,
S = the mean volume in mL of *0.1M sodium hydroxide VS* used per minute in the titration of the Standard Preparation,
w = weight in mg of the substance being examined,
w_s = weight in mg of the Standard Preparation,
R = potency of the Standard Preparation in Units per mg.

Calculate the potency of the preparation being examined using the average of three separate titrations for both the substance being examined and the Standard Preparation.

3. Amylase activity

Method

Triturate an amount of the preparation being examined containing approximately 1500 Units of amylase activity with 60 mL of *0.2M mixed phosphate buffer pH 6.8* for 15 minutes and add sufficient *0.2M mixed phosphate buffer pH 6.8* to produce 100 mL. To a stoppered tube (200 mm × 22 mm) add 25.0 mL of *starch substrate*, 10.0 mL of *0.2M mixed phosphate buffer pH 6.8* and 1.0 mL of *0.2M sodium chloride*. Stopper the tube, mix the contents and place in a water bath at 24.9° to 25.1°. When the temperature of the mixture has reached 25° add 1.0 mL of the solution of the substance being examined and record the time of addition.
Mix thoroughly and replace in the water bath. After exactly 10 minutes add 2 mL of 1M *hydrochloric acid* to stop the reaction. Transfer the contents of the tube to a stoppered 300 mL flask. While shaking continuously add 10.0 mL of *0.05M iodine VS* followed immediately by 45 mL of *0.1M sodium hydroxide*. Allow to stand in the dark at a temperature of 15° to 25° for 15 minutes. Add 4 mL of a mixture of 1 volume of *sulfuric acid* and 4 volumes of *water* and titrate with *0.1M sodium thiosulfate VS*. Repeat the procedure but add the 2 mL of 1M *hydrochloric acid* before the addition of the solution of the substance being examined. Prepare a solution of the Standard Preparation in the same manner as described for the solution of the substance being examined and repeat the procedure beginning at the words 'To a stoppered tube ...' but using 1.0 mL of this solution in place of the solution of the substance being examined.

Calculate the potency (P_A) of the preparation being examined in Units per mg from the expression:

$$P_A = \frac{(B - A)w_s}{(B_s - A_s)w} \times Q$$

Where A = volume in mL of *0.1M sodium thiosulfate VS* used in the titration of the substance being examined,
A_s = volume in mL of *0.1M sodium thiosulfate VS* used in the titration of the Standard Preparation
B = volume in mL of *0.1M sodium thiosulfate VS* used in the titration of the substance being examined inactivated by the addition of 1M hydrochloric acid,
B_s = volume in mL of *0.1M sodium thiosulfate VS* used in the titration of the Standard Preparation inactivated by the addition of 1M hydrochloric acid,
Q = potency of the Standard Preparation in Units per mg
w = total weight in mg of the substance being examined in the solution prepared for assay,
w_s = total weight in mg of the Standard Preparation in the solution prepared for assay.

J. Blood and Related Products

Coagulants

A1. Assay of Human Coagulation Factor II

(Ph. Eur. method 2.7.18)

Human coagulation factor II is assayed following specific activation to form factor IIa. Factor IIa is estimated by comparing its activity in cleaving a specific chromogenic peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor II activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human blood coagulation factor II. The equivalence in International Units of the International Standard is stated by the World Health Organization.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor II, followed by enzymatic cleavage of a chromogenic factor IIa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor IIa activity and the cleavage of the chromogenic substrate.

REAGENTS

Viper venom specific factor II activator (ecarin). A protein derived from the venom of the saw-scaled viper (*Echis carinatus*) which specifically activates factor II. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

Factor IIa chromogenic substrate Specific chromogenic substrate for factor IIa such as: *H*-D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide dihydrochloride, 4-toluenesulfonyl-glycyl-prolyl-L-arginine-4-nitroanilide, *H*-D-cyclohexylglycyl-α-aminobutyryl-L-arginine-4-nitroanilide, D-cyclohexylglycyl-L-alanyl-L-arginine-4-nitroanilide diacetate. Reconstitute according to the manufacturer's instructions.

Dilution buffer Solution containing 6.06 g/L of *tris (hydroxymethyl)aminomethane R*, 17.53 g/L of *sodium chloride R* and 1 g/L of *bovine albumin R* or *human albumin R*. Adjust to pH 8.4 if necessary, using *hydrochloric acid R*.

METHOD

Test solution Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Reference solution Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 25 µL of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 125 µL of dilution buffer, then 25 µL of ecarin and incubate for exactly 2 min. To each well add 25 µL of factor IIa chromogenic substrate.

Read the rate of change of absorbance (*2.2.25*) at 405 nm continuously over a period of 3 min and obtain the mean

rate of change of absorbance (ΔA/min). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate ΔA/min as the slope of the line. From the ΔA/min values of each individual dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (*5.3*).

A2. Assay of Human Coagulation Factor VII

(Ph. Eur. method 2.7.10)

Human coagulation factor VII is assayed by its biological activity as a factor VIIa-tissue factor complex in the activation of factor X in the presence of calcium ions and phospholipids. The potency of a factor VII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

The International Unit is the factor VII activity of a stated amount of the International Standard, which consists of freeze-dried plasma. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Human coagulation factor VII concentrate BRP is calibrated in International Units by comparison with the International Standard.

The chromogenic assay method consists of 2 consecutive steps: the factor VII-dependent activation of factor X reagent mixture containing tissue factor, phospholipids and calcium ions, followed by enzymatic cleavage of a chromogenic factor Xa substrate into a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VII concentration. The assay is summarised in the following scheme.

Step 1

a) factor VII $\xrightarrow{\text{tissue factor, } Ca^{2+}}$ factor VIIa

b) factor X $\xrightarrow[\text{tissue factor/phospholipid}]{\text{factor VIIa, } Ca^{2+}}$ factor Xa

Step 2

chromogenic substrate $\xrightarrow{\text{factor Xa}}$ peptide + chromophore

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification.

REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X and thromboplastin tissue factor/phospholipid as factor VII activator. These proteins are partly purified and do not contain impurities that interfere with the activation of factor VII or factor X. Factor X is present in amounts giving a final concentration during the first step of the assay of 10-350 nmol/L, preferably 14-70 nmol/L. Thromboplastin from natural sources (bovine or rabbit brain) or synthetic preparations may be used as the tissue factor/phospholipid component. Thromboplastin suitable for use in prothrombin time determination is diluted 1:5 to 1:50 in buffer such that the final concentration of Ca^{2+} is 15-25 mmol/L. The final factor Xa generation is performed in a solution containing human or bovine albumin at a concentration such that adsorption losses do not occur and which is appropriately buffered at pH 7.3-8.0. In the final incubation mixture, factor VII must be the only rate-limiting component and each reagent component must lack the ability to generate factor Xa on its own.

The second step comprises the quantification of the formed factor Xa employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a short peptide of between three and five amino acids, bound to a chromophore group. On cleavage of this group from the peptide substrate, its absorption maximum shifts to a wavelength allowing its spectrophotometric quantification. The substrate is usually dissolved in *water R* and used at a final concentration of 0.2-2 mmol/L. The substrate may also contain appropriate inhibitors to stop further factor Xa generation (addition of edetate).

ASSAY PROCEDURE

Reconstitute the entire contents of one ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of *water R*; use within 1 h. Add sufficient prediluent to the reconstituted preparations to produce solutions containing between 0.5 IU and 2.0 IU of factor VII per millilitre.

Prepare further dilutions of reference and test preparations using an isotonic non-chelating buffer containing 1 per cent of bovine or human albumin, buffered preferably between pH 7.3 and 8.0. Prepare at least three separate, independent dilutions for each material, preferably in duplicate. Prepare the dilutions such that the final factor VII concentration is below 0.005 IU/mL.

Prepare a control solution that includes all components except factor VII.

Prepare all dilutions in plastic tubes and use within 1 h.

Step 1

Mix dilutions of the factor VII reference preparation and the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C.

The concentrations of the various components during the factor Xa generation must be as specified above under the description of the reagents.

Allow the activation of factor X to proceed for a suitable time, usually terminating the reaction before the factor Xa concentration has reached its maximal level in order to obtain a satisfactory linear dose-response relationship. The activation time is also chosen to achieve linear production of factor Xa in time. Appropriate activation times are usually between 2 min and 5 min, but deviations are permissible if acceptable linearity of the dose-response relationship is thus obtained.

Step 2

Terminate the activation by the addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the

concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by the addition of a suitable reagent, such as acetic acid (500 g/L $C_2H_4O_2$) or a citrate solution (1 mol/L) at pH 3. Adjust the hydrolysis time to achieve a linear development of chromophore with time. Appropriate hydrolysis times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (for example, *5.3*).

A3. Assay of Factor VIII Fraction (Human Coagulation Factor VIII)

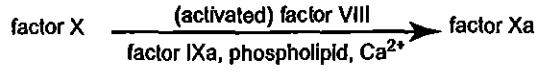
(Ph. Eur. method 2.7.4)

Human coagulation factor VIII is assayed by its biological activity as a cofactor in the activation of factor X by activated factor IX (factor IXa) in the presence of calcium ions and phospholipid. Factor VIII activity may be measured in plasma preparations and therapeutic concentrates (plasma-derived and recombinant). The potency of a factor VIII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

Quantification of factor VIII activity in plasma preparations is expressed in International Units defined by the International Standard for blood coagulation factor VIII in plasma, and *coagulation factors V, VIII, XI and XIII plasma BRP* is suitable for use as a reference preparation. Quantification of factor VIII activity in therapeutic concentrates is expressed in International Units defined by the International Standard for blood coagulation factor VIII concentrate, and *human coagulation factor VIII concentrate BRP* is suitable for use as a reference preparation.

The chromogenic assay method consists of 2 consecutive steps: the factor VIII-dependent activation of factor X in a coagulation-factor reagent composed of purified components, and the enzymatic cleavage of a chromogenic factor Xa substrate to yield a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VIII concentration. The assay is summarised by the following scheme.

Step 1



Step 2

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification. Deviations from this description may be permissible provided that it has been shown, using the appropriate International Standard for blood coagulation factor VIII as the standard, that the results obtained do not differ significantly.

It is important to demonstrate by validation the suitability of the kit used, notably by checking the time course of factor Xa generation in order to determine the time taken to reach 50 per cent of the maximal factor Xa generation.

REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X, factor IXa, and a factor VIII activator, usually thrombin. These proteins are partly purified, preferably to at least 50 per cent, and do not contain impurities that interfere with the activation of factor VIII or factor X. Thrombin may be present in its precursor form prothrombin, provided that its activation in the reagent is sufficiently rapid to give almost instantaneous activation of factor VIII in the assay. Phospholipid may be obtained from natural sources or be synthetically prepared, and must, to a substantial extent, consist of the species phosphatidylserine. The components of the complete reagent are usually divided into at least 2 separate reagents, each lacking the ability to generate factor Xa on its own. One of the reagents contains calcium ions. After reconstitution, the reagents may be combined provided that no substantial amounts of factor Xa are generated in the absence of factor VIII. In the final incubation mixture, factor VIII must be the only rate-limiting component.

The 2nd step comprises the quantification of the formed factor Xa, employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a derivatised short peptide of between 3 and 5 amino acids, joined to a chromophore group. On cleavage of this group from the peptide substrate, its chromophoric properties shift to a wavelength allowing its spectrophotometric quantification. The substrate must also contain appropriate inhibitors to stop further factor Xa generation, e.g. chelating agents, and to suppress thrombin activity.

ASSAY PROCEDURE

For the assay of therapeutic concentrates, add sufficient prediluent to the reference and test preparations to produce solutions containing 0.5-2.0 IU/mL. The prediluent consists of haemophilia A plasma, or of an artificially prepared reagent that contains sufficient von Willebrand factor and that gives results that do not differ significantly from those obtained employing haemophilia plasma. The prediluted materials must be stable beyond the time required for the assay. Pre-dilution in haemophilia A plasma is not required for the assay of factor VIII in plasma preparations.

Prepare dilutions of the pre-diluted reference and test concentrate preparations (or the reference and test plasma preparations) using a non-chelating, appropriately buffered solution, for example, tris(hydroxymethyl)aminomethane or imidazole, containing 1 per cent of human or bovine albumin. Prepare at least 2 dilution series of at least 3 further dilutions for each material. Prepare the dilutions such that the final factor VIII concentration in the reaction mixture is preferably below 0.01 IU/mL, during the step of factor Xa generation.

Prepare a control solution that includes all components except factor VIII.

Prepare all dilutions in plastic tubes and use immediately.

Step 1

Mix prewarmed dilutions of the factor VIII reference preparation and of the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C. Allow the activation of factor X to proceed for a suitable time, terminating the reaction (step 2) when the factor Xa concentration has reached approximately 50 per cent of the maximal (plateau) level. Appropriate activation times are usually between 2 min and 5 min.

Step 2

Terminate the activation by addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by addition of a suitable reagent, such as a 50 per cent *V/V* solution of acetic acid, or a 1 M pH 3 citrate buffer solution. Adjust the hydrolysis time to achieve a linear development of chromophore over time. Appropriate hydrolysis times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Calculate the potency of the test preparation by the usual statistical methods (for example, *5.3*).

A4. Assay of Factor IX Fraction (Human Coagulation Factor IX)

(Ph. Eur. method 2.7.11)

The principle of the assay is to measure the ability of a factor IX preparation to reduce the prolonged coagulation time of factor IX-deficient plasma. The reaction is accelerated by addition of a reagent containing phospholipid and a contact activator, e.g. kaolin, silica or ellagic acid. The potency is assessed by comparing the dose-response curve of the preparation to be examined to that of a reference preparation, calibrated in International Units.

The International Unit is the factor IX activity of a stated amount of the International Standard, which consists of a freeze-dried concentrate of human coagulation factor IX. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Human coagulation factor IX concentrate BRP is calibrated in International Units by comparison with the International Standard.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use immediately. Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulfate R* (10 µg of protamine sulfate neutralises 1 IU of heparin). Predilute the preparation to be examined and the reference preparation in factor IX-deficient plasma (for example *plasma substrate R2*) to produce solutions containing 0.5-2.0 IU/mL. Prepare at least 3 dilutions for each material, preferably in duplicate, using a suitable buffer solution (for example *imidazole buffer solution pH 7.3 R*) containing 10 g/L of bovine or human albumin. Use these dilutions immediately.

Use an apparatus suitable for measurement of coagulation times or carry out the assay with incubation tubes maintained in a water-bath at 37 °C. Place in each tube 0.1 mL of factor IX-deficient plasma (for example *plasma substrate R2*) and 0.1 mL of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 mL of a suitable Activated Partial Thromboplastin Time (APTT) reagent containing phospholipid and contact activator and incubate the mixture for a recommended time at 37 °C. To each tube, add 0.1 mL of a 3.7 g/L solution of *calcium chloride R* previously heated to 37 °C. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin. The volumes given above may be adapted to the APTT reagent and apparatus used. Calculate the potency using the usual statistical methods (for example, *5.3*).

A5. Assay of Human Coagulation Factor X

(Ph. Eur. method 2.7.19)

Human coagulation factor X is assayed following specific activation to form factor Xa. Factor Xa is estimated by comparing its activity in cleaving a specific chromogenic peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor X activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human coagulation factor X. The equivalence in International Units of the International Standard is stated by the World Health Organization.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor X, followed by enzymatic cleavage of a chromogenic factor Xa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor Xa activity and the cleavage of the chromogenic substrate.

REAGENTS

Russell's viper venom specific factor X activator (RVV). A protein derived from the venom of Russell's viper (*Vipera russelli*) which specifically activates factor X. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

Factor Xa chromogenic substrate Specific chromogenic substrate for factor Xa such as: *N*-α-benzyloxycarbonyl-D-arginyl-L-glycyl-L-arginine-4-nitroanilide dihydrochloride, *N*-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride, methanesulfonyl-D-leucyl-glycyl-L-arginine-4-nitroanilide, methoxycarbonyl-D-cyclohexylalanyl-glycyl-L-arginine-4-nitroanilide acetate. Reconstitute according to the manufacturer's instructions.

Dilution buffer Solution containing 3.7 g/L of *tris (hydroxymethyl)aminomethane R*, 18.0 g/L of *sodium chloride R*, 2.1 g/L of *imidazole R*, 0.02 g/L of *hexadimethrine bromide R* and 1 g/L of *bovine albumin R* or *human albumin R*. Adjust to pH 8.4 if necessary using *hydrochloric acid R*.

METHOD

Test solution Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Reference solution Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 12.5 µL of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 25 µL of RVV and incubate for exactly 90 s. To each well add 150 µL of factor Xa chromogenic substrate, diluted 1 in 6 in dilution buffer.

Read the rate of change of absorbance (*2.2.25*) (at 405 nm continuously over a period of 3 min and obtain the mean rate of change of absorbance (ΔA/min). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate ΔA/min as the slope of the line. From the ΔA/min values of each individual dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (*5.3*).

A6. Assay of Human Coagulation Factor XI

(Ph. Eur. method 2.7.22)

The principle of the assay is to measure the ability of a factor XI preparation to reduce the prolonged coagulation time of factor XI-deficient plasma. The reaction is accelerated by addition of a reagent containing phospholipid and a contact activator, e.g. kaolin, silica or ellagic acid. The potency is assessed by comparing the dose-response curve of the preparation to be examined to that of a reference plasma calibrated against the International Standard for blood coagulation factor XI in plasma.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use immediately. *Coagulation factors V, VIII, XI and XIII plasma BRP* is suitable for use as a reference preparation. Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulfate R* (10 µg of protamine sulfate neutralises 1 IU of heparin). Predilute the preparation to be examined and the reference preparation in factor XI-deficient plasma (for example *plasma substrate R3*) to produce solutions containing 0.5-2.0 units/mL. Prepare at least 3 appropriate dilutions for each material, preferably in duplicate, using a suitable buffer solution (for example *imidazole buffer solution pH 7.3 R*) containing 10 g/L of bovine or human albumin. Use these dilutions immediately.

Use an apparatus suitable for measurement of coagulation times or perform the assay with incubation tubes maintained in a water bath at 37 °C. Place in each tube 0.1 mL of factor XI-deficient plasma (for example *plasma substrate R3*) and 0.1 mL of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 mL of a suitable Activated Partial Thromboplastin Time (APTT) reagent containing phospholipid and contact activator and incubate the mixture for a recommended time at 37 °C. To each tube, add 0.1 mL of a 3.7 g/L solution of *calcium chloride R* previously heated to 37 °C. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin. The volumes given above may be adapted to the APTT reagent and apparatus used. Calculate the potency using the usual statistical methods (for example, *5.3*).

A7. Activated Coagulation Factors

(Ph. Eur. method 2.6.22)

Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulfate R* (10 µg of protamine sulfate neutralises 1 IU of heparin). Prepare 1 to 10 and 1 to 100 dilutions of the preparation to be examined using *tris(hydroxymethyl) aminomethane buffer solution pH 7.5 R*. Place a series of polystyrene tubes in a water-bath at 37 °C and add to each tube 0.1 mL of *platelet-poor plasma R* and 0.1 mL of a suitable dilution of a phospholipid preparation to act as a platelet substitute. Allow to stand for 60 s. Add to each tube either 0.1 mL of 1 of the dilutions or 0.1 mL of the buffer solution (control tube). To each tube add immediately 0.1 mL of a 3.7 g/L solution of *calcium chloride R* previously heated to 37 °C, and measure, within 30 min of preparing the original dilution, the time that elapses between addition of the calcium chloride solution and the formation of a clot. The test is not valid unless the coagulation time measured for the control tube is 200 s to 350 s.

A8. Assay of Human von Willebrand Factor

(Ph. Eur. method 2.7.21)

The biological functions of human von Willebrand factor are numerous. At present, its ristocetin cofactor activity and its collagen binding activity can be utilised for assays.
The potency of human von Willebrand factor is determined by comparing, in given conditions, its activity with the same activity of a reference preparation calibrated against the International Standard, in International Units where applicable.

The International Unit is the activity of a stated amount of the International Standard, which consists of a freeze-dried human von Willebrand factor concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organization (WHO).

RISTOCETIN COFACTOR ASSAY

The ristocetin cofactor activity of von Willebrand factor is determined by measuring agglutination of a suspension of platelets in the presence of ristocetin A. The assay can be carried out for quantitative determinations by using automated instruments, or for semi-quantitative determinations by visually assessing the endpoint of agglutination in a dilution series. Quantitative assays are preferred.

REAGENTS

Suspension of platelets Use standardised and, for example, formaldehyde- or paraformaldehyde-fixed preparations of freshly isolated and washed human platelets. The suspension may also be freeze-dried. An appropriate amount of ristocetin A is added if necessary. Some platelet reagents may already contain ristocetin A.

Reference preparation The reference preparation for von Willebrand factor is the WHO International Standard for von Willebrand factor concentrate.

METHOD

Semi-quantitative assay Prepare suitable dilutions of the preparation to be examined and of the reference preparation, using as diluent a solution containing 9 g/L of *sodium*

chloride R and 10-50 g/L of *human albumin R*. Add to each dilution an appropriate amount of the suspension of platelets and, if necessary, of ristocetin A. Mix on a glass slide by moving it gently in circles for 1 min. Allow to stand for a further 1 min and read the result against a dark background with side lighting. The last dilution which clearly shows visible agglutination indicates the ristocetin cofactor titre of the sample. Use diluent as a negative control.

Quantitative Assay Reconstitute the entire contents of 1 ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of the recommended diluent (for example *water R*); use immediately. Add sufficient prediluent to the reconstituted preparations to produce solutions containing 0.5-2.0 IU/mL. The prediluent consists of an isotonic non-chelating buffer containing, for example, 1-5 per cent of human or bovine albumin, and tris(hydroxymethyl)aminomethane or imidazole, appropriately buffered.

The test is performed in accordance with the manufacturer's instructions with at least 2 dilution series with as many dilutions as are needed to obtain a total of at least 3 different concentrations in the linear range of the assay.

Check the validity of the assay and calculate the potency of the test preparation using the usual statistical methods (for example, *5.3*).

COLLAGEN-BINDING ASSAY

Collagen-binding is determined by an enzyme-linked immunosorbent assay on collagen-coated microtitre plates. The method is based on the specific binding of von Willebrand factor to collagen fibrils and the subsequent binding of polyclonal anti-von Willebrand factor antibody conjugated to an enzyme, which on addition of a chromogenic substrate yields a product that can be quantitated spectrophotometrically. Under appropriate conditions, there is a linear relationship between von Willebrand factor collagen-binding and absorbance.

REAGENTS

Collagen Use native equine or human fibrils of collagen type I or III. For ease of handling, collagen solutions may be used.

Collagen diluent Dissolve 50 g of *glucose R* in *water R*, adjust to pH 2.7-2.9 with *1 M hydrochloric acid* and dilute to 1000 mL with *water R*.

Phosphate-buffered saline (PBS) Dissolve 8.0 g of *sodium chloride R*, 1.05 g of *disodium hydrogen phosphate dihydrate R*, 0.2 g of *sodium dihydrogen phosphate R* and 0.2 g of *potassium chloride R* in *water R*. Adjust to pH 7.2 using *1 M sodium hydroxide* or *1 M hydrochloric acid* and dilute to 1000 mL with *water R*.

Washing buffer PBS containing 1 g/L of *polysorbate 20 R*.

Blocking reagent PBS containing 1 g/L of *polysorbate 20 R* and 10 g/L of *bovine albumin R*.

Dilution buffer PBS containing 1 g/L of *polysorbate 20 R* and 50 g/L of *bovine albumin R*.

Conjugate Rabbit anti-human von Willebrand factor serum horseradish peroxidase conjugate. Use according to the manufacturer's instructions.

Substrate solution Immediately before use, dissolve a tablet of *o*-phenylenediamine dihydrochloride and a tablet of urea hydrogen peroxide in 20 mL of *water R* or use a suitable volume of hydrogen peroxide. Protect from light.

Microtitre plates Flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity.

METHOD

Test solutions Reconstitute the preparation to be examined as stated on the label. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 series of at least 3 further dilutions using dilution buffer.

Reference solutions Reconstitute the reference preparation as directed. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 series of at least 3 further dilutions using dilution buffer.

Allow the solution of collagen to warm to room temperature. Dilute with collagen diluent to obtain a solution containing 30-75 µg/mL of collagen, mix gently to produce a uniform suspension of collagen fibrils. Pipette 100 µL into each well of the microtitre plate. Cover the plate with plastic film and incubate at 37 °C overnight. Empty the wells of the collagen-coated plate by inverting and draining on a paper towel. Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times. Add 250 µL of blocking reagent to each well, cover the plate with plastic film and incubate at 37 °C for 1 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µL each of the test solutions or reference solutions to the wells. Add 100 µL of dilution buffer to a series of wells to serve as negative control. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel.
Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Prepare a suitable dilution of the conjugate (for example, a dilution factor of 1 to 4000) with PBS containing 5 g/L of *bovine albumin R* and add 100 µL to each well. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µL of substrate solution to each of the wells and incubate at room temperature for 20 min in the dark.
Add 100 µL of *1 M hydrochloric acid* to each of the wells.

Measure the absorbance at 492 nm. Use the absorbance values to estimate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

The assay is invalid if the absorbances measured for the negative controls are greater than 0.05.

A9. Test for Prekallikrein Activator

(Ph. Eur. method 2.6.15)

Prekallikrein activator (PKA) activates prekallikrein to kallikrein and may be assayed by its ability to cleave a chromophore from a synthetic peptide substrate so that the rate of cleavage can be measured spectrophotometrically and the concentration of PKA calculated by comparison with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of the International Standard, which consists of freeze-dried prekallikrein activator. The equivalence in International Units

of the International Standard is stated by the World Health Organization.

REAGENTS

Prekallikrein activator in albumin BRP is calibrated in International Units by comparison with the International Standard.

Buffer A Dissolve 6.055 g of *tris(hydroxymethyl) aminomethane R*, 1.17 g of *sodium chloride R*, 50 mg of *hexadimethrine bromide R* and 0.100 g of *sodium azide R* in *water R*. Adjust to pH 8.0 with *2 M hydrochloric acid R* and dilute to 1000 mL with *water R*.

Buffer B Dissolve 6.055 g of *tris(hydroxymethyl) aminomethane R* and 8.77 g of *sodium chloride R* in *water R*. Adjust to pH 8.0 with *2 M hydrochloric acid R* and dilute to 1000 mL with *water R*.

PREPARATION OF PREKALLIKREIN SUBSTRATE

To avoid coagulation activation, blood or plasma used for the preparation of prekallikrein must come into contact only with plastics or silicone-treated glass surfaces.

Draw 9 volumes of human blood into 1 volume of anticoagulant solution (ACD, CPD or a 38 g/L solution of *sodium citrate R*) to which 1 mg/mL of *hexadimethrine bromide R* has been added. Centrifuge the mixture at 3600 *g* for 5 min. Separate the plasma and centrifuge again at 6000 *g* for 20 min to sediment platelets. Separate the platelet-poor plasma and dialyse against 10 volumes of buffer A for 20 h. Apply the dialysed plasma to a chromatography column containing agarose-DEAE for ion-exchange chromatography R that has been equilibrated in buffer A and is equal to twice the volume of the plasma. Elute from the column with buffer A at 20 mL/cm^2/h. Collect the eluate in fractions and record the absorbance at 280 nm (*2.2.25*). Pool the fractions containing the 1st protein peak so that the volume of the pool is about 1.2 times the volume of the platelet-poor plasma.

Test the substrate pool for absence of kallikrein activity by mixing 1 part with 20 parts of the pre-warmed chromogenic substrate solution to be used in the assay and incubate at 37 °C for 2 min. The substrate is suitable if the increase in absorbance is less than 0.001 per minute. Add to the pooled solution 7 g/L of *sodium chloride R* and filter through a membrane filter (nominal pore size 0.45 µm). Freeze the filtrate in portions and store at −25 °C; the substrate may be freeze-dried before storage.

Carry out all procedures from the beginning of the chromatography to freezing in portions during a single working day.

METHOD

The assay may be carried out using an automated enzyme analyser or a suitable microtitre plate system allowing kinetic measurements, with appropriate software for calculation of results. Standards, samples and prekallikrein substrate may be diluted as necessary using buffer B.

Incubate diluted standards or samples with prekallikrein substrate for 10 min such that the volume of the undiluted sample does not exceed 1/10 of the total volume of the incubation mixture to avoid errors caused by variation in ionic strength and pH in the incubation mixture. Incubate the mixture or a part thereof with at least an equal volume of a solution of a suitable synthetic chromogenic substrate, known to be specific for kallikrein (for example, *N-benzoyl-L-prolyl-L-phenylalanyl-L-arginine 4-nitroanilide acetate R* or D-prolyl-L-phenylalanyl-L-arginine 4-nitroanilide dihydrochloride R), dissolved in buffer B. Record the rate of change in absorbance per minute for 2-10 min at the wavelength specific for the substrate used. Prepare a blank for each mixture of sample or standard using buffer B instead of prekallikrein substrate.

Depending on the method used, ΔA/min has to be corrected by subtracting the value obtained for the corresponding blank without the prekallikrein substrate. The results may be calculated using a standard curve, a parallel-line or a slope ratio assay or any other suitable statistical method. Plot a calibration curve using the values thus obtained for the reference preparation and the respective concentrations; use the curve to determine the PKA activity of the preparation to be examined. During method validation, the spiking experiments must show that the sample matrix has no influence on the results. High blank values may impact assay validity and should be appropriately investigated.

A10. Assay of Human Plasmin Inhibitor

(Ph. Eur. method 2.7.25)

Human plasmin inhibitor, also called human α_2-antiplasmin, is a plasma protein that inhibits the plasmin (a serine protease) pathway of fibrinolysis by rapidly forming a complex with free plasmin. Furthermore, upon blood coagulation, human plasmin inhibitor is cross-linked to fibrin strands by factor XIII, and interferes with binding of the proenzyme plasminogen to fibrin.

The potency of human plasmin inhibitor is estimated by comparing the ability of the preparation to be examined to inhibit the cleavage of a specific chromogenic substrate by plasmin with the same ability of a reference standard of human plasmin inhibitor. Plasmin cleavage of the chromogenic substrate yields a chromophore that can be quantified spectrophotometrically.

The individual reagents for the assay may be obtained separately or in commercial kits. Both end-point and kinetic methods are available. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example of a microtitre-plate kinetic method.

REAGENTS

Dilution buffer pH 7.5 According to the manufacturer's instructions, a suitable buffer is used. Adjust the pH if necessary.

Plasmin A preparation of human plasmin that does not contain significant amounts of other proteases is preferably used. Reconstitute and store according to the manufacturer's instructions.

Plasmin chromogenic substrate A suitable specific chromogenic substrate for plasmin is used: H-D-cyclohexylalanyl-norvalyl-lysyl-*p*-nitroaniline hydrochloride (H-D-CHA-Nva-Lys-*p*NA.HCl) or L-pyroglutamyl-L-phenylalanyl-L-lysyl-*p*-nitroaniline hydrochloride (Glp-Phe-Lys-*p*NA.HCl). Reconstitute in *water R* to give a suitable concentration according to the manufacturer's instructions.

METHOD

Varying quantities of the preparation to be examined are mixed with a given quantity of plasmin and the remaining plasmin activity is determined using a suitable chromogenic substrate.

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with dilution buffer pH 7.5 and prepare at least 2 independent series of 3 or 4 dilutions for both the preparation to be examined and the reference standard.

Mix 0.020 mL of each dilution with 0.020 mL of dilution buffer pH 7.5 and warm to 37 °C. Add 0.040 mL of a plasmin solution (test concentration in the range of 0.2 nkat/mL to 1.6 nkat/mL) previously heated to 37 °C and leave at 37 °C for 1 min. Add 0.020 mL of the chromogenic substrate solution, previously heated to 37 °C, to each mixture. Immediately start measurement of the change in absorbance at 405 nm (*2.2.25*) using a microtitre plate reader. Calculate the rate of change of absorbance (ΔA/min). Alternatively, an end-point assay might be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm.

In both cases the duration of the cleavage of the chromogenic substrate should be chosen to produce a linear increase in absorbance at 405 nm, before substrate depletion becomes significant. If the assay is performed in test tubes or cuvettes using a spectrophotometric method, the volumes of reagent solutions are changed proportionally.

Substract the optical density of the blank (prepared with dilution buffer pH 7.5) from the optical density of the preparation to be examined. Check the validity of the assay and calculate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

Anticoagulants

B1. Assay of Heparin in Coagulation Factors

(Ph. Eur. method 2.7.12)

Heparin is assayed as a complex with antithrombin III (AT) via its inhibition of coagulation factor Xa (anti-Xa activity). An excess of AT is maintained in the reaction mixture to ensure a constant concentration of the heparin-AT complex. Factor Xa is neutralised by the heparin-AT complex and the residual factor Xa hydrolyses a specific chromogenic peptide substrate to release a chromophore. The quantity of chromophore is inversely proportional to the activity of the heparin.

Factor Xa chromogenic substrate Specific chromogenic substrate for factor Xa such as: *N*-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride. Reconstitute according to the manufacturer's instructions.

Dilution buffer 6.05 g/L solution of *tris(hydroxymethyl) aminomethane R*. Adjust to pH 8.4 if necessary using *hydrochloric acid R*.

Test solution Dilute the preparation to be examined with dilution buffer to obtain a solution expected to contain 0.1 IU of heparin per millilitre.

Reference solution Dilute the heparin reference preparation with dilution buffer to obtain a solution containing 0.1 IU of heparin per millilitre.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Warm all solutions to 37 °C in a water-bath shortly before the test.

Distribute in a series of wells, 20 µL of normal human plasma and 20 µL of *antithrombin III solution R1*. Add to the wells a series of volumes (20 µL, 60 µL, 100 µL and 140 µL) of the test solution or the reference solution and make up the volume in each well to 200 µL using dilution buffer (0.02-0.08 IU of heparin per millilitre in the final reaction mixture).

End-point method Transfer 40 µL from each well to a second series of wells, add 20 µL of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µL of a 1 mmol/L solution of factor Xa chromogenic substrate and incubate at 37 °C for 3 min. Terminate the reaction by lowering the pH by the addition of a suitable reagent, such as a 20 per cent *V/V* solution of *glacial acetic acid R* and measure the absorbance at 405 nm (*2.2.25*). Appropriate reaction times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Kinetic method Transfer 40 µL from each well to a second series of wells, add 20 µL of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µL of a 2 mmol/L solution of factor Xa chromogenic substrate, incubate at 37 °C and measure the rate of substrate cleavage by continuous measurement of the absorbance change at 405 nm (*2.2.25*), thus allowing the initial rate of substrate cleavage to be calculated. This rate must be linear with the concentration of residual factor Xa.

Check the validity of the assay and calculate the heparin activity of the test preparation by the usual statistical methods for a slope-ratio assay (for example, *5.3*).

B2. Assay of Heparin

(Ph. Eur. method 2.7.5)

The anticoagulant activity of heparin is determined *in vitro* by its ability to accelerate the inhibition of thrombin, factor IIa (anti-IIa assay), by antithrombin. The International Unit is the activity contained in a stated amount of the International Standard for unfractionated heparin. *Heparin sodium BRP*, calibrated in International Units by comparison with the International Standard using the 2 assays given below, is used as the reference preparation.

The assay of anti-factor Xa activity is carried out to determine the ratio of anti-factor Xa activity to anti-factor IIa activity.

For anti-IIa and anti-Xa assays, carry out the assay by determining the absorbance (end-point method) or the change of absorbance per minute (kinetic method).

ANTI-FACTOR IIA ACTIVITY

Reference and test solutions

Prepare 4 independent series of 4 dilutions each of the substance to be examined and of *heparin sodium BRP* in *tris (hydroxymethyl) aminomethane-EDTA buffer solution pH 8.4 R1*; a concentration range within 0.005 IU and 0.03 IU per millilitre is suitable. The dilutions chosen must give a linear response when results are plotted as absorbance against log concentration.

Procedure

Label 16 tubes for the dilutions of the substance to be examined and 16 tubes for the dilutions of the reference preparation: T_1, T_2, T_3, T_4 for each of the 4 series of dilutions of the substance to be examined and S_1, S_2, S_3, S_4 for each of the 4 series of dilutions of the reference preparation. To each of the 32 tubes add 100 µL of *antithrombin III solution R5* and 50 µL of the appropriate dilution of the substance to be examined or the reference preparation. After each addition, mix but do not allow bubbles to form. Treating the tubes in 2 subsequent series in the order S_1, S_2, S_3, S_4, T_1, T_2, T_3, T_4, T_1, T_2, T_3, T_4, S_1, S_2, S_3, S_4, allow to equilibrate at 37 °C (water-bath or heating block) for at least 1 min and add to each tube 25 µL of *human thrombin solution R2*. Incubate for exactly 1 min and add 50 µL of a chromogenic substrate specific to factor IIa at a concentration suitable for the assay (for example, D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide

dihydrochloride dissolved in *water R* to give a 1.25 mM solution).

For the kinetic method, transfer the mixtures to semi-micro cuvettes and measure the change in absorbance per minute (*2.2.25*) at 405 nm using a suitable reading device.

For the end-point method, stop the reaction after exactly 4 min by adding 50 µL of a 20 per cent *V/V* solution of *glacial acetic acid R*. Assess whether exactly 4 min of incubation with the chromogenic substrate yields the optimal absorbance reading and, if necessary, adjust the incubation time to give the best dose-response curve. Then, transfer the mixtures to semi-micro cuvettes and measure the absorbance (*2.2.25*) at 405 nm using a suitable reading device.

Determine the blank amidolytic activity at the beginning and at the end of the procedure in a similar manner, using *tris (hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R1* instead of the reference and test solutions; the 2 blank values do not differ significantly.

Calculate the regression of the absorbance on log concentrations of the solutions of the substance to be examined and of *heparin sodium BRP*, and calculate the potency of the substance to be examined in International Units per millilitre using the usual statistical methods for parallel-line assays (*5.3*).

ANTI-FACTOR XA ACTIVITY

Reference and test solutions

Prepare 4 independent series of 4 dilutions each of the substance to be examined and of *heparin sodium BRP* in *tris (hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R1*; a concentration range within 0.03 IU and 0.375 IU per millilitre is suitable. The dilutions chosen must give a linear response when results are plotted as absorbance against log concentration.

Procedure

Label 16 tubes for the dilutions of the substance to be examined and 16 tubes for the dilutions of the reference preparation: T_1, T_2, T_3, T_4 for each of the 4 series of dilutions of the substance to be examined and S_1, S_2, S_3, S_4 for each of the 4 series of dilutions of the reference preparation. To each of the 32 tubes add 50 µL of *antithrombin III solution R6* and 50 µL of the appropriate dilution of the substance to be examined or the reference preparation. After each addition, mix but do not allow bubbles to form. Treating the tubes in 2 subsequent series in the order S_1, S_2, S_3, S_4, T_1, T_2, T_3, T_4, T_1, T_2, T_3, T_4, S_1, S_2, S_3, S_4, allow to equilibrate at 37 °C (water-bath or heating block) for 1 min and add to each tube 100 µL of *bovine factor Xa solution R2*. Incubate for exactly 2 min and add 100 µL of a chromogenic substrate specific to factor Xa at a concentration suitable for the assay (for example, *N*-α-benzyloxycarbonyl-D-arginyl-L-glycyl-L-arginine-4-nitroanilide dihydrochloride dissolved in *water R* to give a 1 mM solution).

For the kinetic method, transfer the mixtures to semi-micro cuvettes and measure the change in absorbance per minute (*2.2.25*) at 405 nm using a suitable reading device.

For the end-point method, stop the reaction after exactly 4 min by adding 50 µL of a 20 per cent *V/V* solution of *glacial acetic acid R*. Assess whether exactly 4 min of incubation with the chromogenic substrate yields the optimal absorbance reading and, if necessary, adjust the incubation time to give the best dose-response curve. Then, transfer the mixtures to semi-micro cuvettes and measure the absorbance (*2.2.25*) at 405 nm using a suitable reading device.

Determine the blank amidolytic activity at the beginning and at the end of the procedure in a similar manner, using *tris (hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R1* instead of the reference and test solutions; the 2 blank values do not differ significantly.

Calculate the regression of the absorbance on log concentrations of the solutions of the substance to be examined and of *heparin sodium BRP*, and calculate the potency of the substance to be examined in International Units per millilitre using the usual statistical methods for parallel-line assays (*5.3*).

B3. Assay of Human Antithrombin III

(Ph. Eur. method 2.7.17)

The antithrombin III content of the preparation to be examined is determined by comparing its ability to inactivate thrombin in the presence of an excess of heparin with the same ability of a reference preparation of human antithrombin III concentrate calibrated in International Units. Varying quantities of the preparation to be examined are mixed with a given quantity of thrombin and the remaining thrombin activity is determined using a suitable chromogenic substrate.

The International Unit is the activity of a stated amount of the International Standard for human antithrombin III concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Method Prepare 2 independent series of 3 or 4 dilutions in the range 1/75 to 1/200 from 1 IU/mL, for both the preparation to be examined and the reference preparation, using *tris-EDTA BSA buffer solution pH 8.4 R* containing 15 IU of heparin per millilitre.

Warm 200 µL of each dilution at 37 °C for 1-2 min. Add to each dilution 200 µL of a solution of *bovine thrombin R* containing 2 IU/mL in *tris-EDTA BSA buffer solution pH 8.4 R*. Mix and maintain at 37 °C for exactly 1 min. Add 500 µL of a suitable chromogenic substrate (for example, D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide, reconstituted in *water R* to give a solution containing 4 mmol/L and further diluted to a concentration suitable for the assay using *tris-EDTA BSA buffer solution pH 8.4 R* without albumin). Immediately start measurement of the change in absorbance at 405 nm (*2.2.25*), continuing the measurement for at least 30 s. Calculate the rate of change of absorbance (ΔA/min). (Alternatively, an end-point assay may be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm.)

The rate of change of absorbance (ΔA/min) is inversely proportional to antithrombin III activity.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (*5.3*).

B4. Assay of Human Protein C

(Ph. Eur. method 2.7.30)

1. CHROMOGENIC ASSAY

Human protein C is a vitamin K-dependent plasma protein that, upon activation to activated protein C (APC), can inhibit blood coagulation through the proteolytic cleavage of factors Va and VIIIa. Human protein C activity is estimated using a two-step method: in the 1st step, human protein C in the preparation is activated by a specific activator from snake venom; in the 2nd step, APC cleaves a specific chromogenic substrate to form a chromophore that can be quantified spectrophotometrically.

Step 1

Step 2

The potency of human protein C is estimated by comparing the ability of the preparation to be examined to cleave a chromogenic substrate with the same ability of a reference standard of human protein C calibrated in International Units. The International Unit is the activity of a stated amount of the International Standard for human protein C. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Individual reagents may be obtained separately or in commercial kits. Both end-point and kinetic methods are available. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example of a microtitre plate end-point method.

REAGENTS

Dilution buffer pH 8.4 Dissolve 6.055 g of *tris (hydroxymethyl)aminomethane R* and 16.84 g of *caesium chloride R* in *water R* and adjust the pH if necessary. Dilute to 1000.0 mL with *water R*.

Human protein C activator Protein isolated from the venom of the viper *Agkistrodon contortrix contortrix* that specifically activates human protein C. Reconstitute and store according to the manufacturer's instructions. Dilute to 0.25 U/mL with *water R* before use in the assay.

Activated protein C chromogenic substrate Specific chromogenic substrate for APC, for example L-pyroglutamyl-L-prolyl-L-arginyl-*p*-nitroaniline hydrochloride (pyroGlu-Pro-Arg-pNA.HCl). Reconstitute with *water R* to give a concentration of 4.5 mmol/L. Further dilute to 1.1 mmol/L with dilution buffer pH 8.4 before use in the assay.

METHOD

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with *water R* to produce at least 3 separate dilutions for each preparation in the range 0.050-0.200 IU/mL, preferably in duplicate.

Step 1

Mix 0.025 mL of each dilution with 0.050 mL of the human protein C activator, both previously heated to 37 °C, and leave at 37 °C for exactly 10 min. For each dilution, prepare a blank in the same manner, using *water R* instead of the human protein C activator.

Step 2

Add 0.150 mL of diluted chromogenic substrate, previously heated to 37 °C, to each mixture and leave at 37 °C for exactly 10 min. The incubation time must be adjusted, if necessary, to ensure a linear development of chromophore with time. Terminate the reaction by adding 0.050 mL of a 50 per cent *V/V* solution of *glacial acetic acid R*.

Cleavage of the chromogenic substrate by APC causes release of the chromophore pNA, in proportion to the concentration of human protein C in the preparation. Measure the optical density at a wavelength of 405 nm. Subtract the optical density of the blank from the optical density of the test sample. Check the validity of the assay and calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

2. CLOTTING ASSAY

Human protein C activity is estimated following cleavage to APC by a specific activator extracted from the venom of the viper *Agkistrodon contortrix contortrix*. The resulting APC inactivates factors Va and VIIIa, and thus prolongs the APTT (Activated Partial Thromboplastin Time) of a system in which all the coagulation factors are present, constant and in excess, except for human protein C, which is derived from the preparation being tested. Prolongation of the clotting time is proportional to the concentration of human protein C in the preparation.

The potency of human protein C is estimated by comparing the ability of the preparation to be examined to prolong the clotting time with the same ability of a reference standard of human protein C calibrated in International Units.
The International Unit is the activity of a stated amount of the International Standard for human protein C.
The equivalence in International Units of the International Standard is stated by the World Health Organization.

Individual reagents may be obtained separately or in commercial kits. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example.

REAGENTS

Dilution buffer pH 7.4 Isotonic non-chelating buffer.

Human protein C-deficient plasma Citrated human plasma with no measurable human protein C content. Reconstitute and store according to the manufacturer's instructions.

Human protein C activator Protein isolated from the venom of the viper *Agkistrodon contortrix contortrix* that specifically activates human protein C. Reconstitute and store according to the manufacturer's instructions.

Coagulation activator A suitable APTT reagent containing phospholipids and a contact activator may be used. It may be combined with the human protein C activator.

METHOD

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with dilution buffer pH 7.4 to produce at least 3 separate dilutions for each preparation in the range 0.010-0.150 IU/mL, preferably in duplicate.

Mix 1 volume of each dilution with 1 volume of human protein C-deficient plasma and 1 volume of the human protein C activator (combined with the APTT reagent where appropriate), all previously heated to 37 °C. Add 1 volume of 0.025 M calcium chloride solution R previously heated to 37 °C, and record the clotting time.

The clotting time is proportional to the concentration of human protein C in each dilution. Check the validity of the assay and calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

B5. Assay of Human Protein S

(Ph. Eur. method 2.7.31)

Human protein S is a vitamin K-dependent plasma protein that acts as a cofactor for the anticoagulant functions of activated protein C (APC). Human protein S activity may be determined by the clotting assay described below, which is sensitive to the ability of human protein S to accelerate the inactivation of factor Va by APC. In practice, the assay involves the addition of human protein S to a reagent mixture containing APC, factor Va and human protein S-deficient plasma. Prolongation of the clotting time is proportional to the concentration of human protein S in the preparation. Methods in which APC is added directly as a reagent are preferred to those in which APC is generated during the assay by the addition of a specific human protein C activator purified from snake venom. Activation of coagulation is initiated by the addition of an activating reagent such as thromboplastin or activated factor X, together with phospholipids and calcium chloride. During the assay, factor Va is generated from factor V in the human protein S-deficient plasma following the activation of coagulation. The assay procedure must ensure that human protein S is the only limiting factor.

The potency of human protein S is estimated by comparing the ability of the preparation to be examined to prolong the clotting time with the same ability of a reference standard of human protein S calibrated in International Units.
The International Unit is the activity of a stated amount of the International Standard for human protein S.
The equivalence in International Units of the International Standard is stated by the World Health Organization.

Individual reagents may be obtained separately or in commercial kits. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example.

REAGENTS

Dilution buffer pH 7.4 Isotonic non-chelating buffer prepared as follows: dissolve 6.08 g of *tris(hydroxymethyl) aminomethane R* and 8.77 g of *sodium chloride R* in *water R* and adjust the pH if necessary; add 10 g of *bovine albumin R* or *human albumin R* and dilute to 1000.0 mL with *water R*.

Human protein S-deficient plasma Citrated human plasma with no measurable human protein S content and, preferably, also free of C4b-binding protein.

Coagulation activator This reagent is used to initiate coagulation in the human protein S-deficient plasma, and thereby also provides a source of activated factor V.
The activator may consist of tissue factor, activated factor X, or an agent capable of directly activating factor X that may be purified from the venom of Russell's viper (*Vipera russelli*).
The reagent also contains APC, phospholipids and *calcium chloride R*, or, alternatively, calcium chloride may be added separately after a timed activation period.

METHOD

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with dilution buffer pH 7.4 to produce at least 3 separate dilutions for each preparation in the range 0.020-0.100 IU/mL, preferably in duplicate.

Mix 1 volume of each dilution with 1 volume of human protein S-deficient plasma, both previously heated to 37 °C. Add 2 volumes of the coagulation activator, previously heated to 37 °C, and record the clotting time.

Alternative procedures may use a coagulation activator without calcium chloride, and require a precisely timed activation period before the addition of calcium chloride and the measurement of clotting time.

The clotting time is proportional to the concentration of human protein S in each dilution. Check the validity of the assay and calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

Immunoglobulins

C1. Test for Fc Function of Immunoglobulin

(Ph. Eur. method 2.7.9)

The test for Fc function of immunoglobulin is carried out using method A or B. Method B is an adaptation of the procedure of method A for the use of microtitre plates for the measurement of complement-mediated haemolysis. Differences in the test procedures between methods A and B are addressed in the test.

REAGENTS

Stabilised human blood Collect group O human blood into ACD anticoagulant solution. Store the stabilised blood at 4 °C for not more than 3 weeks.

Phosphate-buffered saline pH 7.2 Dissolve 1.022 g of *anhydrous disodium hydrogen phosphate R*, 0.336 g of *anhydrous sodium dihydrogen phosphate R* and 8.766 g of *sodium chloride R* in 800 mL of *water R* and dilute to 1000 mL with the same solvent.

Magnesium and calcium stock solution Dissolve 1.103 g of *calcium chloride R* and 5.083 g of *magnesium chloride R* in *water R* and dilute to 25 mL with the same solvent.

Barbital buffer stock solution Dissolve 207.5 g of *sodium chloride R* and 25.48 g of *barbital sodium R* in 4000 mL of *water R* and adjust to pH 7.3 using *1 M hydrochloric acid.* Add 12.5 mL of magnesium and calcium stock solution and dilute to 5000 mL with *water R*. Store at 4 °C in transparent containers.

Albumin barbital buffer solution Dissolve 0.150 g of *bovine albumin R* in 20 mL of barbital buffer stock solution and dilute to 100 mL with *water R*. Prepare immediately before use.

Tannic acid solution Dissolve 10 mg of *tannic acid R* in 100 mL of phosphate-buffered saline pH 7.2. Prepare immediately before use.

Guinea-pig complement Prepare a pool of serum from the blood of not fewer than 10 guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store the serum in small amounts below −70 °C. Immediately before starting complement-initiated haemolysis, dilute to 125-200 CH_{50} per millilitre with albumin barbital buffer solution and store in an ice-bath during the test.

Rubella antigen Suitable rubella antigen for haemagglutination-inhibition titre (HIT).
Titre > 256 HA units.

Preparation of tanned human red blood cells

Separate human red blood cells by centrifuging an appropriate volume of stabilised human blood, wash the cells at least 3 times with phosphate-buffered saline pH 7.2 and suspend at 2 per cent *V/V* in phosphate-buffered saline pH 7.2. Add 0.2 mL of tannic acid solution to 14.8 mL of phosphate-buffered saline pH 7.2. Mix 1 volume of the freshly prepared dilution with 1 volume of the human red blood cell suspension and incubate at 37 °C for 10 min. Collect the cells by centrifugation (800 *g* for 10 min), discard

the supernatant and wash the cells once with phosphate-buffered saline pH 7.2. Resuspend the tanned cells at 1 per cent *V/V* in phosphate-buffered saline pH 7.2.

Antigen coating of tanned human red blood cells

Take a suitable volume (V_s) of tanned cells, add 0.2 mL of rubella antigen per 1.0 mL of tanned cells and incubate at 37 °C for 30 min. Collect the cells by centrifugation (800 *g* for 10 min) and discard the supernatant. Add a volume of albumin barbital buffer solution equivalent to the discarded supernatant, resuspend and collect the cells as described and repeat the washing procedure. Resuspend with albumin barbital buffer solution using a volume equivalent to 3/4 of V_s, thereby obtaining the initial volume (V_i). Mix 900 µL of albumin barbital buffer solution with 100 µL of V_i, which is thereby reduced to the residual volume (V_r), and determine the initial absorbance at 541 nm (A). Dilute V_r by a factor equal to A using albumin barbital buffer solution, thereby obtaining the final adjusted volume $V_f = V_r \times A$ of sensitised human red blood cells and adjusting A to 1.0 ± 0.1 for a tenfold dilution.

Antibody binding of antigen-coated tanned human red blood cells

Prepare the following solutions in succession and in duplicate, using for each solution a separate half-micro cuvette (for example, disposable type) or test-tube.

(1) *Test solutions.* If necessary, adjust the immunoglobulin to be examined to pH 7.

Where method A is performed, dilute volumes of the preparation to be examined with albumin barbital buffer to obtain 30 mg and 40 mg of immunoglobulin and adjust the volume to 900 µL with albumin barbital buffer.

Where method B is performed, dilute volumes of the preparation to be examined with albumin barbital buffer to obtain 15 mg and 30 mg of immunoglobulin and adjust the volume to 1200 µL with albumin barbital buffer.

(2) *Reference solutions.* Prepare as for the test solutions using *human immunoglobulin for Fc function BRP.*

(3) *Complement control.* Albumin barbital buffer solution.

Where method A is performed, add to each cuvette/test-tube 100 µL of sensitised human red blood cells and mix well. Allow to stand for 15 min, add 1000 µL of albumin barbital buffer solution, collect the cells by centrifugation (1000 *g* for 10 min) of the cuvette/test-tube and remove 1900 µL of the supernatant. Replace the 1900 µL with albumin barbital buffer solution and repeat the whole of the washing procedure, finally leaving a volume of 200 µL. Test samples may be stored in sealed cuvettes/test-tubes at 4 °C for not longer than 24 h.

Where method B is performed, add to each test-tube 300 µL of sensitised human red blood cells and mix well (the final immunoglobulin concentration is in the range of 10-20 mg/mL). Allow to stand for 15 min, add 1500 µL of albumin barbital buffer solution and stir gently until homogeneous. Collect the cells by centrifugation (1000 *g* for 10 min) of the test-tube, remove the supernatant and add approximately 3 mL of albumin barbital buffer solution. Repeat this operation up to 4 times in total, leaving a final volume of 300 µL. Test samples may be stored in sealed test-tubes at 4 °C for not longer than 24 h.

Complement-initiated haemolysis

To measure haemolysis where method A is performed, add 600 µL of albumin barbital buffer solution warmed to 37 °C to the test sample, resuspend the cells carefully by repeated pipetting (not fewer than 5 times) and place the cuvette in the thermostatted cuvette holder of a spectrophotometer. After 2 min, add 200 µL of diluted guinea-pig complement (125-200 CH_{50}/mL), mix thoroughly by pipetting twice and start immediately after the second pipetting the time-dependent recording of absorbance at 541 nm, using albumin barbital buffer solution as the compensation liquid. Stop the measurement if absorbance as a function of time has clearly passed the inflexion point.

To measure haemolysis where method B is performed, add 900 µL of albumin barbital buffer solution warmed to 37 °C to each test-tube and resuspend the cells carefully by repeated pipetting (not fewer than 5 times). The microtitre plate must be prewarmed to 37 °C before starting the test. Transfer 240 µL of each solution into 4 microtitre plate wells then incubate the microplate at 37 °C for 6 min, stirring gently every 10 s. To each microtitre plate well add 60 µL of diluted guinea-pig complement (150 CH_{50}/mL). Mix for 10 s and immediately start recording the absorbance at 541 nm at 37 °C, measuring every 20 s. Stop the measurement if the absorbance as a function of time has clearly passed the inflexion point.

Evaluation

For each cuvette/test-tube/well, determine the slope (S) of the haemolysis curve at the approximate inflexion point by segmenting the steepest section in suitable time intervals (for example, Δt = 1 min), and calculate S between adjacent intersection points, expressed as ΔA per minute. The largest value for S serves as S_{exp}. In addition, determine the absorbance at the start of measurement (A_s) by extrapolating the curve, which is almost linear and parallel to the time axis within the first few minutes. Correct S_{exp} using the expression:

$$S' = \frac{S_{exp}}{A_s}$$

Calculate the arithmetic mean of the values of S' for each preparation (test and reference solution). Calculate the index of Fc function (I_{Fc}) from the expression:

$$I_{Fc} = \frac{100 \times (\overline{S'} - \overline{S'_c})}{\overline{S'_s} - \overline{S'_c}}$$

$\overline{S'}$ = arithmetic mean of the corrected slope for the preparation to be examined;

$\overline{S'_s}$ = arithmetic mean of the corrected slope for the reference preparation;

$\overline{S'_c}$ = arithmetic mean of the corrected slope for the complement control.

Calculate the index of Fc function for the preparation to be examined: the value is not less than that stated in the leaflet accompanying the reference preparation.

C2. Test for Anticomplementary Activity of Immunoglobulin

(Ph. Eur. method 2.6.17)

For the measurement of anticomplementary activity (ACA) of immunoglobulin, a defined amount of test material (10 mg of immunoglobulin) is incubated with a defined amount of guinea-pig complement (20 CH_{50}) and the remaining complement is titrated; the anticomplementary activity is expressed as the percentage consumption of complement relative to the complement control considered as 100 per cent.

The haemolytic unit of complement activity (CH_{50}) is the amount of complement that, in the given reaction conditions, will produce the lysis of 2.5×10^8 out of a total of 5×10^8 optimally sensitised red blood cells.

Magnesium and calcium stock solution Dissolve 1.103 g of *calcium chloride R* and 5.083 g of *magnesium chloride R* in *water R* and dilute to 25 mL with the same solvent.

Barbital buffer stock solution Dissolve 207.5 g of *sodium chloride R* and 25.48 g of *barbital sodium R* in 4000 mL of *water R* and adjust to pH 7.3 using *1 M hydrochloric acid.* Add 12.5 mL of magnesium and calcium stock solution and dilute to 5000 mL with *water R.* Filter through a membrane filter (nominal pore size 0.22 µm). Store at 4 °C in glass containers.

Gelatin solution Dissolve 12.5 g of *gelatin R* in about 800 mL of *water R* and heat to boiling in a water-bath. Cool to 20 °C and dilute to 10 L with *water R.* Filter through a membrane filter (nominal pore size 0.22 µm). Store at 4 °C. Use clear solutions only.

Citrate solution Dissolve 8.0 g of *sodium citrate R,* 4.2 g of *sodium chloride R* and 20.5 g of *glucose R* in 750 mL of *water R.* Adjust to pH 6.1 using a 100 g/L solution of *citric acid monohydrate R* and dilute to 1000 mL with *water R.*

Gelatin barbital buffer solution Add 4 volumes of gelatin solution to 1 volume of barbital buffer stock solution and mix. Adjust to pH 7.3, if necessary, using *1 M sodium hydroxide* or *1 M hydrochloric acid.* Maintain at 4 °C. Prepare fresh solutions daily.

Stabilised sheep blood Collect 1 volume of sheep blood into 1 volume of citrate solution and mix. Store at 4 °C for not less than 7 days and not more than 28 days. (Stabilised sheep blood and sheep red blood cells are available from a number of commercial sources.)

Haemolysin Antiserum against sheep red blood cells prepared in rabbits. (Such antisera are available from a number of commercial sources.)

Guinea-pig complement Prepare a pool of serum from the blood of not fewer than 10 guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store the serum in small amounts below −70 °C.

METHOD

Preparation of standardised 5 per cent sheep red blood cell suspension

Separate sheep red blood cells by centrifuging an appropriate volume of stabilised sheep blood and wash the cells at least 3 times with gelatin barbital buffer solution and prepare a 5 per cent *V/V* suspension in the same solution. Measure the cell density of the suspension as follows: add 0.2 mL to 2.8 mL of *water R* and centrifuge the lysed solution for 5 min at 1000 *g*; the cell density is suitable if the absorbance (*2.2.25*) of the supernatant at 541 nm is 0.62 ± 0.01. Correct the cell density by adding gelatin barbital buffer solution according to the following equation:

$$V_f = \frac{V_i \times A}{0.62}$$

V_f = final adjusted volume;
V_i = the initial volume;
A = absorbance of the original suspension at 541 nm.

The adjusted suspension contains about 1×10^9 cells/mL.

Haemolysin titration

Prepare haemolysin dilutions as shown in Table 2.6.17.-1.

Table 2.6.17.-1

Required dilution of haemolysin	Prepared using		
	Gelatin barbital buffer solution		Haemolysin
	Volume (mL)	Dilution (1/...)	Volume (mL)
7.5	0.65	undiluted	0.1
10	0.90	undiluted	0.1
75	1.80	7.5	0.2
100	1.80	10	0.2
150	1.00	75	1.0
200	1.00	100	1.0
300	1.00	150	1.0
400	1.00	200	1.0
600	1.00	300	1.0
800	1.00	400	1.0
1200	1.00	600	1.0
1600	1.00	800	1.0
2400	1.00	1200	1.0
3200*	1.00	1600	1.0
4800*	1.00	2400	1.0

* discard 1.0 mL of the mixture.

Add 1.0 mL of 5 per cent sheep red blood cell suspension to each tube of the haemolysin dilution series, starting at the 1/75 dilution, and mix. Incubate at 37 °C for 30 min.

Transfer 0.2 mL of each of these incubated mixtures to new tubes and add 1.10 mL of gelatin barbital buffer solution and 0.2 mL of diluted guinea-pig complement (for example, 1/150). Perform this in duplicate.

As the unhaemolysed cell control, prepare 3 tubes with 1.4 mL of gelatin barbital buffer solution and 0.1 mL of 5 per cent sheep red blood cell suspension.

As the fully haemolysed control, prepare 3 tubes with 1.4 mL of *water R* and 0.1 mL of 5 per cent sheep red cell suspension.

Incubate all tubes at 37 °C for 60 min and centrifuge at 1000 *g* for 5 min. Measure the absorbance (*2.2.25*) of the supernatants at 541 nm and calculate the percentage degree of haemolysis in each tube using the following expression:

$$\frac{A_a - A_1}{A_b - A_1} \times 100$$

A_a = absorbance of tubes with haemolysin dilution;
A_b = mean absorbance of the 3 tubes with full haemolysis;
A_1 = mean absorbance of the 3 tubes with no haemolysis.

Plot the percentage degree of haemolysis as the ordinate against the corresponding reciprocal value of the haemolysin dilution as the abscissa on linear graph paper. Determine the optimal dilution of the haemolysin from the graph by inspection. Select a dilution such that further increase in the amount of haemolysin does not cause appreciable change in the degree of haemolysis. This dilution is defined as 1 minimal haemolytic unit (1 MHU) in 1.0 mL. The optimal haemolytic haemolysin dilution for preparation of sensitised sheep red blood cells contains 2 MHU/mL.

The haemolysin titration is not valid unless the maximum degree of haemolysis is 50 per cent to 70 per cent. If the maximum degree of haemolysis is not in this range, repeat the titration with more or less diluted complement solution.

Preparation of optimised sensitised sheep red blood cells (haemolytic system)
Prepare an appropriate volume of diluted haemolysin containing 2 MHU/mL and an equal volume of standardised 5 per cent sheep red blood cell suspension. Add the haemolysin dilution to the standardised cell suspension and mix. Incubate at 37 °C for 15 min, store at 2 °C to 8 °C and use within 6 h.

Titration of complement
Prepare an appropriate dilution of complement (for example 1/250) with gelatin barbital buffer solution and perform the titration in duplicate as shown in Table 2.6.17.-2.

Table 2.6.17.-2

Tube number	Volume of diluted complement (for example 1/250)(mL)	Volume of gelatin barbital buffer solution (mL)
1	0.1	1.2
2	0.2	1.1
3	0.3	1.0
4	0.4	0.9
5	0.5	0.8
6	0.6	0.7
7	0.7	0.6
8	0.8	0.5
9	0.9	0.4
10	1.0	0.3
11	1.1	0.2
12	1.2	0.1
3 tubes as cell control at 0 per cent haemolysis	–	1.3
3 tubes at 100 per cent haemolysis	–	1.3 mL of water

Add 0.2 mL of sensitised sheep red blood cells to each tube, mix well and incubate at 37 °C for 60 min. Cool the tubes in an ice-bath and centrifuge at 1000 *g* for 5 min. Measure the absorbance of the supernatant at 541 nm and calculate the degree of haemolysis (*Y*) using the following expression:

$$\frac{A_c - A_1}{A_b - A_1}$$

A_c = absorbance of tubes 1 to 12;
A_b = mean absorbance of tubes with 100 per cent haemolysis;
A_1 = mean absorbance of cell controls with 0 per cent haemolysis.

Plot $Y/(1-Y)$ as the abscissa against the amount of diluted complement in millilitres as the ordinate on log–log graph paper. Fit the best line to the points and determine the ordinate for the 50 per cent haemolytic complement dose where $Y/(1-Y) = 1.0$. Calculate the activity in haemolytic units (CH_{50}/mL) using the following expression:

$$\frac{C_d}{C_a \times 5}$$

C_d = reciprocal value of the complement dilution;
C_a = volume of diluted complement resulting in 50 per cent haemolysis, in millilitres;
5 = scaling factor to take account of the number of red blood cells.

The test is not valid unless the plot is a straight line between 15 per cent and 85 per cent haemolysis and the slope is 0.15 to 0.40, and preferably 0.18 to 0.30.

Test for anticomplementary activity
Prepare a complement dilution having 100 CH_{50}/mL by diluting titrated guinea-pig complement with gelatin barbital buffer solution. Depending on the immunoglobulin to be examined and based on validation data, a pH adjustment to 7 may be necessary. Prepare incubation mixtures as follows for an immunoglobulin containing 50 mg/mL:

Table 2.6.17.-3

	Immunoglobulin to be examined	Complement control (in duplicate)
Immunoglobulin (50 mg/mL)	0.2 mL	–
Gelatin barbital buffer	0.6 mL	0.8 mL
Complement	0.2 mL	0.2 mL

Carry out the test on the immunoglobulin to be examined and prepare ACA negative and positive controls using *human immunoglobulin for anticomplementary activity BRP*, as indicated in the leaflet accompanying the reference preparation. Higher or lower volumes of sample and of gelatin barbital buffer solution are added if the immunoglobulin concentration varies from 50 mg/mL; for example, 0.47 mL of gelatin barbital buffer solution is added to 0.33 mL of immunoglobulin containing 30 mg/mL to give 0.8 mL. Close the tubes and incubate at 37 °C for 60 min. Add 0.2 mL of each incubation mixture to 9.8 mL of gelatin barbital buffer solution to dilute the complement. Perform complement titrations on each tube as described above to determine the remaining complement activity (Table 2.6.17.-2). Calculate the anticomplementary activity of the preparation to be examined relative to the complement control considered as 100 per cent, using the following expression:

$$\frac{a - b}{a} \times 100$$

a = mean complement activity (CH_{50}/mL) of complement control;
b = complement activity (CH_{50}/mL) of tested sample.

The test is not valid unless:
— the anticomplementary activities found for ACA negative control and ACA positive control are within the limits stated in the leaflet accompanying the reference preparation;
— the mean complement activity of complement control (a) is in the range 80 CH_{50}/mL to 120 CH_{50}/mL.

C3. Assay of Human Anti-D Immunoglobulin
(Ph. Eur. method 2.7.13)

METHOD A
The potency of human anti-D immunoglobulin is determined by comparing the quantity necessary to produce agglutination of D-positive red blood cells with the quantity of a reference preparation, calibrated in International Units, required to produce the same effect.

The International Unit is the activity contained in a stated amount of the International Reference Preparation.
The equivalence in International Units of the International Reference Preparation is stated by the World Health Organization.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

Use pooled D-positive red blood cells, collected not more than 7 days earlier and suitably stored, obtained from not

fewer than 4 group O R_1R_1 donors. To a suitable volume of the cells, previously washed 3 times with a 9 g/L solution of *sodium chloride R*, add an equal volume of *bromelains solution R*, allow to stand at 37 °C for 10 min, centrifuge, remove the supernatant and wash 3 times with a 9 g/L solution of *sodium chloride R*. Suspend 20 volumes of the red blood cells in a mixture of 15 volumes of inert serum, 20 volumes of a 300 g/L solution of *bovine albumin R* and 45 volumes of a 9 g/L solution of *sodium chloride R*. Stand the resulting suspension in iced water, stirring continuously.

Using a calibrated automated dilutor, prepare suitable dilutions of the preparation to be examined and of the reference preparation using as diluent a solution containing 5 g/L of *bovine albumin R* and 9 g/L of *sodium chloride R*.

Use a suitable apparatus for automatic continuous analysis. The following protocol is usually suitable: maintain the temperature in the manifold, except for the incubation coils, at 15.0 °C. Pump into the manifold of the apparatus the red blood cell suspension at a rate of 0.1 mL/min and a 3 g/L solution of *methylcellulose 450 R* at a rate of 0.05 mL/min. Introduce the dilutions of the preparation to be examined and the reference preparation at a rate of 0.1 mL/min for 2 min, followed by the diluent solution at a rate of 0.1 mL/min for 4 min before the next dilution is introduced.

Introduce air at a rate of 0.6 mL/min. Incubate at 37 °C for 18 min and then disperse the rouleaux by introducing at a rate of 1.6 mL/min a 9 g/L solution of *sodium chloride R* containing a suitable wetting agent (for example, *polysorbate 20 R* at a final concentration of 0.2 g/L) to prevent disruption of the bubble pattern. Allow the agglutinates to settle and decant twice, first at 0.4 mL/min and then at 0.6 mL/min. Lyse the unagglutinated red blood cells with a solution containing 5 g/L of *octoxinol 10 R*, 0.2 g/L of *potassium ferricyanide R*, 1 g/L of *sodium hydrogen carbonate R* and 0.05 g/L of *potassium cyanide R* at a rate of 2.5 mL/min. A 10-minute delay coil is introduced to allow for conversion of the haemoglobin. Continuously record the absorbance (*2.2.25*) of the haemolysate at a wavelength between 540 nm and 550 nm. Determine the range of antibody concentrations over which there is a linear relationship between the concentration and the resultant change in absorbance (ΔA). From the results, prepare a standard curve and use the linear portion of the curve to determine the activity of the preparation to be examined.

Calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

METHOD B

The potency of human anti-D immunoglobulin is determined by competitive enzyme-linked immunoassay on erythrocyte-coated microtitre plates. The method is based on the competitive binding between a polyclonal anti-D immunoglobulin preparation and a biotinylated monoclonal anti-D antibody directed against a D-antigen-specific epitope. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organization.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

MATERIALS

Reagents not specified are of analytical grade.

PBS (Phosphate-buffered saline) Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R*, 0.2 g of *potassium dihydrogen phosphate R* and 0.2 g of *sodium azide R* in *water R* and dilute to 1000 mL with the same solvent.

TBS (Tris-buffered saline) Dissolve 8.0 g of *sodium chloride R* and 0.6 g of *tris(hydroxymethyl)aminomethane R* in *water R*. Adjust to pH 7.2 with *1 M hydrochloric acid* and dilute to 1000 mL with *water R*.

Papain solution Prepare a solution by stirring 1 g of *papain R* at 37 °C for 30 min in 10 mL of *0.067 M phosphate buffer solution pH 5.4 R*, centrifuge at 10 000 *g* for 5 min and filter through a membrane filter (nominal pore size 0.22 µm). To activate, combine 1 mL of the filtrate with 1 mL of a 48.44 g/L solution of *L-cysteine R* and 1 mL of a 3.72 g/L solution of *sodium edetate R* and dilute to 10 mL with *0.067 M phosphate buffer solution pH 5.4 R*. Freeze in aliquots at −20 °C or below.

Red blood cells Use pooled D-positive red blood cells obtained from not fewer than 3 group O R_2R_2 donors. Wash the cells 4 times with PBS. Centrifuge the cells at 1800 *g* for 5 min, mix a suitable volume of prewarmed packed cells with a suitable volume of prewarmed papain solution (2 volumes to 1 volume has been found suitable) and incubate at 37 °C for 10 min. Wash the cells 4 times with PBS. Store at 4 °C in an appropriate stabiliser for up to 1 week.

Biotinylated Brad-5 Use according to instructions.

Alkaline phosphatase-conjugated avidin/streptavidin reagent Preferably modified to combine high specific activity with low non-specific binding. Use according to instructions.

Substrate solution Use *para*-nitrophenyl phosphate according to instructions.

Cell fixation buffer Dissolve 18.02 g of *glucose R*, 4.09 g of *sodium chloride R*, 1.24 g of *boric acid R*, 10.29 g of *sodium citrate R* and 0.74 g of *sodium edetate R* in *water R*. Adjust to pH 7.2-7.3 using *1 M sodium hydroxide* or *1 M hydrochloric acid*, and dilute to 1000 mL with *water R*. Use directly from storage at 4 °C.

Glutaraldehyde solution Immediately before use, add 750 µL of a 250 g/L solution of *glutaraldehyde R* to 50 mL of cold PBS.

Microtitre plates Plates to be coated with red blood cells are flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity. Plates used to prepare immunoglobulin dilutions are U- or V-bottomed polystyrene or poly(vinyl chloride) plates.

METHOD

Prepare a 0.1 per cent *V/V* suspension of papain-treated red blood cells in cold cell-fixation buffer. Pipette 50 µL into each well of the flat-bottomed microtitre plate.

Centrifuge the plate at 350 *g* for 3 min, preferably at 4 °C. Without removing the supernatant, gently add 100 µL of glutaraldehyde solution to each well and leave for 10 min.

Drain the wells by quickly inverting the plate and wash 3 times with 250-300 µL of PBS. This may be done manually or using a suitable automated plate washer. Either carry out the assay as described below, or store the plate at 4 °C after draining off the PBS and adding 100 µL of cell-fixation buffer per well and sealing with plastic film. Plates can be stored at 4 °C for up to 1 month.

Test solutions For freeze-dried preparations, reconstitute as stated on the label. Prepare 4 independent replicates of 5 serial 2-fold dilutions starting with 30 IU/mL in PBS containing 10 g/L of *bovine albumin R*. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Reference solutions Reconstitute the reference preparation according to instructions. Prepare 4 independent replicates of 5 serial 2-fold dilutions starting with 30 IU/mL in PBS containing 10 g/L of *bovine albumin R*.

Using U- or V-bottomed microtitre plates, add 35 µL of each of the dilutions of the test solution or reference solution to each of a series of wells. To each well add 35 µL of biotinylated Brad-5 at 250 ng/mL.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel. Add 250 µL of PBS containing 20 g/L of *bovine albumin R* and leave at room temperature for 30 min.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel and transfer 50 µL from each of the dilutions of the test solution or reference solution containing biotinylated Brad-5 into the wells. Use 50 µL of PBS containing 10 g/L of *bovine albumin R* as negative control. Seal the plate with plastic film and incubate at room temperature for 1 h.

Remove the liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 µL of TBS.

Dilute the alkaline phosphatase-conjugated avidin/streptavidin reagent in TBS containing 10 g/L of *bovine albumin R* and add 50 µL to each well. Incubate for 30 min at room temperature.

Remove the liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 µL of TBS.

Add 100 µL of substrate solution to each of the wells and incubate at room temperature for 10 min in the dark. To stop the reaction, add 50 µL of *3 M sodium hydroxide* to each of the wells.

Measure the absorbances at 405 nm and substract the negative control reading. Use the absorbance values in the linear range of the titration curve to estimate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

METHOD C

The potency of human anti-D immunoglobulin is determined by flow cytometry in a microtitre plate format. The method is based on the specific binding between anti-D immunoglobulin and D-positive red blood cells. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference preparation is stated by the World Health Organization.

Human anti-D immunoglobulin BRP is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

MATERIALS

Reagents not specified are of analytical grade.

PBS Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *disodium hydrogen phosphate dodecahydrate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 mL with the same solvent.

PBS-BSA solution PBS containing 10.0 g/L of *bovine albumin R*.

Red blood cells Use D-positive red blood cells obtained from a group O R_1R_1 donor within 2 weeks of collection. Store if necessary in an appropriate stabiliser at 4 °C. Wash the cells at least twice with PBS-BSA solution and prepare a suspension containing 1×10^4 cells per microlitre but not more than 5×10^4 cells per microlitre in PBS-BSA solution.

Use D-negative red blood cells obtained from a group O rr donor and prepared similarly.

Secondary antibody Use a suitable fluorescent dye-conjugated anti-IgG antibody fragment specific for human IgG or parts of it. Store and use according to the manufacturer's instructions.

Microtitres plates Use flat-bottomed plates without surface treatment for enzyme immunoassays.

METHOD

Test solutions For freeze-dried preparations, reconstitute as stated on the label. Prepare at least 3 independent replicates of at least 3 serial 1.5- or 2-fold dilutions starting with a concentration in the range of 1.2-0.15 IU/mL using PBS/BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Reference solutions Reconstitute the reference preparation according to instructions. Prepare at least 3 independent replicates of at least 3 serial 1.5- or 2-fold dilutions starting with a concentration in the range of 1.2-0.15 IU/mL using PBS-BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Distribute 50 µL of the D-positive red blood cells into each well of a microtitre plate. Add 50 µL of each of the dilutions of the test solution or reference solution to each of a series of wells. Use 50 µL of PBS-BSA solution as negative control. Distribute 50 µL of the D-negative red blood cells into 4 wells of the same microtitre plate and add 50 µL of the lowest dilution of the test preparation. To monitor spurious reactions, distribute 50 µL of the D-positive red blood cells into 4 wells of the same microtitre plate and add 50 µL of PBS-BSA solution. Seal with plastic film and incubate at 37 °C for 40 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µL of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and add 50 µL of the secondary antibody diluted with PBS-BSA solution to a suitable protein concentration. Seal with plastic film and incubate, protected from light, at room temperature for 20 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µL of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, resuspend the cells into 200-250 µL of PBS. Transfer the cell suspension into a tube suitable for the flow-cytometry equipment available and further dilute by adding PBS to allow a suitable flow rate.

Proceed immediately with measurement of the median fluorescence intensity in a flow cytometer. Record at least 10 000 events without gating but excluding debris.

Use the median fluorescence intensity in the linear range of the dose-response curve to estimate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

C4. Test for Anti-D Antibodies in Human Immunoglobulin

(Ph. Eur. method 2.6.26)

MATERIALS

Phosphate-buffered saline (PBS) Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 mL with the same solvent. If the solution has to be kept for several days, 0.2 g of *sodium azide R* may be added in order to avoid microbial contamination.

PBS-BSA solution PBS containing 2 g/L of *bovine albumin R* (Cohn Fraction V, for ELISA). Store the solution at 2-8 °C but allow it to reach 19-25 °C before use.

Papain solution Use serological-grade papain from a commercial source, the activity of which has been validated.

Red blood cells Use pooled D-positive red blood cells from not fewer than 3 donors, preferably of group OR_2R_2. D-positive red blood cells may also be obtained from OR_1R_1 or OR_1R_2 donors. Mixing phenotypes has not been tested and is therefore not recommended.

Use pooled D-negative red blood cells, preferably from 3 donors of group Orr. When only 1 donor of group Orr is available, D-negative red blood cells from only 1 donor may be used.

Wash the cells 4 times with PBS or until the supernatant is clear. Each wash consists of suspending the cells in a minimum of 2 volumes of PBS, centrifuging the cells at 1800 *g* for 5 min to pack, and discarding the supernatant. Treat the packed cells with papain solution according to the manufacturer's instructions and wash the cells 4 times with PBS.

Red blood cells may be stored for not more than 1 week in a preservative solution at 2-8 °C. A preparation of the following composition is appropriate:

Trisodium citrate	8 g/L
D-glucose	20 g/L
Citric acid	0.5 g/L
Sodium chloride	4.2 g/L
Inosine	0.938 g/L
Adenosine triphosphate (ATP)	0.4 g/L
Chloramphenicol	0.34 g/L
Neomycin sulfate	0.1 g/L

If using stored cells, wash the cells at least twice in PBS or until the supernatant is clear before proceeding.

Microtitre plates Use V-bottomed rigid microtitre plates.

Reference standards *Immunoglobulin (anti-D antibodies test) BRP* and *Immunoglobulin (anti-D antibodies test negative control) BRP* are suitable for use as the positive control and negative control, respectively.

METHOD

The test described in this chapter is performed at room temperature on the positive control solutions, the negative control solutions and the test solutions at the same time and under identical conditions.

Reference solutions Reconstitute the positive control and the negative control according to the instructions. The immunoglobulin G (IgG) concentration is 50 g/L in each of the reconstituted preparations. Make a 2-fold dilution of each reconstituted preparation with PBS-BSA solution to obtain solutions containing IgG at 25 g/L. Prepare 7 further serial 2-fold dilutions of each preparation using PBS-BSA solution to extend the dilution range to 1/256 (0.195 g/L IgG). Add 20 µL of each dilution of each preparation in duplicate to the microtitre plate.

Test solutions Dilute the preparation to be examined with PBS-BSA solution to obtain a starting IgG concentration of 25 g/L. For 50 g/L preparations, this is a 2-fold dilution; adjust the dilution factor accordingly for preparations with an IgG concentration other than 50 g/L to obtain a starting concentration of 25 g/L for testing. This 25 g/L solution is assigned a nominal 2-fold dilution factor for comparison with the reference solutions, even if this does not reflect the true dilution factor used to achieve 25 g/L. Prepare 7 further serial 2-fold dilutions of the preparation using PBS-BSA solution to extend the nominal dilution range to 1/256 (0.195 g/L IgG) for comparison with the reference preparations over the same IgG concentration range. Add 20 µL of each dilution in duplicate to the microtitre plate.

Prepare 3 per cent *V/V* suspensions of papain-treated D-positive (preferably OR_2R_2, but OR_1R_1 or OR_1R_2 may also be used) and D-negative (Orr) red blood cells in PBS-BSA solution. Add 20 µL of D-positive red blood cells to 1 dilution series of each of the preparation to be examined, the positive control and the negative control, and 20 µL of D-negative red blood cells to the other dilution series. Mix by shaking the plate on a shaker for 10 s (or until the cells are resuspended).

Centrifuge the plate at 80 *g* at room temperature for 1 min to pack the cells. Place the plate at an angle of approximately 70°. Read after 4-5 min or when the negative controls (D-negative red blood cells and negative control solution) have streamed. A cell button at the bottom of the well indicates a positive result. A stream of cells represents a negative result.

Record the endpoint titre as the reciprocal of the highest dilution that gives rise to a positive result.

The positive control has a nominal titre of 8 and the negative controls (D-negative red blood cells and negative control solution) must not show agglutination at the starting dilution of 1 in 2. Users must validate their own test conditions, and investigate their assay conditions and reagents in the event of results being significantly different from those expected. Failure to obtain negative reactions with the negative controls may indicate that, for example, insufficient time has elapsed for the cells to stream, or that reagents have been used directly from cold storage.

The titre of the preparation to be examined must not be greater than the titre of the positive control when both preparations are titrated from 25 g/L.

C5. Anti-A and Anti-B Haemagglutinins

(Ph. Eur. method 2.6.20)

METHOD A: INDIRECT METHOD

Prepare in duplicate serial dilutions of the preparation to be examined in a 9 g/L solution of *sodium chloride R*. To each dilution of 1 series add an equal volume of a 5 per cent *V/V* suspension of group A_1 red blood cells previously washed 3 times with the sodium chloride solution. To each dilution of the other series add an equal volume of a 5 per cent *V/V* suspension of group B red blood cells previously washed 3 times with the sodium chloride solution. Incubate the suspensions at 37 °C for 30 min then wash the cells 3 times with the sodium chloride solution. Leave the cells in contact with a polyvalent anti-human globulin reagent for 30 min. Without centrifuging, examine each suspension for agglutination under a microscope.

METHOD B: DIRECT METHOD

MATERIALS

Phosphate-buffered saline (PBS) Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 mL with the same solvent. If the solution has to be kept for several days, 0.2 g of *sodium azide R* may be added in order to avoid microbial contamination.

PBS-BSA solution PBS containing 2 g/L of *bovine albumin R* (Cohn Fraction V, for ELISA). Store the solution at 2-8 °C but allow it to reach 19-25 °C before use.

Papain solution Use serological-grade papain from a commercial source, the activity of which has been validated.

Red blood cells Use pooled D-negative A_1 (A_1rr), D-negative B (Brr) and D-negative O (Orr) red blood cells from preferably 3 donors. When *Immunoglobulin for anti-A and anti-B antibodies limit test BRP* is used, 3 donors are to be used. A_2 red blood cells are not recommended as they give weaker reactions.

Wash the cells 4 times with PBS or until the supernatant is clear. Each wash consists of suspending the cells in a minimum of 2 volumes of PBS, centrifuging the cells at 1800 *g* for 5 min to pack, and discarding the supernatant. Treat the packed cells with papain solution according to the manufacturer's instructions and wash the cells 4 times with PBS.

Red blood cells may be stored for not more than 1 week in a preservative solution at 2-8 °C. A preparation of the following composition is appropriate:

Trisodium citrate	8 g/L
D-glucose	20 g/L
Citric acid	0.5 g/L
Sodium chloride	4.2 g/L
Inosine	0.938 g/L
Adenosine triphosphate (ATP)	0.4 g/L
Chloramphenicol	0.34 g/L
Neomycin sulfate	0.1 g/L

If using stored cells, wash the cells at least twice in PBS or until the supernatant is clear before proceeding.

Microtitre plates Use V-bottomed rigid microtitre plates.

Reference standards *Immunoglobulin (anti-A, anti-B antibodies test positive control) BRP* and *Immunoglobulin (anti-A, anti-B antibodies test negative control) BRP* are suitable for use as the positive control and negative control, respectively, and should be used as guides for operators establishing and performing the direct method for anti-A and anti-B haemagglutinins.

Immunoglobulin for anti-A and anti-B antibodies limit test BRP defines the recommended maximum limits permissible for batches of human immunoglobulin and must be used only for comparison with batches of human immunoglobulin that have higher titres than the positive control.

METHOD

The test described in this chapter is performed at room temperature on the positive control solutions, the negative control solutions and the test solutions at the same time and under identical conditions. Whenever necessary, a further test is performed with *Immunoglobulin for anti-A and anti-B antibodies limit test BRP*.

Reference solutions Reconstitute the positive control and the negative control according to the instructions.
The immunoglobulin G (IgG) concentration is 50 g/L in each of the reconstituted preparations. Make a 2-fold dilution of each reconstituted preparation with PBS-BSA solution to obtain solutions containing IgG at 25 g/L. Prepare 7 further serial 2-fold dilutions of each preparation using PBS-BSA solution to extend the dilution range to 1/256 (0.195 g/L IgG). Add 20 µL of each dilution of each preparation in triplicate to the microtitre plate.

Test solutions Dilute the preparation to be examined with PBS-BSA solution to obtain a starting IgG concentration of 25 g/L. For 50 g/L preparations, this is a 2-fold dilution; adjust the dilution factor accordingly for preparations with an IgG concentration other than 50 g/L to obtain a starting concentration of 25 g/L for testing. This 25 g/L solution is assigned a nominal 2-fold dilution factor for comparison with the reference solutions, even if this does not reflect the true dilution factor used to achieve 25 g/L. Prepare 7 further serial 2-fold dilutions of the preparation using PBS-BSA solution to extend the nominal dilution range to 1/256 (0.195 g/L IgG) for comparison with the reference preparations over the same IgG concentration range. Add 20 µL of each dilution in triplicate to the microtitre plate.

For preparations with an IgG concentration lower than 25 g/L, dilute to a starting concentration corresponding to the nearest lower concentration of the reference solutions. This solution is assigned the same nominal dilution factor as the corresponding reference solution having the same IgG concentration. Proceed with the preparation of the appropriate 2-fold dilution series as described above.

Prepare 3 per cent *V/V* suspensions of papain-treated D-negative A_1, B and O red blood cells in PBS/BSA solution. Add 20 µL of D-negative A_1, B and O red blood cells respectively to the 1st, the 2nd and the 3rd dilution series of each of the preparation to be examined, the positive control and the negative control. Mix by shaking the plate on a shaker for 10 s (or until the cells are resuspended).

Centrifuge the plate at 80 *g* at room temperature for 1 min to pack the cells. Place the plate at an angle of approximately 70°. Read after 4-5 min or when the negative controls (D-negative O red blood cells and negative control solution) have streamed. A cell button at the bottom of the well indicates a positive result. A stream of cells represents a negative result.

Record the endpoint titre as the reciprocal of the highest dilution that gives rise to a positive result.

The positive control has nominal anti-A and anti-B titres of 32 (range 32-64 for anti-A; range 16-32 for anti-B) and the negative controls (D-negative O red blood cells and negative control solution) must not show agglutination at the starting dilution of 1 in 2. Users must validate their own test conditions, and investigate their assay conditions and reagents in the event of results being significantly different from those expected. Failure to obtain negative reactions with the negative controls may indicate that, for example, insufficient time has elapsed for the cells to stream, or that reagents have been used directly from cold storage.

If the nominal anti-A or anti-B titre of the preparation to be examined is greater than the titre of the positive control, the test preparation is to be compared with *Immunoglobulin for anti-A and anti-B antibodies limit test BRP*.

The maximum allowable titre is 64.

Other blood-related components

D1. Assay of Human α-1-proteinase Inhibitor

(Ph. Eur. method 2.7.32)

Human α-1-proteinase inhibitor (also known as α-1-antitrypsin or α-1-antiproteinase) content is determined by comparing the ability of the preparation to be examined to inactivate the serine protease elastase (porcine pancreatic elastase or human neutrophil elastase) with the same ability of a reference standard of human α-1-proteinase inhibitor calibrated in milligrams of active (functional) α-1-proteinase inhibitor. Varying quantities of the preparation to be examined are mixed with a given quantity of elastase and the remaining elastase activity is determined using a suitable chromogenic substrate. The method described below is given as an example.

REAGENTS

Tris-albumin buffer solution Dissolve 24.23 g of *trometamol R* in *water R*, adjust to pH 8.0 ± 0.3 using *hydrochloric acid R1* and dilute to 1000 mL with *water R*. To 100 mL of this solution add 0.5 mL of a 20 per cent solution of *human albumin R* or *bovine albumin R*.

Buffer solution containing human or bovine albumin must be prepared fresh on the day of its use; otherwise, it can be conserved by sterile filtration (0.2 µm) and stored at 2-8 °C for up to 2 weeks.

METHOD

Prepare 2 series of 4 or 5 dilutions in an appropriate human α-1-proteinase inhibitor concentration range, for both the preparation to be examined and the reference standard, using the tris-albumin buffer solution.

Transfer 50 µL of the reference solution dilutions into the wells of a microtitre plate and to each well, add 150 µL of a porcine pancreatic elastase solution diluted to an appropriate concentration with the tris-albumin buffer solution. Incubate for a defined period of time, 3-10 min, at room temperature. Since the activity of the solutions of the different porcine pancreatic elastases may vary, the concentration of elastase can be adjusted by evaluation of blank values containing elastase but no human α-1-proteinase inhibitor, to exhibit a suitable change of absorbance at 405 nm under the actual assay conditions.

Add to each well 100 µL of a solution of chromogenic substrate *N*-succinyl-tri-L-alanyl 4-p-nitroanilide (Suc-Ala-Ala-Ala-pNA), reconstituted in *dimethyl sulfoxide R* to give a solution containing 4.5 mg/mL, then further diluted with the tris-albumin buffer solution to a concentration of 0.45 mg/mL. Immediately start measurement of the change in absorbance (*2.2.25*) at 405 nm using a microtitre plate reader, continuing the measurement for at least 5 min. Calculate the rate of change of absorbance (ΔA/min). Alternatively, an end-point assay may be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm. If the assay is performed in test tubes using spectrophotometers for monitoring the change in absorbance at 405 nm, the volumes of reagent solutions are changed proportionally.

The rate of change of absorbance (ΔA/min) is inversely proportional to human α-1-proteinase inhibitor activity.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (*5.3*).

D2. Assay of Human C1-Esterase Inhibitor

(Ph. Eur. method 2.7.34)

The human C1-esterase inhibitor content of the preparation to be examined is determined by comparing its ability to inhibit C1-esterase with that of a reference preparation calibrated in International Units. The International Unit is the activity of a stated amount of the International Standard for human plasma-derived C1-esterase inhibitor concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organization. Varying quantities of the preparation to be examined are mixed with an excess of C1-esterase and the remaining C1-esterase activity is determined using a suitable chromogenic substrate.

Individual reagents may be obtained separately or in commercial kits. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example of a microtitre-plate kinetic method.

Reconstitute the preparation as stated on the label. Prepare an appropriate series of at least 3 dilutions, from 1 IU/mL of C1-esterase inhibitor, for both the preparation to be examined and the reference preparation, using a suitable pH 7.4 buffer solution containing 9 g/L of *sodium chloride R* and either 10 g/L of *human albumin R* or 10 g/L of *bovine albumin R*. Warm all solutions to 37 °C. Place a suitable quantity of 1 of the dilutions of the reference preparation or of the preparation to be examined in microtitre plate wells and incubate at 37 °C. To each well add a suitable quantity of C1-esterase solution and incubate at 37 °C for 5 min. Add an appropriate quantity of a suitable specific chromogenic substrate such as methoxycarbonyl-L-lysyl(ε-benzyloxycarbonyl)-glycyl-L-arginine-4-nitroanilide. Read the rate of increase of absorbance (Δ*A*/min) at 405 nm. A positive control, using the pH 7.4 buffer solution instead of the C1-esterase inhibitor, is included. For preparations that may exhibit proteolytic activity, a test is carried out on a suitable blank composed of the preparation to be examined, the pH 7.4 buffer solution and the chromogenic substrate.

Calculate the C1-esterase inhibitor content using the usual statistical methods, for example slope ratio (*5.3*).

K. Immunological Products

1. Assay of Diphtheria Vaccine (Adsorbed)

(Ph. Eur. method 2.7.6. An alternative in vivo method (Method B) in which the potency is determined by comparing the dose necessary to protect guinea-pigs against the lethal effect of a subcutaneous injection of diphtheria toxin with the dose of a reference preparation calibrated in International Units necessary to give the same protection is also described in the European Pharmacopoeia.)

The potency of diphtheria vaccine is determined by administration of the vaccine to guinea-pigs followed either by challenge with diphtheria toxin (method A or B) or by determination of the titre of antibodies against diphtheria toxin or toxoid in the serum of guinea-pigs (method C). In both cases, the potency of the vaccine is calculated by comparison with a reference preparation, calibrated in International Units.

The International Unit is the activity contained in a stated amount of the International Standard, which consists of a

quantity of diphtheria toxoid adsorbed on aluminium hydroxide. The equivalence in International Units of the International Standard is stated by the World Health Organization (WHO).

Diphtheria vaccine (adsorbed) BRP is suitable for use as a reference preparation.

The method chosen for the assay of diphtheria vaccine (adsorbed) depends on the intended purpose. Method A or B is used:

1. during development of a vaccine, to assay batches produced to validate the production;

2. wherever revalidation is needed following a significant change in the manufacturing process.

Method A or B may also be used for the routine assay of batches of vaccine, but in the interests of animal welfare, method C is used wherever possible.

Method C may be used, except as specified under 1 and 2 above, after verification of the suitability of the method for the product. For this purpose, a suitable number of batches (usually 3) are assayed by method C and method A or B. Where different vaccines (monovalent or combinations) are prepared from diphtheria toxoid of the same origin, and with comparable levels (expressed in Lf/mL) of the same diphtheria toxoid, suitability demonstrated for the combination with the highest number of components can be assumed to be valid for combinations with fewer components and for monovalent vaccines. Any combinations containing a whole-cell pertussis component or containing haemophilus type b conjugate vaccine with diphtheria toxoid or CRM 197 diphtheria protein as carrier in the same vial must always be assessed separately.

For combinations containing diphtheria and tetanus components, the serological assay (method C) can be performed with the same group of animals used for the serological assay of the tetanus vaccine (adsorbed) (*2.7.8*) when the common immunisation conditions for the diphtheria and the tetanus components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine.

The design of the assays described below uses multiple dilutions for the test and reference preparations. Once the analyst has sufficient experience with this method for a given vaccine, it is possible to apply a simplified model such as a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required, but does not give information on linearity, parallelism and the dose-response curve.
The simplified model allows for a considerable reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes.

Where a single-dilution assay is used, production and test consistency over time are monitored via suitable indicators and by carrying out a full multiple-dilution assay periodically, for example every 2 years. For serological assays, suitable indicators to monitor test consistency are:

- the mean and standard deviation of relative antitoxin titres or scores of the serum samples obtained after administration of a fixed dose of the vaccine reference preparation;
- the antitoxin titres or scores of run controls (positive and negative serum samples);
- the ratio of antitoxin titres or scores for the positive serum control to the serum samples corresponding to the reference vaccine.

METHOD A: INTRADERMAL CHALLENGE TEST IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy, white guinea-pigs from the same stock and of a size suitable for the prescribed number of challenge sites, the difference in body mass between the heaviest and the lightest animal being not greater than 100 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 5 guinea-pigs as unvaccinated controls.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of diphtheria toxin containing 67 to 133 lf/100 in 1 Lf and 25 000 to 50 000 minimal reacting doses for guinea-pig skin in 1 Lf. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the activity for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent to obtain a challenge toxin solution containing about 0.0512 Lf in 0.2 mL. Prepare from this a further series of 5 four-fold dilutions containing about 0.0128, 0.0032, 0.0008, 0.0002 and 0.00005 Lf in 0.2 mL.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/L solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 mL per guinea-pig, will result in an intradermal score of approximately 3 when the animals are challenged.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 mL of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, shave both flanks of each guinea-pig and inject 0.2 mL of each of the 6 toxin dilutions intradermally into 6 separate sites on each of the vaccinated guinea-pigs in such a way as to minimise interference between adjacent sites.

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, inject the unvaccinated control animals with dilutions containing 80, 40, 20, 10 and 5 × 10^{-6} Lf of the challenge toxin.

READING AND INTERPRETATION OF RESULTS

Examine all injection sites 48 h after injection of the challenge toxin and record the incidence of specific diphtheria erythema. Record also the number of sites free from such reactions as the intra-dermal challenge score. Tabulate the intradermal challenge scores for all the animals receiving the same dilution of vaccine and use those data with a suitable transformation, such as $(score)^2$ or $\arcsin((score/6)^2)$, to obtain an estimate of the relative

potency for each of the test preparations by parallel-line quantitative analysis.

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

— for both the vaccine to be examined and the reference preparation, the mean score obtained at the lowest dose level is less than 3 and the mean score at the highest dose level is more than 3;

— where applicable, the toxin dilution that contains 40×10^{-6} Lf gives a positive erythema in at least 80 per cent of the control guinea-pigs and the dilution containing 20×10^{-6} Lf gives a positive erythema in less than 80 per cent of the guinea-pigs (if these criteria are not met a different toxin has to be selected);

— the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;

— the statistical analysis shows no deviation from linearity and parallelism.

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. Use a further group of non-vaccinated guinea-pigs of the same origin to provide a negative serum control. If test consistency has been demonstrated, a reference negative serum control may be used.

REFERENCE PREPARATION

Use a suitable reference preparation such as *diphtheria vaccine (adsorbed) BRP* or a batch of vaccine shown to be effective in clinical studies, or a batch representative thereof, and which has been calibrated in International Units with reference to *diphtheria vaccine (adsorbed) BRP* or the International Standard for diphtheria toxoid (adsorbed).

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/L solution of *sodium chloride R* as diluent, prepare serial dilutions of the vaccine to be examined and the reference preparation; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range of, for example, 0.5-16 IU/mL for the reference vaccine and within the range of, for example, 1:2 to 1:125 for the vaccine to be examined. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

IMMUNISATION

Inject subcutaneously to each guinea-pig 1.0 mL of the dilution allocated to its group.

BLOOD SAMPLING

35-42 days after immunisation, take a blood sample from each vaccinated and control guinea-pig using a suitable method.

PREPARATION OF SERUM SAMPLES

Avoid frequent freezing and thawing of serum samples. To avoid microbial contamination, it is preferable to carry out manipulations in a laminar-flow cabinet.

DETERMINATION OF ANTIBODY TITRE

Determine the relative antibody titre or score of each serum sample by a suitable immunochemical method (*2.7.1*). The methods shown below (enzyme-linked immunosorbent assay (ELISA) and Vero cell assay) have been found to be suitable.

CALCULATION OF POTENCY

Calculate the potency of the vaccine to be examined in International Units relative to the reference preparation, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

— the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;

— the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

The following section is published for information.

ASSAY OF DIPHTHERIA VACCINE (ADSORBED): GUIDELINES

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

PREPARATION OF SERUM SAMPLES

For the preparation of serum samples, the following technique has been found to be suitable. Invert the tubes containing blood samples 6 times and allow to stand at 37 °C for 2 h, then at 4 °C for 2 h. Centrifuge at room temperature at 800 *g* for 20 min. Transfer the serum to sterile tubes and store at a temperature below −20 °C. At least a 40 per cent yield of serum is obtained by this procedure.

DETERMINATION OF ANTIBODY TITRE

The ELISA and Vero cell assays shown below are given as examples of immunochemical methods that have been found to be suitable for the determination of antibody titre.

Determination of antibody titre in guinea-pig serum by enzyme-linked immunosorbent assay (ELISA)

Dilutions of test and reference sera are made on ELISA plates coated with diphtheria toxoid. A positive guinea-pig serum control and a negative guinea-pig serum control are included on each plate to monitor the assay performance. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig-IgG is added, followed by a peroxidase substrate. Optical density is measured and the relative antibody titre is calculated using the usual statistical methods (for example, *5.3*).

Reagents and equipment

— *ELISA plates*: 96 wells, columns 1-12, rows A-H.

— *Diphtheria guinea-pig antiserum (for vaccines-human use)* (positive control serum), obtained by immunisation of guinea-pigs using *diphtheria vaccine (adsorbed) BRP*.

— *Peroxidase conjugate*. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.

— *Diphtheria toxoid*.

— *Carbonate coating buffer pH 9.6.* Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 mL of *water R.* Distribute into 150 mL bottles and sterilise by autoclaving at 121 °C for 15 min.
— *Phosphate-buffered saline pH 7.4 (PBS).* Dissolve with stirring 80.0 g of *sodium chloride R,* 2.0 g of *potassium dihydrogen phosphate R,* 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 mL of *water R.* Store at room temperature to prevent crystallisation. Dilute to 10 times its volume with *water R* before use.
— *Citric acid solution.* Dissolve 10.51 g of *citric acid monohydrate R* in 1000 mL of *water R* and adjust the solution to pH 4.0 with a 400 g/L solution of *sodium hydroxide R.*
— *Washing buffer.* PBS containing 0.5 g/L of *polysorbate 20 R.*
— *Diluent blocking buffer.* PBS containing 0.5 g/L of *polysorbate 20 R* and 25 g/L of dried skimmed milk.
— *Peroxidase substrate.* Shortly before use, dissolve 10 mg of *diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonate) R* (ABTS) in 20 mL of citric acid solution. Immediately before use add 5 µL of *strong hydrogen peroxide solution R.*

Method

The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are for negative control serum and wells 2A-H and 12A-H are for positive control serum for assay monitoring. Wells 3-11A-H are for test samples.

Coat each well of the ELISA plates with 100 µL of diphtheria toxoid solution (0.5 Lf/mL in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with washing buffer. Block the plates by addition of 100 µL of diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing buffer. Place 100 µL of diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of negative control serum, positive control serum (from about 0.01 IU/mL) and test sera. Allocate the negative control serum to column 1, positive control serum to columns 2 and 12 and test sera to columns 3-11 and add 100 µL of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make twofold serial dilutions from row B, down the plate to row H, by transferring 100 µL from one well to the next well. Discard 100 µL from the last row so that all wells contain 100 µL. Incubate at 37 °C for 2 h. Wash thoroughly with washing buffer. Prepare a suitable dilution (a 2000-fold dilution has been found to be suitable) of peroxidase conjugate in diluent block buffer and add 100 µL to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing buffer. Add 100 µL of peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as addition of substrate was made.

Determination of antibody titre in guinea-pig serum by Vero cell assay

The method used relies either on metabolic inhibition (method 1) or on cytotoxicity (method 2) as the end point, and on either microscopic (cell morphology) or visual (colour) inspection of the cells.

The limit of detection is specific for each antitoxin and is usually between 0.015 IU/mL (method 1) and 0.05 IU/mL (method 2).

The endpoint is taken as the highest serum dilution protecting cells from the diphtheria toxin effect.
The antitoxin activity is calculated with respect to guinea-pig or WHO reference standard, and expressed in International Units per millilitre.

Reagents and equipment

— *Flat-bottomed tissue culture plates*: 96 wells, columns 1-12, rows A-H.
— *75 cm^2 tissue culture flasks.*
— *Diphtheria toxin.*
— *Diphtheria guinea-pig antiserum (for vaccines-human use)* (positive control serum), obtained by immunisation of guinea-pigs with *diphtheria vaccine (adsorbed) BRP.*
— *Vero cells* (African Green Monkey kidney cells). Cell passages from P2 to P15 are suitable for use.

Method 1 The diphtheria toxin causes a cytopathogenic effect on Vero cells leading to cellular lysis. Antibodies directed against diphtheria toxin may inhibit this cytopathogenic effect. Consequently, the potency of a diphtheria vaccine may be indirectly determined with the help of this cell culture system if different serum dilutions from immunised animals are cultured with a constant toxin concentration. In the Vero cell assay, yellow colour indicates viable cells, red colour dead cells. When only part of the cells are dead, the colour may be orange.

Reagents and equipment

— *Modified MEM.* Minimum Essential Medium (MEM) with Earle's Salts, without L-glutamine and sodium bicarbonate.
— *Modified medium 199.* Medium 199, with Hanks' Solution and L-glutamine, without sodium bicarbonate.
— *Foetal bovine serum.*
— *Sodium bicarbonate 7.5 per cent solution.*
— *Trypsin solution:* trypsin 2.5 per cent solution.
— *EDTA solution:* EDTA 0.02 per cent (Versene 1:5000) solution.
— *Modified D-PBS.* Dulbecco's phosphate buffered saline (D-PBS), without calcium, or magnesium.
— *L-glutamine 200mM solution.*
— *Penicillin/streptomycin solution.*
— *Primary culture medium.* To 50 mL of modified MEM add 440 mL of *water R,* 5 mL of L-glutamine 200 mM solution, and 10 mL of sodium bicarbonate 7.5 per cent solution. To 25 mL of this medium add 1.25 mL of foetal bovine serum.
— *Maintenance culture medium.* Similar to the primary culture medium except that 0.5 mL instead of 1.25 mL of foetal bovine serum is added to 20 mL of the enriched MEM medium.
— *Medium A.* To 50.0 mL of modified medium 199 add 440.0 mL of *water R,* 5.0 mL of L-glutamine 200 mM solution and 10.0 mL of sodium bicarbonate 7.5 per cent solution.
— *Medium B.* To 150.0 mL of medium A add 3.0 mL of foetal bovine serum and 0.3 mL of penicillin/streptomycin solution.
— *Medium C.* To 22.0 mL of medium A add 0.44 mL of foetal bovine serum and 0.44 mL of penicillin/streptomycin solution.

Vero cells are cultured in tissue culture flasks (for example 75 cm^2/250 mL) in an incubator at 36 ± 1 °C, 5 per cent CO_2 and 90 per cent relative humidity. Vero cells

are first grown in the primary culture medium. After 2-3 days of growth, the primary culture medium is replaced by the maintenance culture medium. When a confluent monolayer is obtained, the culture supernatant is discarded and the cell layer washed gently with modified D-PBS. Add a mixture of 1 volume of trypsin solution and 1 volume of EDTA solution to the flask. Swirl the flask gently and incubate in the CO_2 incubator for about 3 min until the cells start to break from the monolayer. Vigorously tap the side of the flask to make the cells fall. Resuspend the cells in 5-6 mL of fresh medium C to obtain a homogeneous suspension. Prepare a cell suspension in medium C containing approximately 1×10^5 cells/mL.

Place 25 µL of medium B in each well except those of column 1. Place 25 µL of the diphtheria guinea-pig antiserum (for vaccines-human use) (positive control serum, working dilution in medium B of 0.40 IU/mL) in wells A1, A2 and A11. Place 25 µL of guinea-pig serum samples in wells B-G of columns 1, 2 and 11. Place 25 µL of negative control serum in row H of columns 1, 2 and 11. Using a multichannel micropipette, make twofold serial dilutions across the plate (from column 2 up to column 10 for rows A-G and up to column 8 for row H). Discard 25 µL from the wells in column 10 in rows A-G, and from well H8.

Reconstitute the diphtheria toxin with saline solution to give a solution of 50 IU/mL. Prepare a 50-fold dilution of this diphtheria toxin dilution in medium B to obtain a working solution of 1.0 IU/mL. Add 25 µL of this working solution to wells A12 and B12 (toxin control). Make twofold serial dilutions by tranferring 25 µL from one well to the next, from well B12 down to H12. Change the tip between each dilution. Discard 25 µL from well H12. Add 25 µL of medium B to wells B12-H12. Then, place 25 µL of the working dilution of the diphtheria toxin (1.0 IU/mL) in each well of rows A-H, from column 1-10, except in wells H9 and H10 (cells only, without serum and without toxin).

Cover the plates with lids or sealer and shake gently. Incubate the plates for at least 2 h in a humid container in a CO_2 incubator at 37 °C. Add 200 µL of cell suspension containing 1×10^5 cells/mL to all the wells. Cover the plates with sealer. Incubate at 37 °C for 5 days. Check for microbial contamination by microscopic examination.

Yellow wells are recorded as negative and red wells indicate dead cells and are recorded as positive. A colour between yellow and red indicates a mixture of viable and dead cells and is recorded as positive/negative. The results based on the change in colour can be confirmed by reading viable and dead cells under the microscope.

The potency of the guinea-pig antiserum samples is obtained by comparing the last well of the standard preparation showing complete neutralisation of the toxin, with the last well of the sample demonstrating the same effect.
For calculations of potency, it must be remembered that the endpoint may be between a negative well and a positive/negative well.

Method 2 Thiazolyl blue MTT is reduced to a blue/black formazan product by the mitochondrial dehydrogenase of viable cells, and thus serves as a quantitative measure of living cells present, indicating when the toxin has been neutralised by the antitoxin. White or colourless wells indicate absence of viable cells due to insufficient antitoxin to neutralise the toxin.

Reagents and equipment

- *MEM* (Minimal Essential Media).
- *Newborn calf serum.*
- *Antibiotic solution* (containing 10 000 units of penicillin, 10 mg of streptomycin and 25 µg of amphotericin B per millilitre).
- *L-glutamine 200mM solution.*
- *Trypsin-EDTA.*
- *Thiazolyl blue MTT* [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide].
- *1 M HEPES buffer pH 8.1.* Dissolve 18.75 g of HEPES in 82.5 mL of *water R* and 30.0 mL of *2 M sodium hydroxide R.*
- *Glucose solution (10 per cent).*
- *Complete culture medium.* Mix 200 mL of MEM with 10 mL of newborn calf serum, 3.0 mL of 1 M HEPES buffer pH 8.1, 2.0 mL of glucose solution (10 per cent), 2.0 mL of antibiotic solution and 2.0 mL of L-glutamine 200mM solution.
- *Phosphate-buffered saline pH 7.4 (PBS).* Dissolve 10.0 g of *sodium chloride R*, 0.75 g of *potassium chloride R*, 1.44 g of *disodium hydrogen phosphate dodecahydrate R*, and 0.125 g of *potassium dihydrogen phosphate R* in *water R*, and dilute to 1000.0 mL with the same solvent. Adjust the pH if necessary. Autoclave at 120 °C for 15 min.
- *Thiazolyl blue MTT solution.* Dissolve 0.1 g of thiazolyl blue MTT in 20 mL of PBS. Sterilise by filtration (0.2 µm) and store in dark bottle.
- *pH adjuster solution.* Mix 40 mL of *acetic acid R* with 1.25 mL of *1 M hydrochloric acid* and 8.75 mL of *water R.*
- *Extraction buffer pH 4.7.* Dissolve 10 g of *sodium laurilsulfate R* in *water R* and add 50 mL of *dimethylformamide R*, and dilute to 100 mL with *water R.* Adjust the pH with an appropriate volume of pH adjuster solution.

Vero cells are cultured in tissue culture flasks (for example 75 cm^2/250 mL) in an incubator at 36 ± 1 °C, 5 per cent CO_2 and 90 per cent relative humidity. Vero cells are grown in the complete culture medium. After 6-7 days of growth, a confluent monolayer is obtained, the culture supernatant is discarded and the cell layer is washed 3 times with trypsin-EDTA: gently pipette out the medium, add 0.5-1 mL of trypsin-EDTA, swirl the flask and tip the trypsin out. Do this twice, and the 3rd time, place the flask in the incubator for 5 min until the cells start to break from the monolayer. Vigorously tap the side of the flask to make the cells fall. Resuspend the cells in 6-25 mL of fresh complete culture medium to obtain a homogeneous suspension. Prepare a cell suspension in complete culture medium containing approximately 4×10^5 cells/mL.

Place 50 µL of complete culture medium in each well except those of column 1. Place 100 µL of diphtheria guinea pig antiserum (for vaccines-human use) (positive control serum, working dilution in complete culture medium of 0.12 IU/mL) in well A1 and 50 µL in well A11. Place 100 µL of guinea pig test serum samples, diluted if necessary, in wells B1-G1. Add 50 µL of the same sample to wells B11-G11 in the corresponding row. Place 100 µL of negative control serum in well H1 and 50 µL in well H11. Using a multi-channel micropipette, make twofold serial dilutions by transferring 50 µL from one well to the next working across the plate (from column 1-10 for rows A-G and from column 1-8 for row H).

Diphtheria toxin of known activity and Lf content is diluted to a suitable working stock containing at least 4 minimum cytopathic doses in complete culture medium. Add 50 µL of the diluted toxin to each well except H9 and H10 (cell control), A11-H11 (serum control) and A12-H12 (toxin control). Add 100 µL of diluted toxin to well A12 and make

twofold serial dilutions by transferring 50 µL from one well to the next working down the plate (from well A12-H12). Discard 50 µL from well H12. Add 50 µL of complete medium to wells H9 and H10.

Cover the plates with a lid or sealer and leave for 1 h at room temperature to allow toxin neutralisation to occur. 50 µL of cell suspension containing approximately 4×10^5 cells/mL is added to each well. The plates are sealed and incubated at 37 °C for 6 days. Check for microbial contamination by microscopic examination. 10 µL of thyazolyl blue MTT solution is added to each well. The plates are incubated at 37 °C for a further 2-4 h. Then, the medium is removed and 100 µL of extraction buffer pH 4.7 is added to each well. The plates are incubated at 37 °C and left overnight to aid the extraction process. Once extraction and solubilisation is complete, plates are visually examined or read at 570 nm.

Blue/black wells are recorded as negative (all the cells are alive, toxin neutralisation by antitoxin) and white or colourless wells indicate dead cells (no toxin neutralisation) and are recorded as positive.

The potency of the test antitoxin is obtained by comparing the last well of the reference antitoxin preparation showing neutralisation of the toxin, with the last well of the antitoxin preparation demonstrating the same effect. The neutralising antibody titre of the sample being examined can be calculated by multiplication of the dilution factor with total number of International Units per millilitre of the reference preparation at the end point. The test is valid if all the cells in the toxin control are dead and reference antitoxin gives a neutralisation in at least the first 2 dilutions tested.

2. Assay of Pertussis Vaccine (Whole Cell)

(Ph. Eur. method 2.7.7)

The potency of pertussis vaccine (whole cell) is determined by comparing the dose necessary to protect mice against the effects of a lethal dose of *Bordetella pertussis*, administered intracerebrally, with the quantity of a reference preparation, calibrated in International Units, needed to give the same protection.

The International Unit is the activity contained in a stated amount of the International Standard which consists of a quantity of dried pertussis vaccine. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Selection and distribution of the test animals

Use in the test healthy mice less than 5 weeks old of a suitable strain from the same stock, the difference in mass between the heaviest and the lightest being not greater than 5 g. Distribute the mice in 6 groups of not fewer than 16 and 4 groups of 10. The mice must all be of the same sex or the males and females distributed equally between the groups.

Selection of the challenge strain and preparation of the challenge suspension

Select a suitable strain of *B. pertussis* capable of causing the death of mice within 14 days of intracerebral injection. If more than 20 per cent of the mice die within 48 h of the injection the strain is not suitable. Make one subculture from the strain and suspend the harvested *B. pertussis* in a solution containing 10 g/L of *casein R* hydrolysate and 6 g/L of *sodium chloride R* and having a pH of 7.0 to 7.2 or in another suitable solution. Determine the opacity of the suspension. Prepare a series of dilutions in the same solution and allocate each dilution to a group of 10 mice. Inject intracerebrally into each mouse a dose (0.02 mL or 0.03 mL) of the dilution allocated to its group. After 14 days, count the number of mice surviving in each group. From the results, calculate the expected opacity of a suspension containing 100 LD_{50} in each challenge dose. For the test of the vaccine to be examined make a fresh subculture from the same strain of *B. pertussis* and prepare a suspension of the harvested organisms with an opacity corresponding to about 100 LD_{50} in each challenge dose. Prepare 3 dilutions of the challenge suspension.

Determination of potency

Prepare 3 serial dilutions of the vaccine to be examined and 3 similar dilutions of the reference preparation such that in each the intermediate dilution may be expected to protect about 50 per cent of the mice from the lethal effects of the challenge dose of *B. pertussis*. Suggested doses are 1/8, 1/40 and 1/200 of the human dose of the vaccine to be examined and 0.5 IU, 0.1 IU and 0.02 IU of the reference preparation, each dose being contained in a volume not exceeding 0.5 mL. Allocate the 6 dilutions, one to each of the groups of not fewer than 16 mice, and inject intraperitoneally into each mouse one dose of the dilution allocated to its group. After 14 - 17 days inject intracerebrally into each animal in the groups of not fewer than 16, one dose of the challenge suspension. Allocate the challenge suspension and the 3 dilutions made from it, one to each of the groups of 10 mice, and inject intracerebrally one dose of each suspension into each mouse in the group to which that suspension is allocated. Exclude from consideration any mice that die within 48 h of challenge. Count the number of mice surviving in each of the groups after 14 days. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the numbers of animals surviving in each of the groups of not fewer than 16.

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and the smallest doses given to the mice;
- the number of animals that die in the 4 groups of 10 injected with the challenge suspension and its dilutions indicates that the challenge dose is approximately 100 LD_{50}; and
- the statistical analysis shows no deviation from linearity or parallelism.

The test may be repeated but when more than one test is performed the results of all valid tests must be combined.

3. Assay of Tetanus Vaccine (Adsorbed)

(Ph. Eur. method 2.7.8)

The potency of tetanus vaccine is determined by administration of the vaccine to animals (guinea-pigs or mice) followed either by challenge with tetanus toxin (method A or B) or by determination of the titre of antibodies against tetanus toxoid in the serum of the guinea-pigs (method C). In both cases, the potency of the vaccine is calculated by comparison with a reference vaccine, calibrated in International Units. For methods A and B, in countries where the paralysis method is not obligatory, the LD_{50} method may be used. For the LD_{50} method, the number of animals and the procedure are identical to those described for the paralysis method, but the end-point is the death of the animal rather than paralysis.

The International Unit is the activity contained in a stated amount of the International Standard for tetanus toxoid (adsorbed). The equivalence in International Units of the International Standard is stated by the World Health Organization.

Tetanus vaccine (adsorbed) BRP is calibrated in International Units with reference to the International Standard.

The method chosen for the assay of tetanus vaccine (adsorbed) depends on the intended purpose. Method A or B is used:

1. during development of a vaccine, to assay batches produced to validate the production;

2. wherever revalidation is needed following a significant change in the manufacturing process.

Method A or B may also be used for the routine assay of batches of vaccine, but in the interests of animal welfare, method C is used wherever possible.

Method C may be used, except as specified under 1 and 2 above, after verification of the suitability of the method for the product. For this purpose, a suitable number of batches (usually 3) are assayed by method C and method A or B. Where different vaccines (monovalent or combinations) are prepared from tetanus toxoid of the same origin and with comparable levels (expressed in Lf/mL) of the same tetanus toxoid, suitability demonstrated for the combination with the highest number of components can be assumed to be valid for combinations with fewer components and for monovalent vaccines. Any combinations containing a whole-cell pertussis component or containing haemophilus type b conjugate vaccine with tetanus toxoid in the same vial must always be assessed separately.

For combinations containing diphtheria and tetanus components, the serological assay (method C) can be performed with the same group of animals used for the serological assay of the diphtheria vaccine (adsorbed) (*2.7.6*) when the common immunisation conditions for the tetanus and the diphtheria components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine.

The design of the assays described below uses multiple dilutions for the test and reference preparations. Based on the potency data obtained in multiple-dilution assays, it may be possible to reduce the number of animals needed to obtain a statistically significant result by applying a simplified model such as a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required, but does not give information on the dose-response curves and their linearity, parallelism and significant slope. The simplified model allows for a considerable reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes.

Where a single-dilution assay is used, production and test consistency over time are monitored via suitable indicators and by carrying out a full multiple-dilution assay periodically, for example every 2 years. For serological assays, suitable indicators to monitor test consistency are:

- the mean and standard deviation of relative antitoxin titres or scores of the serum samples obtained after administration of a fixed dose of the vaccine reference preparation;
- the antitoxin titres or scores of run controls (positive and negative serum samples);
- the ratio of antitoxin titres or scores for the positive serum control to the serum samples corresponding to the reference vaccine.

METHOD A. CHALLENGE TEST IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the activity of the challenge toxin has to be determined, include 3 further groups of 5 guinea-pigs as unvaccinated controls.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of tetanus toxin containing not less than 50 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose per millilitre. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/L solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 mL per guinea-pig, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 mL of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 1.0 mL of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of 5 guinea-pigs, and inject subcutaneously 1.0 mL of each solution into each guinea-pig in the group to which that solution is allocated. The activity and stability of the challenge toxin are determined by carrying out a suitable number of determinations of the 50 per cent paralytic dose. It is then not necessary to repeat the determination for each assay.

READING AND INTERPRETATION OF RESULTS

Examine the guinea-pigs twice daily. Remove and euthanise all animals showing definite signs of tetanus paralysis. Count the number of guinea-pigs without paralysis 5 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each group of vaccinated guinea-pigs, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the guinea-pigs;
- where applicable, the number of paralysed animals in the 3 groups of 5 injected with the dilutions of the challenge toxin solution indicates that the challenge was approximately 50 times the 50 per cent paralytic dose;
- the confidence limits (P = 0.95) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD B. CHALLENGE TEST IN MICE

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Use mice of the same sex or with males and females equally distributed between the groups. Distribute the mice in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 3 further groups of not fewer than 5 mice to serve as unvaccinated controls.

SELECTION OF THE CHALLENGE TOXIN

Select a preparation of tetanus toxin containing not less than 100 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

PREPARATION OF THE CHALLENGE TOXIN SOLUTION

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose in 0.5 mL. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/L solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 0.5 mL per mouse, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

IMMUNISATION AND CHALLENGE

Allocate the dilutions, 1 to each of the groups of mice, and inject subcutaneously 0.5 mL of each dilution into each mouse in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 0.5 mL of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of not fewer than 5 mice, and inject subcutaneously 0.5 mL of each solution into each mouse in the group to which that solution is allocated.

READING AND INTERPRETATION OF RESULTS

Examine the mice twice daily. Remove and euthanise all animals showing definite signs of tetanus paralysis. Count the number of mice without paralysis 4 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each group of vaccinated mice, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the mice;
- where applicable, the number of paralysed animals in the 3 groups of not fewer than 5 injected with the dilutions of the challenge toxin solution, indicates that the challenge dose was approximately 50 times the 50 per cent paralytic dose;
- the confidence limits (P = 0.95) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

SELECTION AND DISTRIBUTION OF THE TEST ANIMALS

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. Use a further group of non-vaccinated guinea-pigs of the same origin to provide a negative serum control. If test consistency has been demonstrated, a reference negative serum control may be used.

REFERENCE PREPARATION

Use a suitable reference preparation such as *tetanus vaccine (adsorbed) BRP* or a batch of vaccine shown to be effective in clinical studies, or a batch representative thereof, and which has been calibrated in International Units with reference to *tetanus vaccine (adsorbed) BRP* or the International Standard for tetanus toxoid (adsorbed).

DILUTION OF THE TEST AND REFERENCE PREPARATIONS

Using a 9 g/L solution of *sodium chloride R* as diluent, prepare serial dilutions of the vaccine to be examined and the

reference preparation; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range of, for example, 0.5-16 IU/mL for each series. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

IMMUNISATION

Inject subcutaneously to each guinea-pig 1.0 mL of the dilution allocated to its group.

BLOOD SAMPLING

35-42 days after immunisation, take a blood sample from each vaccinated and control guinea-pig using a suitable method.

PREPARATION OF SERUM SAMPLES

Avoid frequent freezing and thawing of serum samples. To avoid microbial contamination, it is preferable to carry out manipulations in a laminar-flow cabinet.

DETERMINATION OF ANTIBODY TITRE

Determine the relative antibody titre or score of each serum sample by a suitable immunochemical method (*2.7.1*). The methods shown below (enzyme-linked immunosorbent assay (ELISA) and toxin-binding inhibition (ToBI)) have been found to be suitable.

CALCULATION OF POTENCY

Calculate the potency of the vaccine to be examined in International Units relative to the reference preparation, using the usual statistical methods (for example, *5.3*).

REQUIREMENTS FOR A VALID ASSAY

The test is not valid unless:

— the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;

— the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

The following section is published for information.

ASSAY OF TETANUS VACCINE (ADSORBED): GUIDELINES

METHOD A. CHALLENGE TEST IN GUINEA-PIGS

READING AND INTERPRETATION OF RESULTS

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when subcutaneous injection of the challenge toxin is made mid-ventrally, directly behind the sternum with the needle pointing towards the neck of the guinea-pig. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in at least 1 of the forelimbs paralysis that can be recognised at an early stage. The tetanus grades in guinea-pigs are characterised by the following signs:

— T1: slight stiffness of 1 forelimb, but difficult to observe;

— T2: paresis of 1 forelimb which still can function;

— T3: paralysis of 1 forelimb. The animal moves reluctantly, the body is often slightly banana-shaped owing to scoliosis;

— T4: the forelimb is completely stiff and the toes are immovable. The muscular contraction of the forelimb is very pronounced and usually scoliosis is observed;

— T5: tetanus seizures, continuous tonic spasm of muscles;

— D: death.

METHOD B. CHALLENGE TEST IN MICE

READING AND INTERPRETATION OF RESULTS

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when injection of the challenge toxin is made in the dorsal region, close to one of the hind legs. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in the toxin-injected hind leg paresis followed by paralysis that can be recognised at an early stage. The tetanus grades in mice are characterised by the following signs:

— T1: slight stiffness of toxin-injected hind leg, only observed when the mouse is lifted by the tail;

— T2: paresis of the toxin-injected hind leg, which still can function for walking;

— T3: paralysis of the toxin-injected hind leg, which does not function for walking;

— T4: the toxin-injected hind leg is completely stiff with immovable toes;

— T5: tetanus seizures, continuous tonic spasm of muscles;

— D: death.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

PREPARATION OF SERUM SAMPLES

For the preparation of serum samples, the following technique has been found to be suitable. Invert the tubes containing blood samples 6 times and allow to stand at 37 °C for 2 h, then at 4 °C for 2 h. Centrifuge at room temperature at 800 *g* for 20 min. Transfer the serum to sterile tubes and store at a temperature below −20 °C. At least a 40 per cent yield of serum is obtained by this procedure.

DETERMINATION OF ANTIBODY TITRE

The ELISA and ToBI tests shown below are given as examples of immunochemical methods that have been found to be suitable for the determination of antibody titre.

Determination of antibody titre in guinea-pig serum by enzyme-linked immunosorbent assay (ELISA)

Dilutions of test and reference sera are made on ELISA plates coated with tetanus toxoid. A positive guinea-pig serum control and a negative guinea-pig serum control are included on each plate to monitor the assay performance. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig-IgG is added, followed by a peroxidase substrate. Optical density is measured and the relative antibody titre is calculated using the usual statistical methods (for example, *5.3*).

Reagents and equipment

— *ELISA plates*: 96 wells, columns 1-12, rows A-H.

— *Clostridium tetani guinea-pig antiserum (for vaccines-human use) BRP* (positive control serum).

— *Peroxidase conjugate.* Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.

— *Tetanus toxoid.*

— *Carbonate coating buffer pH 9.6.* Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 mL of *water R*. Distribute into 150 mL bottles and sterilise by autoclaving at 121 °C for 15 min.

— *Phosphate-buffered saline pH 7.4 (PBS).* Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen*

phosphate dihydrate R and 2.0 g of *potassium chloride R* in 1000 mL of *water R*. Store at room temperature to prevent crystallisation. Dilute to 10 times its volume with *water R* before use.

— *Citric acid solution.* Dissolve 10.51 g of *citric acid monohydrate R* in 1000 mL of *water R* and adjust the solution to pH 4.0 with a 400 g/L solution of *sodium hydroxide R*.

— *Washing buffer.* PBS containing 0.5 g/L of *polysorbate 20 R*.

— *Diluent block buffer.* PBS containing 0.5 g/L of *polysorbate 20 R* and 25 g/L of dried skimmed milk.

— *Peroxidase substrate.* Shortly before use, dissolve 10 mg of *diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonate) R* (ABTS) in 20 mL of citric acid solution. Immediately before use add 5 µL of *strong hydrogen peroxide solution R*.

Method

The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are for negative control serum and wells 2A-H and 12A-H are for positive control serum for assay monitoring. Wells 3-11A-H are for test samples.

Coat each well of the ELISA plates with 100 µL of tetanus toxoid solution (0.5 Lf/mL in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with washing buffer. Block the plates by addition of 100 µL of diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing buffer. Place 100 µL of diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of negative control serum, positive control serum (from about 0.01 IU/mL) and test sera. Allocate the negative control serum to column 1, positive control serum to columns 2 and 12 and test sera to columns 3-11 and add 100 µL of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make twofold serial dilutions from row B down the plate to row H, by transferring 100 µL from one well to the next. Discard 100 µL from the last row so that all wells contain 100 µL. Incubate at 37 °C for 2 h. Wash thoroughly with washing buffer. Prepare a suitable dilution (a 2000-fold dilution has been found to be suitable) of peroxidase conjugate in diluent block buffer and add 100 µL to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing buffer. Add 100 µL of peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as addition of substrate was made.

Determination of antibody titre in guinea-pig serum by toxin- or toxoid-binding inhibition (ToBI)

Tetanus toxin or toxoid is added to serial dilutions of test and reference sera; the serum/antigen mixtures are incubated overnight. To determine unbound toxin or toxoid, the mixtures are transferred to an ELISA plate coated with tetanus antitoxin. Peroxidase-conjugated equine anti-tetanus IgG is added followed by a peroxidase substrate. Optical density is measured and the antibody titre is calculated using the usual statistical methods (for example, *5.3*). A positive control serum and a negative control serum are included on each plate to monitor assay performance.

Reagents and equipment

— *Round-bottomed, rigid polystyrene microtitre plates.*

— *Flat-bottomed ELISA plates.*

— *Tetanus toxin or tetanus toxoid.*

— *Clostridium tetani guinea-pig antiserum (for vaccines-human use) BRP* (positive control serum).

— *Equine anti-tetanus IgG.*

— *Peroxidase-conjugated equine anti-tetanus IgG.*

— *Carbonate buffer pH 9.6.* Dissolve 1.5 g of *anhydrous sodium carbonate R*, 2.39 g of *sodium hydrogen carbonate R* and 0.2 g of *sodium azide R* in 1000 mL of *water R*, adjust to pH 9.6 and autoclave at 121 °C for 20 min.

— *Sodium acetate buffer pH 5.5.* Dissolve 90.2 g of *anhydrous sodium acetate R* in 900 mL of *water R*, adjust to pH 5.5 using a saturated solution of *citric acid monohydrate R* and dilute to 1000 mL with *water R*.

— *Phosphate-buffered saline pH 7.2 (PBS).* Dissolve 135.0 g of *sodium chloride R*, 20.55 g of *disodium hydrogen phosphate dihydrate R* and 4.80 g of *sodium dihydrogen phosphate monohydrate R* in *water R* and dilute to 15 L with the same solvent. Autoclave at 100 °C for 60 min.

— *Diluent buffer.* PBS containing 5 g/L of *bovine albumin R* and 0.5 g/L of *polysorbate 80 R*.

— *Block buffer.* PBS containing 5 g/L of *bovine albumin R*.

— *Tetramethylbenzidine solution.* 6 g/L solution of *tetramethylbenzidine R* in *ethanol (96 per cent) R*. The substance dissolves within 30-40 min at room temperature.

— *Peroxidase substrate.* Mix 90 mL of *water R*, 10 mL of sodium acetate buffer pH 5.5, 1.67 mL of tetramethylbenzidine solution and 20 µL of *strong hydrogen peroxide solution R*.

— *Washing solution.* Tap water containing 0.5 g/L of *polysorbate 80 R*.

Method

Block the microtitre plates by placing in each well 150 µL of block buffer. Cover the plates with a lid or sealer. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing solution. Place 100 µL of PBS in each well. Place 100 µL of reference guinea-pig tetanus antitoxin in the first well of a row. Place 100 µL of undiluted test sera in the first well of the required number of rows. Using a multichannel micropipette, make twofold serial dilutions across the plate (up to column 10), by transferring 100 µL from one well to the next. Discard 100 µL from the last column so that all wells contain 100 µL. Prepare a 0.1 Lf/mL solution of tetanus toxin or toxoid using PBS as diluent. Add 40 µL of this solution to each well except those of column 12. The wells of column 11 are a positive control. Add 40 µL of PBS to the wells of column 12 (negative control). Shake the plates gently and cover them with lids. Coat the ELISA plates: immediately before use make a suitable dilution of equine anti-tetanus IgG in carbonate buffer pH 9.6 and add 100 µL to each well. Incubate the 2 series of plates overnight in a humid atmosphere at 37 °C. To avoid temperature gradient effects, do not stack more than 4 plates high. Cover the plates with lids. On the following day, wash the ELISA plates thoroughly with washing solution. Block the plates by placing in each well 125 µL of block buffer. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing solution. Transfer 100 µL of the pre-incubation mixture from the polystyrene plates to the corresponding wells of the ELISA plates, starting with column 12 and then continuing from 1 to 11. Cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 2 h. Wash the ELISA plates

thoroughly with washing solution. Make a suitable dilution (a 4000-fold dilution has been found to be suitable) of the peroxidase-conjugated equine anti-tetanus IgG in diluent buffer. Add 100 µL of the dilution to each well and cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 1.5 h. Wash the ELISA plates thoroughly with washing solution. Add 100 µL of peroxidase substrate to each well. A blue colour develops. Incubate the plates at room temperature. Stop the reaction at a given time (within 10 min) by the addition of 100 µL of a 2 M solution of sulfuric acid prepared from *sulfuric acid R* to each well in the same order as the addition of substrate. The colour changes from blue to yellow. Measure the absorbance at 450 nm immediately after addition of the sulfuric acid or maintain the plates in the dark until reading.

4. Assay of Hepatitis A Vaccine

(Ph. Eur. method 2.7.14)

The assay of hepatitis A vaccine is carried out either *in vitro*, by an immunochemical determination of the antigen content (method A), or *in vivo*, by comparing under given conditions its capacity to induce specific antibodies in mice with the same capacity of a reference preparation (method B).

METHOD A. *IN VITRO* ASSAY

Carry out an immunochemical determination (*2.7.1*) of the hepatitis A antigen content.

Enzyme-linked immunosorbent assay (ELISA) using monoclonal antibodies specific for the detection of a hepatitis A epitope that induces neutralising antibodies has been shown to be suitable.

Suitable numbers of dilutions of the vaccine to be examined and the reference preparation are used, and the potency of the vaccine to be examined is calculated using the usual statistical methods (*5.3*).

The antigen content is within the limits approved for the particular product.

Hepatitis A vaccine (inactivated, non-adsorbed) BRP is calibrated in International Units and may be used as a reference preparation.

METHOD B. *IN VIVO* ASSAY

The test in mice shown below is given as an example of a method that has been found suitable for a given vaccine; other validated methods may also be used.

Selection and distribution of the test animals

Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number suitable for the requirements of the assay.

Determination of potency of the vaccine to be examined

Using a 9 g/L solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine, prepare at least 3 dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions one to each of the groups of animals and inject subcutaneously not more than 1.0 mL of each dilution into each animal in the group to which that dilution is allocated. Maintain a group of unvaccinated controls, injected subcutaneously with the same volume of diluent. After 28-32 days, anaesthetise and bleed all animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against hepatitis A virus by a suitable immunochemical method (*2.7.1*).

Calculations

Carry out the calculations by the usual statistical methods for an assay with a quantal response (*5.3*).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, determine the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay. Any response in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

Validity conditions

The test is not valid unless:

- for both the test and the reference vaccine, the ED_{50} lies between the smallest and the largest doses given to the animals;
- the statistical analysis shows no significant deviation from linearity or parallelism;
- the confidence limits ($P = 0.95$) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement

The upper confidence limit ($P = 0.95$) of the estimated relative potency is not less than 1.0.

5. Assay of Hepatitis B Vaccine (rDNA)

(Ph. Eur. method 2.7.15)

The assay of hepatitis B vaccine (rDNA) is carried out either *in vivo*, by comparing in given conditions its capacity to induce specific antibodies against hepatitis B surface antigen (HBsAg) in mice or guinea-pigs with the same capacity of a reference preparation, or *in vitro*, by an immunochemical determination of the antigen content.

IN VIVO ASSAY

Selection and distribution of the test animals

Use in the test healthy mice from the same stock, about 5 weeks old. The strain of mice used for this test must give a significant slope for the dose-response curve to the antigen; mice with haplotype H-2^q or H-2^d are suitable. Healthy guinea-pigs weighing 300 g to 350 g (about 7 weeks old) from the same stock are also suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number appropriate to the requirements of the assay.

Determination of potency of the vaccine to be examined

Using a 9 g/L solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine or another appropriate diluent, prepare at least 3 dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions, 1 to each of the groups of animals, and inject intraperitoneally not more than 1.0 mL of each dilution into each animal in the group to which that dilution is allocated. One group of animals remains unvaccinated and is injected intraperitoneally with the same volume of diluent. After an appropriate time interval (for example, 4-6 weeks), anaesthetise and bleed the animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against HBsAg by a suitable immunochemical method (*2.7.1*).

Calculations

Calculations are carried out by the usual statistical methods for an assay with a quantal response (*5.3*).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay is determined. Any response in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

Validity conditions

The test is not valid unless:

— for both the test and the reference vaccine, the ED_{50} lies between the smallest and the largest doses given to the animals;

— the statistical analysis shows no significant deviation from linearity or parallelism;

— the confidence limits ($P = 0.95$) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement

The upper confidence limit ($P = 0.95$) of the estimated relative potency is not less than 1.0.

***IN VITRO* ASSAY**

Carry out an immunochemical determination (*2.7.1*) of antigen content with acceptance criteria validated against the *in vivo* test.

Enzyme-linked immunosorbent assay (ELISA) and radio-immunoassay (RIA) using monoclonal antibodies specific for protection-inducing epitopes of HBsAg have been shown to be suitable. Suitable numbers of dilutions of the vaccine to be examined and the reference preparation are used and a parallel-line model is used to analyse the data, which may be suitably transformed. Kits for measuring HBsAg *in vitro* are commercially available and it is possible to adapt their test procedures for use as an *in vitro* potency assay.

The acceptance criteria are approved for a given reference preparation by the competent authority in light of the validation data.

6. Assay of Pertussis Vaccine (Acellular)

(Ph. Eur. method 2.7.16)

The assay of acellular pertussis vaccine measures the capacity of the vaccine to induce the formation of specific antibodies in mice or guinea-pigs. Antibody titres for each antigen are determined using a suitable immunochemical method (*2.7.1*) such as enzyme-linked immunosorbent assay (ELISA).

The assay results can be expressed:

— either as a ratio of the geometric mean titre (GMT) of antibodies produced following administration of the test vaccine to the GMT of antibodies produced following administration of a reference vaccine examined in parallel (relative potency assay);

— or directly as a GMT of antibodies induced by the test vaccine (geometric mean unit assay or GMU assay).

For combinations containing pertussis components together with diphtheria and tetanus components, the serological assay in guinea-pigs can be performed with the same group of animals used for the serological assay of diphtheria vaccine (adsorbed) (*2.7.6*) and of tetanus vaccine (adsorbed) (*2.7.8*) when the common immunisation conditions for all components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine.

The guinea-pig model allows for a further reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes.

Methods A and B described below are developed by testing multiple dilutions of the test vaccine and the reference vaccine or internal control (see Glossary), to determine which dilutions are suitable. Once the suitable dilutions have been confirmed for a given vaccine, it is recommended, in accordance with 3R principles (Replacement, Reduction, Refinement), to apply a simplified model such as a single dilution for both the test vaccine and the reference vaccine or internal control. Such a model enables the analyst to determine whether the immunogenicity of the test vaccine is satisfactory.

Suitable indicators to monitor the performance of the serological assay (single or multiple dilutions) are:

— the geometric mean and geometric standard deviation of antibody titres in the serum samples obtained after administration of a fixed dose of the reference vaccine or internal control;

— the antibody titres of run controls (positive control and negative serum samples).

It may be necessary to reconfirm the suitability of the selected dilution with a multiple-dilution assay, e.g. after major process changes or for investigational purposes.

METHOD A. SEROLOGY IN MICE

The following test model is given as an example of a multiple-dilution assay which may form the basis for the establishment of a single-dilution assay.

Selection and distribution of the test animals

Use healthy mice (for example, CD1 strain from the same stock and more than 5 weeks old). Distribute the animals into not fewer than 6 equal groups; use groups containing a number of animals sufficient to meet the pre-defined criteria for variability of the antibody responses prescribed under Calculations and validity criteria. Use serial dilutions of the test vaccine and the reference vaccine or internal control and allocate each dilution to a group of mice. During validation studies a further group of mice may be used as a negative control by injecting the animals with diluent alone.

Immunisation

Inject intraperitoneally or subcutaneously into each mouse 0.5 mL of the dilution allocated to its group.

Collection of serum samples

4-5 weeks after vaccination, bleed the mice individually under anaesthesia. Store the sera at −20 °C until used for antibody determination. Avoid frequent freezing and thawing of serum samples.

Reference antiserum

A reference antiserum of assigned activity serves as the basis for calculation of the antibody titres in the test sera. *Bordetella pertussis mouse antiserum BRP* is suitable for use as a reference antiserum.

Antibody determination

Assay the individual sera for content of specific antibodies against each acellular pertussis antigen using a validated method such as the ELISA test shown below.

ELISA test

Microtitre plates (poly(vinyl chloride) or polystyrene as appropriate for the specific antigen) are coated with the purified antigen at a concentration of 100 ng per well. After washing, unreacted sites are blocked by incubating the plates

with a solution of bovine serum albumin and then washed. 2-fold dilutions of sera from individual mice immunised with the test vaccine or either the reference vaccine or the internal control are prepared on the plates. Reference antiserum is included on each plate. After incubation at 22-25 °C for 1 h, the plates are washed. A suitable solution of enzyme-conjugated anti-mouse IgG antibody is added to each well and incubated at 22-25 °C for 1 h. After washing, a chromogenic substrate is added from which the bound enzyme conjugate liberates a chromophore that can be quantified by measurement of absorbance (*2.2.25*).

METHOD B. SEROLOGY IN GUINEA-PIGS

The following test model is given as an example of a multiple-dilution assay which may form the basis for the establishment of a single-dilution assay.

Selection and distribution of the test animals

Use healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs into not fewer than 6 equal groups; use groups containing a number of animals sufficient to meet the pre-defined criteria for variability of the antibody responses prescribed under Calculations and validity criteria. During validation studies a further group of guinea-pigs may be used as a negative control by injecting the animals with diluent alone.

Dilution of the test and reference preparations

Using a 9 g/L solution of *sodium chloride R* as diluent, prepare serial dilutions of the test vaccine and the reference vaccine or internal control; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range found to be suitable for all the components in the test vaccine. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

Immunisation

Inject subcutaneously into each guinea-pig 1.0 mL of the dilution allocated to its group.

Collection of serum samples

5-6 weeks after immunisation, take a blood sample from each vaccinated and negative control guinea-pig using a suitable method. Store the sera at −20 °C until used for antibody determination. Avoid frequent freezing and thawing of serum samples.

Reference antiserum

An in-house guinea-pig reference antiserum of assigned activity serves as the basis for calculation of the antibody titres in the test sera.

Antibody determination

Assay the individual sera for content of specific antibodies against each acellular pertussis antigen using a validated method such as the ELISA test shown below.

ELISA test

Suitable 96-well microtitre plates are coated with the purified antigens (e.g. pertussis toxin (PT), pertactin (PRN), filamentous haemagglutinin (FHA) and/or fimbrial agglutinogens (Fim 2/3)) representing components in the combined vaccine at a concentration of 200-400 ng per well. After washing, unreacted sites are blocked by incubating the plates with a suitable blocking buffer and then washed. 2-fold dilutions of sera from individual guinea-pigs immunised with the test vaccine or either the reference vaccine or the internal control are prepared on the plates. Reference antiserum is included on each plate. After incubation at 37 °C for 1 h, the plates are washed. A suitable solution of enzyme-conjugated anti-guinea-pig IgG antibody is added to each well and incubated at 37 °C for 1 h. After washing, a chromogenic substrate is added from which the bound enzyme conjugate liberates a chromophore that can be quantified by measurement of absorbance (*2.2.25*).

CALCULATIONS AND VALIDITY CRITERIA

Relative potency assay

The antibody titres in the sera of mice or guinea-pigs immunised with the test and reference vaccines are determined for each acellular pertussis antigen using the reference antiserum. From the values obtained, the GMT ratio of the test vaccine in relation to the reference vaccine is calculated for each antigen.

The relative potency assay is not valid unless:

- the number of responder animals for the test and reference vaccines meets the pre-defined criteria;
- the GMT for the reference vaccine is within the limits of the control chart;
- the variability of the antibody responses meets the pre-defined criteria.

GMU assay

The antibody titres in the sera of mice or guinea-pigs immunised with the internal control and test vaccine are determined for each acellular pertussis antigen using the reference antiserum, and the GMTs are calculated for each antigen.

The GMU assay is not valid unless:

- the number of responder animals for the test vaccine and internal control meets the pre-defined criteria;
- the GMT for the internal control is within the limits of the control chart;
- the variability of the antibody responses meets the pre-defined criteria.

GLOSSARY

Internal control for GMU assay

A batch of vaccine shown to be representative of the current manufacturing process and whose response in mice or guinea pigs has been appropriately measured. The stability of the internal control shall be monitored and documented.

Reference vaccine for relative potency assay

A batch of vaccine shown to be effective in clinical trials or a batch representative thereof. The stability of the reference vaccine shall be monitored and documented.

Responder animals

Immunised animals producing antibodies at a titre greater than a threshold defined during the development and validation of the method.

The following section is published for information.

ASSAY OF PERTUSSIS VACCINE (ACELLULAR): GUIDELINES

METHOD B. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

The ELISA shown below is given as an example of an immunochemical method that has been found to be suitable.

Determination of antibody titre by ELISA method for pertussis toxin (PT), filamentous haemagglutinin (FHA), fimbrial agglutinogens (Fim 2/3) and pertactin (PRN)

2-fold dilutions of sera from test and reference vaccine or internal control are made on ELISA plates coated with

acellular pertussis antigens (PRN, PT, FHA or Fim 2/3). A guinea-pig reference antiserum and a negative guinea-pig serum are included on each plate. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG is added, followed by a peroxidase substrate.

Reagents and equipment:

— *ELISA plates*: 96 wells, columns 1-12, rows A-H.
— *Reference antiserum* (guinea-pig).
— *Peroxidase conjugate*. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.
— *Bordetella pertussis antigens* (PRN, PT, FHA or Fim 2/3).
— *Carbonate coating buffer pH 9.6*. Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 mL of *water R*. Distribute into 150 mL bottles and sterilise by autoclaving at 121 °C for 15 min.
— *Phosphate-buffered saline pH 7.4 (PBS)*. Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 mL of *water R*. Store at room temperature to prevent crystallisation. Dilute 10-fold with *water R* before use.
— *Citric acid solution*. Dissolve 10.51 g of *citric acid monohydrate R* in 1000 mL of *water R* and adjust to pH 4.0 with a 400 g/L solution of *sodium hydroxide R*.
— *Washing buffer*. PBS containing 0.5 g/L of *polysorbate 20 R*.
— *Diluent block buffer*. PBS containing 0.5 g/L of *polysorbate 20 R* and 25 g/L of dried skimmed milk.
— *Peroxidase substrate*. Shortly before use, dissolve 10 mg of *diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonate) R* (ABTS) in 20 mL of the citric acid solution. Immediately before use add 5 µL of *strong hydrogen peroxide solution R*.

Method

The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are used for negative control serum. Wells 2-12 A-H are used for guinea-pig reference antiserum (usually in 2 positions) and individual sera from guinea-pigs immunised with the test vaccine, or either the reference vaccine or the internal control.

Coat each well of the ELISA plates with 100 µL of the appropriate antigen solution (PT, FHA and Fim 2/3 at 2 µg/mL and PRT at 4 µg/mL, in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with the washing buffer. Block the plates by addition of 150 µL of the diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with the washing buffer. Place 100 µL of the diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of individual test and reference vaccine or internal control serum samples, reference antiserum and negative control serum samples. Allocate the negative control serum to column 1, the reference antiserum to at least 2 other columns and individual test and reference vaccine or internal control sera to the remaining columns and add 100 µL of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make 2-fold serial dilutions from row B down the plate to row H, by transferring 100 µL from one well to the next. Discard 100 µL from the last row so that all wells contain 100 µL. Incubate at 37 °C for 2 h. Wash thoroughly with the washing buffer. Prepare a suitable dilution of the peroxidase conjugate in the diluent block buffer and add 100 µL to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with the washing buffer. Add 100 µL of the peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as the addition of substrate was made.

7. *In vivo* Assay of Poliomyelitis Vaccine (Inactivated)

(Ph. Eur. method 2.7.20)

The capacity of the vaccine to induce the formation of neutralising antibodies is determined *in vivo* by one of the following methods.

TEST IN CHICKS OR GUINEA-PIGS

Prepare a suitable series of not fewer than 3 dilutions of the vaccine to be examined using a suitable buffered saline solution. Distribute either guinea-pigs weighing 250-350 g or 3-week-old chicks into groups of 10, and allocate a group to each dilution of the vaccine. Inject intramuscularly into each animal 0.5 mL of the dilution intended for its group. Bleed the animals after 5-6 days and separate the sera. Examine the sera for the presence of neutralising antibodies, at a dilution of 1 in 4, to each of the human poliovirus types 1, 2 and 3. Mix 100 $CCID_{50}$ of virus with the dilution of serum and incubate at 37 °C for 4.5-6 h. Keep at 5 ± 3 °C for 12-18 h where necessary for consistency of results. Inoculate the mixtures into cell cultures for the detection of unneutralised virus and read the results up to 7 days after inoculation. For each group of animals, note the number of sera that have neutralising antibodies and calculate the dilution of the vaccine that gives an antibody response in 50 per cent of the animals. Carry out in parallel a control test using a suitable reference preparation. The vaccine complies with the test if a dilution of 1 to 100 or more produces an antibody response for each of the 3 types of virus in 50 per cent of the animals.

TEST IN RATS

A suitable *in vivo* assay method consists of intramuscular injection into the hind limb(s) of not fewer than 3 dilutions of the vaccine to be examined and a reference vaccine, using for each dilution a group of 10 specific pathogen-free rats of a suitable strain. Use of 4 dilutions is often necessary to obtain valid results for all 3 serotypes. The number of animals per group must be sufficient to obtain results that meet the validity criteria; groups of 10 rats are usually sufficient, although valid results may be obtained with fewer animals per group. If animals of different sex are used, males and females are evenly distributed between all groups.
A weight range of 175-250 g has been found to be suitable. An inoculum of 0.5 mL per rat is used. The dose range is chosen such that a dose response to all 3 poliovirus types is obtained. Bleed the animals after 20-22 days. Neutralising titres against all 3 poliovirus types are measured separately using 100 $CCID_{50}$ of the Sabin strains as challenge viruses, Vero or Hep2 as indicator cells, and neutralisation conditions of 3 h at 35-37 °C followed by 18 h at 2-8 °C where necessary for consistency of results. Results are read following fixation and staining after 7 days of incubation at 35 °C.
For a valid antibody assay, the titre of each challenge virus must be shown to be within the range 10 $CCID_{50}$ to 1000 $CCID_{50}$ and the neutralising antibody titre of a control serum must be within 2 twofold dilutions of the geometric mean titre of the serum. The potency is calculated by comparison of the proportion of responders for the vaccine to

be examined and the reference vaccine by the probit method or, after validation, using a parallel-line model. For the probit method it is necessary to establish a cut-off neutralising antibody titre for each poliovirus type to define a responder. Due to interlaboratory variation, it is not possible to define cut-off values that could be applied by all laboratories. Rather, the cut-off values are determined for each laboratory based on a minimum series of 3 tests with the reference vaccine. The mid-point on a $\log_2$ scale of the minimum and maximum geometric mean titres of the series of 3 or more tests is used as the cut-off value. For each of the 3 poliovirus types, the potency of the vaccine is not significantly less than that of the reference preparation. The test is not valid unless:
- for both the vaccine to be examined and the reference vaccine, the ED_{50} lies between the smallest and the largest doses given to the animals;
- the statistical analysis shows no significant deviation from linearity or parallelism;
- the confidence limits ($P = 0.95$) are not less than 25 per cent and not more than 400 per cent of the estimated potency.

The following section is published for information.

GUIDELINE ON WAIVING OF THE *IN VIVO* ASSAY OF POLIOMYELITIS VACCINE (INACTIVATED) AND ITS COMBINATIONS

This guideline applies to vaccines derived from wild strains of poliovirus. The validation described should be carried out for each product before waiving of the in vivo assay, and should be repeated wherever there is a substantial change to the manufacturing process that may affect the in vitro or in vivo assays.

The European convention on the protection of vertebrate animals used for experimental and other scientific purposes requires that tests in animals shall not be carried out if a scientifically satisfactory alternative is reasonably and practically available. The aim of this guideline is therefore to promote waiving of the *in vivo* assay wherever it can be shown for a given product that the *in vitro* assay (D-antigen determination) gives sufficient assurance of satisfactory potency for routine batch control.

For the *in vivo* assay, the test in rats is considered to be the method of choice. For vaccines that are assayed using chicks or guinea-pigs and that have an established record of production history, the *in vivo* assay may be waived if the rat assay is also applied to the batches included in the validation study described below. For vaccines not yet approved, the results of the rat assay on all final bulks should be included in all data generated for demonstration of consistency of production before waiving of the *in vivo* assay.

Once the *in vivo* assay has been waived, batches of vaccine will be released on the basis of the *in vitro* assay, and the *in vivo* assay should not be used as an alternative for the release of a batch that fails the *in vitro* assay. Repetition of the *in vitro* assay may be performed according to an authorised procedure.

PROCEDURE

The following conditions should be met before performance of the validation study:
- appropriate experience of the rat assay;
- full validation of the D-antigen assay (linearity, repeatability, intermediate precision, accuracy and limits of quantification);
- establishment of acceptance criteria for the D-antigen assay based on a suitable number of consecutive final lots;
- establishment of production consistency on recent final bulks using the currently approved *in vivo* assay; the final bulks should correspond to the final lots used to establish the acceptance criteria for the D-antigen assay and should represent different inactivated harvests of each of the 3 types of poliovirus.

The validation study should be performed on:
- a final bulk/lot that is representative of the current production method;
- 2 sub-potent batches prepared, for example, by heating normal vaccine or mixing it with heat-treated vaccine; the sub-potent batches should have expected titres of about half that of the representative final bulk/lot.

These batches are assayed using as reference standard a homologous production batch:
- by the currently approved *in vivo* assay for the vaccine;
- by the rat assay where this is not the currently approved *in vivo* assay;
- by the D-antigen assay.

Waiving of the *in vivo* assay is acceptable if the representative final bulk/lot complies with the *in vivo* and *in vitro* assays and the sub-potent batches fail to comply. If a sub-potent batch fails to comply with the D-antigen assay but complies with the *in vivo* assay, the latter may be repeated.

8. Flocculation Value (Lf) of Diphtheria and Tetanus Toxins and Toxoids (Ramon Assay)

(Ph. Eur. method 2.7.27)

The content of toxin or toxoid in a sample can be expressed as a flocculation value (Lf) using the Ramon assay. In this assay, antitoxin is added in increasing concentrations to a series of tubes containing a constant amount of toxin or toxoid. At the equivalence point of toxin/toxoid and antitoxin, flocculation occurs in 1 or more tubes. The first tube in which flocculation occurs is used to determine the Lf value of the sample.

The Lf value of a toxin or toxoid is determined by the number of units of antitoxin that, when mixed with the sample, produces an optimally flocculating mixture (Ramon assay).

Practical experience has shown that the results of the calibration of antitoxins in International Units (IU), for example by comparison to international antitoxin standards, depends on the immunochemical method used. For this reason, antitoxins used for the Ramon assay must be directly calibrated against the *international biological reference reagents for diphtheria or tetanus toxoid for flocculation tests*, using the principles described below. The concentration thus determined may be indicated in Lf-equivalents per millilitre (Lf-eq./mL).

By definition, 1 Lf is the quantity of toxin or toxoid that flocculates in the shortest time with 1 Lf-eq. of specific antitoxin.

A range of volumes of the reference standard of antitoxin adjusted to a concentration of 100 Lf-eq./mL is dispensed into a series of, for example, 7 cm × 1 cm flocculation tubes. A sufficient quantity of a 9 g/L solution of *sodium chloride R* is added to each tube to give a constant total volume of, for example, 1 mL. The test sample is diluted to give an expected concentration of approximately 50 Lf/mL, and, for example, 1 mL aliquots of this dilution are dispensed into each of the tubes containing antitoxin. The tubes are properly mixed by shaking, then placed in a

water-bath at a constant temperature between 30 °C and 52 °C, and observed at regular intervals for the first appearance of floccules. This may require the use of a magnifying lens and strong illumination.

The first and the second mixtures to flocculate are recorded as well as the time taken for the first flocculation to appear. 2 tubes may flocculate simultaneously.

The first tube to flocculate is the one that contains the amount of antitoxin closest in equivalence to the amount of antigen in the sample. The antitoxin content of this tube can be used to calculate the Lf value of the sample. If 2 tubes flocculate at the same time, the mean from the tubes are given as the result.

The time taken for the first tube to flocculate (Kf) is a useful indicator of the quality of the antigen. If at a given temperature and concentration of toxoid and antitoxin the Kf value is increased compared with normal, this indicates that the antigen has been damaged. The Kf value may also change with the quality of the antitoxin used.

Example

Tube	A	B	C	D	E	F
Antitoxin added (Lf-eq.)	40	45	50	55	60	65
Antitoxin added (mL)	0.40	0.45	0.50	0.55	0.60	0.65
Saline added (mL)	0.60	0.55	0.50	0.45	0.40	0.35
Diluted sample added	1.0	1.0	1.0	1.0	1.0	1.0

If in this example the first tube to flocculate is tube C then the Lf value of the diluted sample is 50 Lf/mL. However, if the first tube to flocculate is tube A or tube F this does not indicate equivalence at that level. It would be necessary to perform a repeat test using either a different dilution of test sample or selecting a different range of doses of reference antitoxin.

More precision can be obtained by making allowance for the sequence of flocculation after the first tube. Thus, in the example quoted, if the second tube to flocculate had been tube D, the final value for the diluted sample would be 52, whereas if the second tube to flocculate was tube B, the final value would be 48. The test may be performed in duplicate with slightly different dilutions of the test sample.

If there is no indication of the expected Lf value of the sample available, it is advisable to obtain a rough estimate by use of a wider range of antitoxin content in the tubes before proceeding to the final test.

Example

Tube	A	B	C	D	E	F
Antitoxin content (Lf-eq.)	20	30	45	70	100	150

The level of toxin or toxoid and antitoxin concentration in the test may be varied, but this will markedly affect the flocculation time, so that at very low levels the test will take too long, whilst at a high concentration the onset of flocculation may be so rapid as to make it difficult to distinguish the first and second tubes to flocculate.

Assay of low concentrations by blend flocculation

For very low concentrations, it is preferable to measure toxin or toxoid by the method of blend flocculation. This involves comparison of the Lf value of a known toxin or toxoid and that of a mixture of the sample with that toxin or toxoid.

When a toxin or toxoid with a known Lf value and a toxin or toxoid with an unknown Lf value are flocculated together, the mixture will flocculate as the sum of their values if they are homogeneous. If non-homogenous toxins or toxoids are mixed they will produce an aberrant pattern with 2 flocculation maxima.

9. Residual Pertussis Toxin

(Ph. Eur. method 2.6.33)

The test for residual pertussis toxin is performed *in vitro*, using a Chinese Hamster Ovary (CHO) cell-based assay, and is intended for the assay of non-adsorbed purified pertussis components.

Pertussis toxin BRP is suitable as a reference pertussis toxin preparation.

The CHO cell-clustering assay (CHO assay) is based on the induction of clusters in non-confluent CHO cell cultures by active pertussis toxin. The cultures are then examined under a microscope and any clusters present are counted. The assay may be used as a quantitative test or as a limit test with the sensitivity determined within each assay using dilutions of a reference pertussis toxin preparation.

The sensitivity of the CHO assay to pertussis toxin is verified with *pertussis toxin BRP* or a suitable reference preparation calibrated in International Units using a suitable CHO assay. The assay sensitivity is defined as the lowest concentration in the reference preparation dilution series to produce a positive response, i.e. at least 10 CHO cell clusters. A suitable assay has a sensitivity of at least 5 mIU/mL.

The following method is given as an example.

Reagents and equipment

— *Pertussis toxin BRP.*
— *CHO-K1 cell line* (ATCC No. CCL-61 or ECACC No. 85051005).
— *Kaighn's modified Ham's F-12K medium.*

Media that have a slightly different composition from that in Table 2.6.33.-1 may also be used. Proline is an essential component of the medium. Adjust to pH 7.2 ± 0.2 if necessary.

Table 2.6.33.-1. – *Kaighn's modified Ham's F-12K medium*

Amino acids	
L-Alanine	18.0 mg
L-Arginine hydrochloride	0.4220 g
L-Asparagine monohydrate	30.0 mg
L-Aspartic acid	26.6 mg
L-Cysteine hydrochloride monohydrate	70.0 mg
L-Glutamic acid	29.0 mg
L-Glutamine	0.2920 g
Glycine	15.0 mg
L-Histidine hydrochloride monohydrate	45.8 mg
L-Isoleucine	7.88 mg
L-Leucine	26.2 mg
L-Lysine hydrochloride	73.0 mg

Amino acids	
L-Methionine	8.96 mg
L-Phenylalanine	9.92 mg
L-Proline	69.0 mg
L-Serine	21.0 mg
L-Threonine	23.0 mg
L-Tryptophan	4.1 mg
L-Tyrosine disodium salt dihydrate	13.5 mg
L-Valine	23.0 mg
Vitamins	
Biotin	70 µg
D-Calcium pantothenate	0.5 mg
Choline chloride	14.0 mg
Folic acid	1.3 mg
myo-Inositol	18.0 mg
Nicotinamide	37 µg
Pyridoxine hydrochloride	60 µg
Riboflavin	40 µg
Thiamine hydrochloride	0.3 mg
Vitamin B12	1.4 mg
Inorganic salts	
Calcium chloride, anhydrous	0.1020 g
Cupric sulfate pentahydrate	2 µg
Disodium hydrogen phosphate, anhydrous	0.1155 g
Ferric sulfate heptahydrate	0.8 mg
Magnesium chloride, anhydrous	49.7 mg
Magnesium sulfate, anhydrous	0.1920 g
Potassium chloride	0.2850 g
Sodium bicarbonate	2.5000 g
Sodium chloride	7.5300 g
Zinc sulfate heptahydrate	0.144 mg
Other components	
D-Glucose	1.2600 g
Hypoxanthine sodium salt	4.0 mg
Lipoic acid	0.21 mg
Phenol red	3.0 mg
Putrescine dihydrochloride	0.32 mg
Sodium pyruvate	0.2200 g
Thymidine	0.7 mg
Water	to 1000 mL

— *CHO cell culture medium.* Supplement Kaighn's modified Ham's F-12K medium with foetal bovine serum to obtain a final concentration of 10 per cent *V/V*. Add a sufficient quantity of 0.2 M L-glutamine solution to obtain a final concentration of 1 per cent *V/V*. An antibiotic/antimycotic solution may be added if required. Adjust to pH 7.2 ± 0.2 if necessary. Store at 5 ± 3 °C for a maximum of 3 weeks, protected from light.

— *Trypsin-EDTA solution* (trypsin 0.25 per cent).

— *Phosphate-buffered saline pH 7.4 (PBS)*, without calcium or magnesium. Dissolve 9.0 g of *sodium chloride R*, 0.144 g of *potassium dihydrogen phosphate R* and 0.795 g of *disodium hydrogen phosphate heptahydrate R* in *water R*, and dilute to 1000.0 mL with the same solvent. Adjust the pH if necessary.

— *24-well flat-bottomed assay plates with lid.*

— *75 cm^2 tissue culture flasks.*

— *Low protein binding polypropylene microtubes.*

CHO cell culture

The cells are obtained from a cell bank and used between defined passage levels. CHO cells are cultured in tissue culture flasks containing 20 mL of CHO cell culture medium in a humidified incubator set at 37 °C and 5 per cent CO_2. The cells are passaged at a ratio of 1:5 to 1:20 as they approach confluence.

Before use, allow all reagents to reach room temperature or warm to 37 °C.

To passage the cells, remove the CHO cell culture medium. Wash the cell layer gently by rinsing briefly 2-3 times with PBS. Remove the PBS and add 2 mL of trypsin-EDTA solution to the flask, allowing it to cover the monolayer for 20 s. Remove the trypsin-EDTA solution by aspiration. Immediately observe the culture using phase-contrast microscopy. When the cells begin to contract, tap the side of the culture flask firmly to dislodge the cells. When the majority of cells are free-floating, add 10 mL of CHO cell culture medium to stop the trypsin digestion. Trypsinisation used for cell detachment must be carefully controlled to avoid over-digestion which causes cleavage of either pertussis toxin receptors or cell adherence proteins, or both.

Determine the cell concentration and viability using trypan blue exclusion or another appropriate method. The cell viability must be greater than 95 per cent to continue. Transfer a sufficient volume of the cell suspension to a fresh flask for a 1:5 to 1:20 passage ratio and add CHO cell culture medium to bring the volume to 20 mL. Incubate the cells in a humidified incubator set at 37 °C and 5 per cent CO_2 for at least 48 h prior to use in the CHO assay.

Seeding density for CHO assay

Prepare a suspension of CHO cells using the trypsinisation procedure described above. Count and dilute the cell suspension to between 4×10^4 and 8×10^4 CHO cells/mL in CHO cell culture medium. The cell concentration selected must allow clusters to be identified at the end of the stimulation period. Transfer 250 µL of the cell suspension into each well of the 24-well plates. Store the seeded plates in a humidified incubator set at 37 °C and 5 per cent CO_2 while the reference preparation and test sample are prepared.

Preparation of pertussis toxin reference

Reconstitute *pertussis toxin BRP* as stated in the leaflet accompanying the reference preparation. Prepare 7 two-fold serial dilutions in CHO cell culture medium, in such a way that the assay end-point occurs in the middle of the dilution series. The dilutions are prepared in low protein binding polypropylene microtubes. One dilution series for the reference preparation is included in each assay plate.

Preparation of non-adsorbed purified pertussis component samples

Dilute the test sample in CHO cell culture medium to obtain the highest concentration of the test sample which does not significantly dilute the nutrients of the medium, in order to maximise the sensitivity of the assay. Prepare a dilution series as described for the reference preparation.

Stimulation of CHO cells

Transfer 250 µL from each tube of the reference preparation dilution series into the assigned wells of the assay plates seeded with CHO cells. Similarly, transfer 250 µL of each dilution of the test sample into the assigned well(s). Transfer 250 µL of CHO cell culture medium into the negative control wells. Return the assay plates to a humidified incubator set at 37 °C and 5 per cent CO_2 for 48 h.

Scoring and interpretation of results

Observe the cell cultures using phase contrast microscopy at a magnification of 4× or 10×. In all wells the cell cultures must not be confluent and must have sufficient growth space to allow any clusters present to be counted. Assign a positive score when 10 or more CHO cell cluster formations are clearly evident within a single well. Assign a negative score to wells containing fewer than 10 clusters. The end-point concentration is the lowest concentration at which there is a positive score.

Assay validity

The test is not valid unless:

— the negative control wells show no evidence of clustering.
— wells containing the reference toxin preparation at a concentration greater than or equal to 5 mIU/mL exhibit a positive response (i.e. 10 or more CHO cell clusters).
— a clear end-point dilution is observed for the reference preparation.
— replicate values for the end-point of the reference preparation do not differ by more than one 2-fold dilution within one assay.

Calculation

Calculate the residual pertussis toxin activity in the test sample in International Units per millilitre, relative to the reference preparation, using the following expression:

$$\frac{GM(end-point)_S}{GM(end-point)_R} \times A_R$$

$GM(end\text{-}point)_S$ = geometric mean of the reciprocal of the end-point dilutions (last dilution at which there is a positive score) for the test sample;

$GM(end\text{-}point)_R$ = geometric mean of the reciprocal of the end-point dilutions (last dilution at which there is a positive score) for the reference preparation;

A_R = activity of the reference preparation (stock solution), in International Units per millilitre.

Example

Series of 7 two-fold dilutions were prepared for the reference preparation and test sample. In this example, the reference stock solution has an activity of 1000 IU/mL. The scores observed at each dilution of the reference preparation and test sample, the reciprocal end-point dilutions and the geometric means of reciprocal end-point dilutions are shown in Tables 2.6.33.-2 and 2.6.33.-3.

Table 2.6.33.-2 – *Reference preparation dilutions and scores*

Reference preparation dilution	Score	
	Rep. 1	Rep. 2
1:100 000	+	+
1:200 000	+	+
1:400 000	+	+
1:800 000	+	-
1:1 600 000	-	-
1:3 200 000	-	-
1:6 400 000	-	-
End-point dilutions	1:800 000	1:400 000
Reciprocal of end-point dilutions	800 000	400 000
$GM(end\text{-}point)_R$	565 685	

Table 2.6.33.-3 – *Test sample dilutions and scores*

Test sample dilution	Score	
	Rep. 1	Rep. 2
1:100	+	+
1:200	+	+
1:400	+	+
1:800	+	+
1:1600	+	-
1:3200	-	-
1:6400	-	-
End-point dilutions	1:1600	1:800
Reciprocal of end-point dilutions	1600	800
$GM(end\text{-}point)_S$	1131	

The residual pertussis toxin activity in the test sample can be determined as follows: (1131/565685) × 1000 = 2 IU/mL.

L. Nucleic Acid Amplification Techniques

(Ph. Eur. method 2.6.21)

1. INTRODUCTION

Nucleic acid amplification techniques are based on 2 different approaches:

1. amplification of a target nucleic acid sequence using, for example, polymerase chain reaction (PCR), ligase chain reaction (LCR), or isothermal ribonucleic acid (RNA) amplification;

2. amplification of a hybridisation signal using, for example, for deoxyribonucleic acid (DNA), the branched DNA (bDNA) method; in this case signal amplification is achieved without subjecting the nucleic acid to repetitive cycles of amplification.

In this general chapter, the PCR method is described as the reference technique. Alternative methods may be used, if they comply with the quality requirements described below.

2. SCOPE

This section establishes the requirements for sample preparation, *in vitro* amplification of DNA sequences and detection of the specific PCR product. With the aid of PCR, defined DNA sequences can be detected. RNA sequences can also be detected following reverse transcription of the RNA to complementary DNA (cDNA) and subsequent amplification.

3. PRINCIPLE OF THE METHOD

PCR is a procedure that allows specific *in vitro* amplification of segments of DNA or of RNA after reverse transcription into cDNA.

Following denaturation of double-stranded DNA into single-stranded DNA, 2 synthetic oligonucleotide primers of opposite polarity anneal to their respective complementary sequences in the DNA to be amplified. The short double-stranded regions that form as a result of specific base pairing between the primers and the complementary DNA sequence border the DNA segment to be amplified, and serve as starting positions for *in vitro* DNA synthesis by means of a heat-stable DNA polymerase.

Amplification of the DNA occurs in cycles consisting of:
- heat denaturation of the nucleic acid (target sequence) into 2 single strands;
- specific annealing of the primers to the target sequence under suitable reaction conditions;
- extension of the primers, which are bound to both single strands, by DNA polymerase at a suitable temperature (DNA synthesis).

Repeated cycles of heat denaturation, primer annealing and DNA synthesis results in an exponential amplification of the DNA segment limited by the primers.

The specific PCR product known as an amplicon can be detected by a variety of methods of appropriate specificity and sensitivity.

Multiplex PCR assays use several primer pairs designed for simultaneous amplification of different targets in one reaction.

4. TEST MATERIAL

Because of the high sensitivity of PCR, the samples must be protected against external contamination with target sequences. Sampling, storage and transport of the test material are performed under conditions that minimise degradation of the target sequence. In the case of RNA target sequences, special precautions are necessary since RNA is highly sensitive to degradation by ribonucleases. Care must be taken since some added reagents, such as anticoagulants or preservatives, may interfere with the test procedure.

5. TEST METHOD

5.1. Prevention of contamination

The risk of contamination requires a strict segregation of the areas depending on the material handled and the technology used. Points to consider include movement of personnel, gowning, material flow and air supply and decontamination procedures.

The system should be sub-divided into compartments such as:
- master-mix area (area where exclusively template-free material is handled, e.g. primers, buffers, etc.);
- pre-PCR (area where reagents, samples and controls are handled);
- PCR amplification (amplified material is handled in a closed system);
- post-PCR detection (the only area where the amplified material is handled in an open system).

If closed systems are used, the strict segregation of areas is not required.

5.2. Sample preparation

When preparing samples, the target sequence to be amplified needs to be efficiently extracted or liberated from the test material in a reproducible manner and in such a way that amplification under the selected reaction conditions is possible. A variety of physico-chemical extraction procedures and/or enrichment procedures may be employed.

Additives present in test material may interfere with PCR. The procedures described under 7.3.2. must be used as a control for the presence of inhibitors originating from the test material.

In the case of RNA-templates, care must be taken to avoid ribonuclease activity.

5.3. Amplification

PCR amplification of the target sequence is conducted under defined cycling conditions (temperature profile for denaturation of double-stranded DNA, annealing and extension of primers; incubation times at selected temperatures; ramp rates). These depend on various parameters such as:
- the length and base composition of primer and target sequences;
- the type of DNA polymerase, buffer composition and reaction volume used for the amplification;
- the type of thermocycler used and the thermal conductivity rate between the apparatus, reaction tube and reaction fluid.

5.4. Detection

The amplicon generated by PCR may be identified by size, sequence, chemical modification or a combination of these parameters. Detection and characterisation by size may be achieved by gel electrophoresis (using agarose or polyacrylamide slab gels or capillary electrophoresis) or column chromatography (for example, liquid chromatography). Detection and characterisation by sequence composition may be achieved by the specific hybridisation of probes having a sequence complementary to the target sequence or by cleavage of the amplified material reflecting target-specific restriction-enzyme sites. Detection and characterisation by chemical modification may be achieved by, for example, incorporation of a fluorophore into the amplicons and subsequent detection of fluorescence following excitation.

Detection of amplicons may also be achieved by using probes labelled to permit a subsequent chemiluminescent, radioisotopic or immuno-enzyme-coupled detection.

6. EVALUATION AND INTERPRETATION OF RESULTS

A valid result is obtained within a test only if the positive control(s) is unambiguously positive and the negative control(s) is unambiguously negative. Due to the very high sensitivity of the PCR method and the inherent risk of contamination, it is necessary to confirm positive results by repeating the complete test procedure in duplicate, where possible on a new aliquot of the sample. The sample is considered positive if at least one of the repeat tests gives a positive result. As soon as a measurable target threshold is defined, a quantitative test system is required.

7. QUALITY ASSURANCE

7.1. Validation of the PCR assay system

The validation programme must include validation of instrumentation and the PCR method employed. Reference should be made to the ICH guideline Q2(R1) Validation of Analytical Procedures: Text and Methodology.

Appropriate official working reference preparations or in-house reference preparations calibrated against International Standards for the target sequences are used for validation of a PCR test, when available.

7.1.1. Determination of the positive cut-off point

During validation of qualitative tests, the positive cut-off point must be determined. The positive cut-off point is defined as the minimum number of target sequences per volume sample that can be detected in 95 per cent of test runs. The positive cut-off point depends on interrelated factors such as the volume of the sample extracted and the efficacy of the extraction methodology, the transcription of the target RNA into cDNA, the amplification process and the detection.

To define the detection limit of the assay system, reference must be made to the positive cut-off point for each target sequence and the test performance above and below the positive cut-off point.

7.1.2. Quantitative assay systems

For a quantitative assay, the following parameters are determined during validation: accuracy, precision, specificity, quantitation limit, linearity, range and robustness.

7.2. Quality control of reagents

All reagents crucial for the methodology used have to be controlled prior to use in routine applications. Their acceptance/withdrawal is based on pre-defined quality criteria.

Primers are a crucial component of the PCR assay and as such their design, their purity and the validation of their use in a PCR assay require careful attention. Primers may be modified (for example, by conjugation with a fluorophore or antigen) in order to permit a specific method of detection of the amplicon, provided such modifications do not inhibit accurate and efficient amplification of the target sequence.

7.3. Run controls

7.3.1. External controls

In order to minimise the risk of contamination and to ensure adequate sensitivity, the following external controls are included in each PCR assay:

— positive control: this contains a defined number of target-sequence copies, the number being close to the positive cut-off value, and determined individually for each assay system and indicated as a multiple of the positive cut-off value of the assay system;

— negative control: a sample of a suitable matrix already proven to be free of the target sequences.

7.3.2. Internal control

Internal controls are defined nucleic acid sequences containing, unless otherwise prescribed, the primer binding sites. Internal controls must be amplified with defined efficacy, and the amplicons must be clearly discernible. Internal controls must be of the same type of nucleic acid (DNA/RNA) as the material to be tested. The internal control is preferably added to the test material before isolating the nucleic acid and therefore acts as an overall control (extraction, reverse transcription, amplification, detection).

7.3.3. Threshold control

The threshold control for quantitative assays is a test sample with the analyte at a concentration that is defined as the threshold not to be exceeded. It contains the analyte suitably calibrated in International Units and is analysed in parallel in each run of a quantitative assay.

7.4. External quality assessment

Participation in external quality assessment programmes is an important PCR quality assurance procedure for each laboratory and each operator.

The following sections are published for information.

VALIDATION OF NUCLEIC ACID AMPLIFICATION TECHNIQUES (NAT) FOR THE DETECTION OF HEPATITIS C VIRUS (HCV) RNA IN PLASMA POOLS: GUIDELINES

1. SCOPE

The majority of nucleic acid amplification analytical procedures are qualitative (quantal) tests for the presence of nucleic acid with some quantitative tests (either in-house or commercial) being available. For the detection of HCV RNA contamination of plasma pools, qualitative tests are adequate and may be considered to be a limit test for the control of impurities as described in the *Pharmeuropa* Technical Guide for the elaboration of monographs, December 1999, Chapter III 'Validation of analytical procedures'. These guidelines describe methods to validate only qualitative nucleic acid amplification analytical procedures for assessing HCV RNA contamination of plasma pools. Therefore, the 2 characteristics regarded as the most important for validation of the analytical procedure are the specificity and the detection limit. In addition, the robustness of the analytical procedure should be evaluated.

However, this document may also be used as a basis for the validation of nucleic acid amplification in general.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part or all of the analytical procedure, documented validation points already covered by the kit manufacturer can substitute for the validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. detection limit, robustness, cross-contamination).

2. SPECIFICITY

Specificity is the ability to assess unequivocally nucleic acid in the presence of components that may be expected to be present.

The specificity of nucleic acid amplification analytical procedures is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and the detection steps).

When designing primers and probes, the specificity of the primers and probes to detect only HCV RNA should be investigated by comparing the chosen sequences with sequences in published data banks. For HCV, primers (and probes) will normally be chosen from areas of the 5' non-coding region of the HCV genome which are highly conserved for all genotypes.

The amplified product should be unequivocally identified by using one of a number of methods such as amplification with nested primers, restriction enzyme analysis, sequencing, or hybridisation with a specific probe.

In order to validate the specificity of the analytical procedure, at least 100 HCV RNA-negative plasma pools should be tested and shown to be non-reactive. Suitable samples of non-reactive pools are available from the European Directorate for the Quality of Medicines & HealthCare (EDQM).

The ability of the analytical procedure to detect all HCV genotypes will again depend on the choice of primers, probes and method parameters. This ability should be demonstrated using characterised reference panels. However, in view of the difficulty in obtaining samples of some genotypes (e.g. genotype 6), the most prevalent genotypes (e.g. genotypes 1 and 3 in Europe) should be detected at a suitable level.

3. DETECTION LIMIT

The detection limit of an individual analytical procedure is the lowest amount of nucleic acid in a sample that can be detected but not necessarily quantitated as an exact value.

The nucleic acid amplification analytical procedure used for the detection of HCV RNA in plasma pools usually yields qualitative results. The number of possible results is limited to 2: either positive or negative. Although the determination of the detection limit is recommended, for practical purposes, a positive cut-off point should be determined for the nucleic acid amplification analytical procedure. The positive cut-off point (as defined in the general chapter 2.6.21) is the minimum number of target sequences per volume sample that can be detected in 95 per cent of test runs. This positive cut-off point is influenced by the distribution of viral genomes in the individual samples being tested and by factors such as enzyme efficiency, and can result in different 95 per cent cut-off values for individual analytical test runs.

In order to determine the positive cut-off point, a dilution series of a working reagent or of the *hepatitis C virus BRP*, which has been calibrated against the WHO HCV International Standard, should be tested on different days to examine variation between test runs. At least 3 independent dilution series should be tested with a sufficient number of replicates at each dilution to give a total number of 24 test results for each dilution, to enable a statistical analysis of the results.

For example, a laboratory could test 3 dilution series on different days with 8 replicates for each dilution, 4 dilution series on different days with 6 replicates for each dilution, or 6 dilution series on different days with 4 replicates for each dilution. In order to keep the number of dilutions at a manageable level, a preliminary test (using, for example, $\log_{10}$ dilutions of the plasma pool sample) should be carried out in order to obtain a preliminary value for the positive cut-off point (i.e. the highest dilution giving a positive signal). The range of dilutions can then be chosen around the predetermined preliminary cut-off point (using, for example, a dilution factor of 0.5 $\log_{10}$ or less and a negative plasma pool for the dilution matrix). The concentration of HCV RNA that can be detected in 95 per cent of test runs can then be calculated using an appropriate statistical evaluation.

These results may also serve to demonstrate the intra-assay variation and the day-to-day variation of the analytical procedure.

4. ROBUSTNESS

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage.

The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. However, the robustness of the method can be demonstrated during its development when small variations in the concentrations of reagents (e.g. $MgCl_2$, primers or dNTP) are tested. To demonstrate robustness, at least 20 HCV RNA negative plasma pools (selected at random) spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value should be tested and found positive.

Problems with robustness may also arise with methods that use an initial ultracentrifugation step prior to extraction of the viral RNA. Therefore, to test the robustness of such methods, at least 20 plasma pools containing varying levels of HCV RNA, but lacking HCV-specific antibodies, should be tested and found positive.

Cross-contamination prevention should be demonstrated by the accurate detection of a panel of at least 20 samples consisting of alternate samples of negative plasma pools and negative plasma pools spiked with high concentrations of HCV (at least 10^2 times the 95 per cent cut-off value or at least 10^4 IU/mL).

5. QUALITY ASSURANCE

For biological tests such as NAT, specific problems may arise that influence both the validation and the interpretation of results. The test procedures must be described precisely in the form of standard operating procedures (SOPs). These should cover:

- the mode of sampling (type of container, etc.);
- the preparation of mini-pools (where appropriate);
- the conditions of storage before analysis;
- the exact description of the test conditions, including precautions taken to prevent cross-contamination or destruction of the viral RNA, reagents and reference preparations used;
- the exact description of the apparatus used;
- the detailed formulae for calculation of results, including statistical evaluation.

The use of a suitable run control (for example, an appropriate dilution of *hepatitis C virus BRP* or plasma spiked with an HCV sample calibrated against the WHO HCV International Standard) can be considered a satisfactory system-suitability check and ensures that the reliability of the analytical procedure is maintained whenever used.

Technical qualification An appropriate installation and operation qualification programme should be implemented for each critical piece of the equipment used.

For confirmation of analytical procedure performance after a change of critical equipment (e.g. thermocyclers), the change should be documented by conducting a parallel test on 8 samples of a plasma pool that is spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value. All results should be positive.

Operator qualification An appropriate qualification programme should be implemented for each operator involved in the testing.

VALIDATION OF NUCLEIC ACID AMPLIFICATION TECHNIQUES (NAT) FOR THE QUANTIFICATION OF B19 VIRUS (B19V) DNA IN PLASMA POOLS: GUIDELINES

1. SCOPE

The European Pharmacopoeia requires that plasma pools used for manufacture of certain products are tested for the presence of B19 virus (B19V) DNA with a threshold concentration that must not be exceeded. In order to comply with these requirements, quantitative NAT tests are preferred. The characteristics regarded as the most important for validation of the quantitative NAT procedure are accuracy, precision, specificity, quantitation limit, linearity and range. In addition, the robustness of the analytical procedure should be evaluated.

This guideline describes methods to validate NAT analytical procedures for assessing B19V DNA contamination of plasma pools based on the ICH guidelines. However, this document may also be used as a basis for the validation of quantitative NAT in general.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part or all of the analytical procedure, documented validation points already covered by the kit manufacturer can substitute for the validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. precision, accuracy, range, robustness).

2. ACCURACY

Accuracy expresses the closeness of agreement between the value that is accepted as either a conventional true value or an accepted reference value and the value found.
The accuracy of an assay is dependent on the calibration of the assay and on the variance of the different assay steps. Though it is recommended to establish the accuracy across the specified range of the analytical procedure, the most important assessment of accuracy is in the range of the threshold concentration. In the case of B19V NAT assays for investigation of plasma pools it is recommended to assess the accuracy of the calibrated assay by assaying at least 5 concentrations (dilution factor of 0.5 $\log_{10}$) of *B19 virus DNA for NAT testing BRP* or another material, suitably calibrated in International Units against the actual WHO B19 DNA International Standard, covering the range of the currently recommended threshold concentration of 10.0 IU/µL B19V DNA (e.g. 10^5 IU/mL, $10^{4.5}$ IU/mL, 10^4 IU/mL, $10^{3.5}$ IU/mL and 10^3 IU/mL), with at least 3 replicates for each dilution. Accuracy should be reported for the different concentrations in terms of percentage determined compared with the known amount of B19V DNA. It should reflect the level of technology of the respective assays, which should also be defined, for example in collaborative studies.

3. PRECISION

Precision expresses the closeness of agreement between a series of measurements, obtained from multiple sampling of the same homogenous sample. The precision is defined at 3 levels:

- repeatability expresses the precision under the same operating conditions over a short interval of time (intra-assay precision); it is assessed by using 1 assay and testing 3 replicates of appropriate dilutions of a B19V DNA-positive sample suitably calibrated in International Units and covering the whole quantitative range of the assay; the coefficient of variation for the individual samples is calculated (intra-assay variability);
- intermediate precision expresses the intra-laboratory variations (inter-assay precision); it is established by assaying replicates (as routinely used for the assay) of appropriate dilutions of a B19V DNA-positive sample suitably calibrated in International Units covering the whole quantitative range of the assay under different circumstances (e.g. different days, different analysts, different equipment, different reagents); the coefficient of variation for the individual samples is calculated;
- reproducibility expresses the precision between different laboratories (inter-laboratory precision); it is assessed by participation in quantitative collaborative studies on B19V DNA-NAT assays, e.g. under the Proficiency Testing Scheme (PTS), including the comparative analysis of the obtained quantitative results, where appropriate.

4. SPECIFICITY

Specificity expresses the ability to assess unequivocally nucleic acid in the presence of components that may be expected to be present. The specificity of NAT analytical procedures is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and the detection steps).

When designing primers and probes, the specificity of the primers and probes to detect only human B19V DNA should be investigated by comparing the chosen sequences with sequences in published data banks. There should be no major homology found with sequences unrelated to B19V.

The amplified product should be unequivocally identified by using one of a number of methods such as amplification with nested primers, restriction enzyme analysis, sequencing, or hybridisation with a specific probe.

In order to examine the specificity of the analytical procedure, at least 20 B19V DNA-negative plasma pools should be tested and shown to be non-reactive.

Parvovirus B19 genotypes The International Committee on Taxonomy of Viruses (ICTV) has classified representatives of the 3 genotypes as strains of human parvovirus B19. Genotype 1 represents prototype B19V, genotype 2 represents viral sequences like A6, and genotype 3 represents V9-like sequences. By performing sequence alignment with respective B19V genotype sequences available from nucleic acid sequence databases, primers and probes should be designed to detect and quantify consistently the different human parvovirus B19 genotypes. Reference materials should be used to check the approach chosen. Since biological reference preparations reflecting some genotypes might be difficult to obtain, respective plasmid preparations or synthetic nucleic acids may also serve as a characterised target sequence source. However, those cannot be used to validate the extraction procedure.

5. QUANTITATION LIMIT

The quantitation limit is the lowest amount of nucleic acid in a sample that can be determined quantitatively with suitable precision and accuracy. The quantitation limit of the B19V NAT assay is assessed during the repeatability and intermediate-precision studies by limiting dilution analysis. The lowest concentration of target nucleic acids that is quantitated with suitable precision and accuracy is defined.

6. LINEARITY

The linearity of an assay is its ability to obtain test results that are directly proportional to the concentration of the nucleic acid. The linearity of the B19V NAT assay is assessed during the repeatability and intermediate-precision studies by testing replicates of diluted samples with the concentrations covering the whole quantitative range. The interval between the upper and the lower concentration of the target nucleic acid where test results are directly proportional to the concentrations is defined.

7. RANGE

The range of an assay is the interval between the upper and the lower concentration of nucleic acid in the sample for which it has been demonstrated that the procedure has a suitable level of precision, accuracy and linearity. The range of the B19V NAT assay is assessed during the repeatability and intermediate-precision studies by testing replicates of diluted samples. The interval between the upper and the lower concentration that can be expressed with an acceptable degree of accuracy and precision is defined.

8. ROBUSTNESS

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage. The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. Nonetheless, the robustness of NAT can be demonstrated during the development of the method when small variations in the concentrations of reagents, for example $MgCl_2$, primers or dNTP, are tested. To demonstrate robustness, at least 20 B19V DNA-negative plasma pool samples spiked with B19V DNA at the threshold concentration should be tested and found to have acceptable quantitative values.

Cross-contamination prevention should be demonstrated by the accurate detection of a panel of at least 20 samples consisting of alternate samples of plasma pools without B19V DNA or with levels below the threshold concentration (10 samples) and plasma pools spiked with high concentrations of B19V DNA (at least 10^2 times the threshold level, 10 samples).

9. QUALITY ASSURANCE

For biological tests such as NAT, specific problems may arise that may influence both the validation and the interpretation of results. The test procedures must be described precisely in the form of standard operating procedures (SOPs). These should cover:

- the mode of sampling (type of container, etc.);
- the preparation of mini-pools by manufacturers (where appropriate);
- the conditions of storage before analysis;
- the exact description of the test conditions including precautions taken to prevent cross-contamination or destruction of the viral nucleic acids, reagents and reference preparations used;
- the exact description of the apparatus used;
- the detailed formulae for calculation of results, including statistical evaluation.

The inclusion of an appropriate threshold control (for example, plasma spiked with a B19V DNA sample suitably calibrated in International Units, such as *B19 virus DNA for NAT testing BRP*) is considered to be a satisfactory system-suitability check and ensures that the reliability of the analytical procedure is maintained whenever used.

Technical qualification An appropriate installation and operation qualification programme should be implemented for each critical piece of the equipment used.
For confirmation of analytical procedure performance after a change of critical equipment (e.g. thermocyclers), the change should be documented by conducting a parallel test on 8 samples of a plasma pool that is spiked with a concentration of B19V DNA around the threshold concentration. All results should be acceptable and reflect the features of the assay as determined during the validation phase.

Operator qualification An appropriate qualification programme should be implemented for each operator involved in the testing.

M. Assay of Interferons

(Ph. Eur. general texts 5.6)

The following chapter is published for information.

1. INTRODUCTION

Monographs on human interferons generally contain a bioassay based on the inhibitory activity of the interferon on the cytopathic action of a virus on a cell line in culture. In most cases, however, the virus, cell line and the assay details are not specified, in order to allow the appropriate flexibility, where the monograph covers more than one sub-class of interferon.

The present text is intended to provide outline information for the analyst on how to design, optimise and validate such an assay once an appropriate combination of cell line and cytopathic virus has been identified. A detailed procedure for a particular cytopathic antiviral assay is described as an example of a suitable method, together with information on other virus-cell line combinations and guidance on how to adapt and validate the procedure for these other combinations.

2. ANTIVIRAL (CYTOPATHIC EFFECT REDUCTION) ASSAYS

The antiviral assay of human interferons is based on the induction of a cellular response in human cells, which prevents or reduces the cytopathic effect of an infectious virus. The potency of interferon is estimated by comparing its protective effect against a viral cytopathic effect with the same effect of the appropriate reference preparation calibrated in International Units.

3. INTERFERON ASSAY USING HEP2C CELLS AND INFECTIOUS ENCEPHALOMYOCARDITIS VIRUS

The antiviral assay of human interferons described is of the cytopathic effect reduction type. It uses human Hep2c cells infected by encephalomyocarditis virus (EMCV) to measure the potencies of different human interferon test preparations. This assay has been used in three World Health Organization (WHO) international collaborative studies of candidate International Standards for human interferon alpha, human interferon beta and human interferon gamma and has repeatedly been demonstrated to be sensitive, reliable and reproducible for potency estimations of the different types of human interferon.

For the culture of mammalian cells, all procedures are carried out using standard operating procedures for the

maintenance of such cell lines in culture. Volumes of reagents are indicated for cell cultures carried out in 75 cm^2 flasks. Other types of containers (flasks or plates) may be used but volumes must be adapted accordingly.

3.1. MAINTENANCE AND PREPARATION OF HEP2C CELLS

Hep2c cells are maintained and passaged in culture medium A.

Cells are stored as frozen stocks using standard operating procedures. Growing cells may be maintained in culture up to a permitted passage number of 30, after which new cultures are established from frozen stocks.

At the beginning of the assay procedure, harvest the cells from the flasks showing 90 per cent confluent monolayers using the trypsin-treatment procedure described below.

— Remove the culture medium from the flasks.
— To each flask, add 5 mL of trypsin solution heated at 37 °C (a trypsin stock solution contains 4 mg/mL of *trypsin R* and 4 mg/mL of *sodium edetate R*; immediately before use, dilute 50 times with phosphate buffered saline). Swirl the capped flask to wash the cell monolayer. Remove the excess of trypsin solution.
— Incubate the flasks for 5 min to 10 min at 37 °C. Microscopically or visually observe the cells for signs of detachment. When viewed microscopically, the cells appear rounded up or detached and free-floating. Shake the flask vigorously to detach all the cells, add approximately 5 mL of culture medium A. Shake vigorously to yield a suspension of single cells.
— To prepare the cell suspensions for the assay procedure, carefully disperse the cells by pipetting up and down to disrupt cell aggregates, count the cells and resuspend at a concentration of 6×10^5 cells/mL.

3.2. PROPAGATION OF ENCEPHALOMYOCARDITIS VIRUS

Encephalomyocarditis virus is propagated in mouse L-929 cells in order to produce a stock of progeny virus. L-929 cells are maintained by trypsin treatment and passage as described for Hep2c cells (*NOTE: it may be necessary to substitute neonatal calf serum with foetal bovine serum if the cells show poor growth*).

Take several flasks containing confluent cultures of L-929 cells. Pour off the medium from the flasks. Inoculate with 2 mL of the EMCV suspension appropriately diluted in culture medium B so that it contains approximately 2.5×10^8 plaque forming units (PFU) per millilitre. Each flask will contain $4\text{-}6 \times 10^7$ L-929 cells and therefore the multiplicity of infection (m.o.i.) will be approximately 10 PFU/cell. Carefully swirl the virus suspension over the entire cell monolayer and return the flasks to the incubator for approximately 1 h. Maintain the medium at pH 7.4 to 7.8.

After adsorption of the EMCV, add approximately 40 mL of culture medium B to each flask and return the flasks to the incubator at 37 °C for about 30 h. Maintain the medium at pH 7.4 to 7.8 to obtain a maximum virus yield. Remove the culture fluid and store at approximately 4 °C.

Place the flasks at −20 °C to freeze the cell monolayer. Then thaw to room temperature. Add approximately 5 mL of culture medium and shake the flask to disrupt the cell walls. Transfer the contents of each flask to the container of culture fluid. Transfer the culture fluid containing the EMCV to 50 mL plastic centrifuge tubes and centrifuge at approximately 500 *g* for about 10 min to remove cell debris. Dispense the clarified culture fluid into glass screw-capped bottles, in quantities of 20 mL, 10 mL, 5 mL, 1 mL, 0.5 mL or 0.2 mL, as appropriate. Store at −70 °C. Larger volumes can be thawed, dispensed into smaller quantities and re-frozen when required. The EMCV stock will retain its original titre if stored permanently at approximately −70 °C, but repeated freeze-thaw cycles or storage at higher temperatures, e.g. at approximately −20 °C, results in progressive loss of titre.

3.3. ASSAY PROCEDURE

3.3.1. Determination of the dose-response range

Preparation of the solutions

Dilute the appropriate standard for interferon (for example a specific WHO sub-type interferon standard) in culture medium A, in 10-fold dose increments, to give doses covering the range of 1000 - 0.001 IU/mL. Carry out the assay procedure in 96-well microtitre plates. To each well add 100 µL of culture medium A. Add approximately 100 µL of each dilution of the reference preparation to each well except for those intended for virus controls. Using a multichannel pipette set at 100 µL, mix the contents of the wells.

Dispensing of the cell suspension

Pour the cell suspension of Hep2c cells, which has been adjusted to contain approximately 6×10^5 cells/mL of culture medium A, into a plastic Petri-dish. Dispense the cell suspension from the Petri-dish into each well of the microtitre plates, using a multichannel pipette set at 100 µL.

Incubate the plates for about 24 h in an incubator set at 37 °C and 5 per cent CO_2.

Viral infection

At this stage, using an inverted microscope, check that the monolayers of Hep2c cells are confluent, that they show a relatively even distribution of cells, that they have correct morphology and that they are healthy.

Remove most of the culture medium from the wells by inverting the plate and shaking it and blotting on a paper towel (proceed in an identical way when discarding fluids from micro-titre plates as described later). Dilute the EMCV stock with fresh culture medium A to a titre of approximately 3×10^7 PFU/mL (*NOTE: each plate requires approximately 20 mL of diluted virus, plus 5 per cent to 10 per cent of extra volume*). Dispense the diluted suspension from a 9 cm sterile Petri-dish using a multichannel pipette set at 200 µL to all wells including virus controls, but excluding cell controls. Add approximately 200 µL of culture medium A without virus to each of the cell control wells.

Return the plates to the incubator set at 37 °C and 5 per cent CO_2 for approximately 24 h.

Staining

Examine the plates microscopically to check that the EMCV has caused a cytopathic effect (c.p.e.) in the virus controls. The time interval for maximum c.p.e. may vary from one assay to the next because of inherent variation of Hep2c cells to virus challenge over a given period of continuous cultivation.

Remove most of the culture medium from the wells by discarding into an appropriate decontaminating solution (sodium hypochlorite is suitable). Dispense *phosphate buffered saline pH 7.4 R* into each well. Discard the *phosphate buffered saline pH 7.4 R* into a decontaminating solution. Dispense into each well 150 µL of staining solution. Stain the cells for approximately 30 min at room temperature. Discard the staining solution into a decontaminating solution. Dispense approximately 150 µL of fixing solution. Fix for 10 min at

room temperature. Discard the fixing solution into a decontaminating solution and wash the cell monolayers by immersing the assay plates in a plastic box containing running water. Discard the water and superficially dry the plates with paper towels. Dry the assay plates at 20 °C to 37 °C until all moisture has evaporated.

Add 150 µL of *0.1 M sodium hydroxide* to each well. Elute the stain by gentle agitation of the plates or by hitting them against the palm of the hand. Make sure that the stain is evenly distributed in all wells before making spectrophotometric readings.

Read the absorbance at 610 nm to 620 nm, using a microtitre plate reader, taking as a blank a well or a column of wells containing no cells and approximately 150 µL of *0.1 M sodium hydroxide*.

Estimate the concentrations of interferon standard that give the maximum and minimum reduction of cytopathic effect. This is the dose response corresponding to the working range of the assay.

3.3.2. Assay procedure

Carry out the assay as described above, using:

— as test solutions, the substance to be examined, diluted in two-fold increments with culture medium A to give nominal concentrations covering the working range of the assay,

— as reference solutions, the appropriate standard for interferon (for example, a specific WHO sub-type interferon) in culture medium A, diluted in two-fold increments to give nominal concentrations covering the working range of the assay.

3.3.3. Data analysis

Results of the cytopathic effect reduction assay generally fit a sigmoidal dose-response curve, when the interferon concentration (the log of the reciprocal of the interferon dilution) is plotted versus stain absorbance.

Plot the interferon concentration (log reciprocal of dilution) versus the stain absorbance for the interferon reference preparation and for the interferon test solutions. Using the linear portion of the curve, calculate the concentration of interferon in the sample by comparing the responses for test and reference solutions, using the usual statistical methods for a parallel line assay.

4. VALIDATION OF OTHER PROCEDURES

4.1. CHOICE OF CELL LINE AND VIRUS

A number of other combinations of cell line and virus have been used in anti-viral assays for interferons. For example, EMCV has been used in combination with the A549 epithelial lung carcinoma cell line, Semliki Forest virus or Sindbis virus have been used with human fibroblasts, and vesicular stomatitis virus has been used with either human diploid fibroblasts, the human amnion WISH cell line or the Madin-Darby bovine kidney cell line. In each case the choice of the cell line/virus combination is usually based on that which gives the most sensitive response to the interferon preparation to be assayed, and gives parallel responses when comparing the test preparation and interferon standard.

4.2. CHOICE OF RESPONSE

The staining procedure described above measures remaining viable cells. A number of other responses have been used, including methyl violet or crystal violet staining, or the thiazolyl blue (MTT) conversion procedure. In each case, the method is selected on the basis of producing a suitably linear and sensitive relationship between response colour and viable cell count.

4.3. STATISTICAL VALIDATION

As with all parallel line bioassays, the assay must satisfy the usual statistical criteria of linearity of response, parallelism and variance.

4.4. VALIDATION OF ASSAY LAYOUT

As with all microtitre plate assay procedures, attention must be given to validating the assay layout. In particular, bias due to non-random pipetting order or plate edge effects must be investigated and eliminated, by randomising the assay layout, or by avoiding the use of edge wells.

REAGENTS AND CULTURE MEDIA

Culture medium A (10 per cent neonatal calf serum)

RPMI 1640 culture medium, supplemented with antibiotics if necessary (penicillin 10 000 IU/mL; streptomycin 10 ng/mL)	450 mL
L-Glutamine, 200 mM, sterile	5 mL
Neonatal calf serum	50 mL

Culture medium B (2 per cent foetal bovine serum)

RPMI 1640 culture medium, supplemented with antibiotics if necessary (penicillin 10 000 IU/mL; streptomycin 10 ng/mL)	490 mL
L-Glutamine, 200 mM, sterile	5 mL
Foetal bovine serum	10 mL

Staining solution

Naphthalene black	0.5 g
Acetic acid, glacial	90 mL
Sodium acetate, anhydrous	8.2 g
Water	to 1000 mL

Fixing solution

Formaldehyde, 40 per cent	100 mL
Acetic acid, glacial	90 mL
Sodium acetate, anhydrous	8.2 g
Water	to 1000 mL

N1. Numeration of CD34/CD45+ Cells in Haematopoietic Products

(Ph. Eur. method 2.7.23)

This chapter describes immunolabelling and analysis by flow cytometry (*2.7.24*) to determine the number of CD34/CD45+ cells contained in haematopoietic products. The determination is carried out by a single platform method using calibrated fluorospheres, after lysis of the sample red blood cells if necessary.

This method applies to all types of preparations and whole blood. However, the characteristics of this method make it particularly suitable for preparations containing very low percentages of CD34/CD45+ cells.

Graft quality assessment by CD34/CD45+ cell enumeration

A variety of studies have established that the 1-3 per cent of cells in the bone marrow that express the CD34 cell surface antigen are capable of reconstituting long-term, multilineage haematopoiesis after myeloablative therapy.

CD34/CD45+ cells are also found in the peripheral circulation of normal individuals but are extremely rare (0.01-0.1 per cent). However, CD34/CD45+ cells may also be mobilised from marrow to the peripheral circulation in greater numbers by haematopoietic cytokines such as granulocyte colony-stimulating factor and/or chemotherapy.

The technique used for enumeration of CD34/CD45+ cells must meet the following requirements:
— high sensitivity, since haematopoietic stem cells are rare events;
— accuracy, to provide clinically relevant results;
— reproducibility, to provide clinically reliable results;
— speed, to provide real-time analysis.

Selection of parameters
The flow cytometry assay uses commercially available, directly conjugated fluorochrome-labelled monoclonal antibodies, routine staining and whole blood lysing procedures, and a gating strategy using light scatter and immunofluorescence analysis using a pan-CD45/CD34 monoclonal antibody combination.

It is possible to determine CD34/CD45+ cell viability by appropriate nucleic acid staining with a stain that does not cross the intact cell membrane (for example, with 7-aminoactinomycin D).

Selection of monoclonal antibodies
CD34 antibodies Use class III CD34 antibodies that detect all glycosylation variants of the molecule (for example, clone 8G12 or 581). To detect rare events, use an antibody conjugated to the brightest fluorochrome excitable using an argon laser-based flow cytometer, for example phycoerythrin (PE).

CD45 antibodies Pan-CD45 antibodies that detect all isoforms and all glycoforms of this structure are required. A CD45 antibody conjugated to fluorescein isothiocyanate (FITC) fluorochrome is generally used (for example, J33, HLe1, 2D1).

Isotypic or isoclonic controls A negative control is analysed to detect any non-specific signal in the PE fluorescence region. If using an isotypic control (a monoclonal antibody to an irrelevant antigen of the same isotype as the CD34 antibody employed), the PE-conjugated isotype is combined with CD45-FITC (or PerCP). If using an isoclonic control, the unconjugated (in excess) and PE-conjugated CD34 identical monoclonal antibody is combined with conjugated CD45. Alternative combinations may be used.

Absolute count of CD34/CD45+
Calibrated fluorospheres Depending on the technique used, the internal standard either consists of calibrated beads in suspension or is directly introduced into the associated tubes by the manufacturer.

The absolute count of the CD34/CD45+ cells per microlitre is calculated using the following expression:

$$\frac{A}{B} \times C$$

A = number of CD34/CD45+ cells counted;
B = number of fluorosphere singlets counted;
C = known fluorosphere concentration.

Gating strategies
The purpose of sequential gating is to select the population of interest and simultaneously minimise interference from debris and mature cells to which antibodies can bind non-specifically. If using a commercial kit, apply the gating recommended by the manufacturer. If using an in-house assay, it is preferable to apply a currently recommended strategy. A gating strategy that uses light scattering parameters and CD34/CD45 fluorescence will aid in the accurate identification and enumeration of CD34/CD45+ cells.

Number of events analysed
A sufficient number of events are analysed to maintain acceptable accuracy and precision, for example not fewer than 100 CD34+ events and not fewer than 60 000 CD45+ events; the total number of cells counted may be greater if the percentage of CD34 is 0.1 per cent or less.

Specimen collection
Acid citrate dextrose (ACD) formula A is the anticoagulant used in apheresis procedures. This anticoagulant allows both an automated leucocyte count and flow cytometry evaluation to be performed on the same specimen. Edetic acid (EDTA) is the anticoagulant of choice for peripheral blood sampling.

Specimen transport
Transport conditions guarantee the physical and thermal safety of samples.

Specimen integrity and storage
Fresh (less than 24 h old) apheresis products, whole blood samples, umbilical cord blood specimens or bone marrow samples can be processed. Old specimens (more than 24 h old) and specimens that have been frozen and thawed are stained with a viability dye. On receipt, the temperature within the package is verified.

TECHNIQUE

Sample preparation
Ensure that the concentration of leucocytes is suitable prior to staining with monoclonal antibodies. If necessary, dilute the sample with medium that is compatible with the product to be tested and the lysing system. Record the dilution factor. It is recommended to perform the test with a negative control.

Flow cytometry analysis
Autostandardisation

For analysis of cells labelled with a commercially available kit, manufacturers have developed some quality tools for setting the flow cytometer. These settings are then automatically transferred on protocol analysis of samples. Specific fluorospheres are used to set the photomultiplier tube (PMT) on target values, compensation is set and the system is checked using a control preparation.

System settings
— *Discriminator/threshold*: the forward angle light scatter threshold is set to exclude debris (low forward scatter) but not small lymphocytes from the light-scatter plot.
— *PMT high voltage settings*: these must be consistent with cell-surface marker analysis and established within each laboratory so that negative and positive cell populations of moderate antigen density can be distinguished; PMT voltages are reviewed and adjusted periodically according to standardised laboratory procedures.
— *Compensation*: this must be acceptable for the colour spectra overlap (for example, FITC/PE) encountered in cell-surface marker analysis; colour compensation is analysed and adjusted according to standardised laboratory procedures.
— *Flow rate*: this must be consistent with routine cell-surface marker analysis.
— *Gating regions*: the gating regions established for the CD34/CD45 samples are maintained unaltered for the analysis of the negative region.

Calculation of absolute number of CD34/CD45+ cells
The absolute number of CD34/CD45+ cells is calculated using the following expression:

$$n \times D \times V$$

n = total number of CD34/CD45+ cells per microlitre;
D = dilution factor;
V = volume of the product to be tested, in microlitres.

Results are reported as both the percentage of CD34/CD45+ cells and the absolute number per microlitre. They may also be reported as the absolute number per kilogram of recipient body mass, where this is possible.

N2. Colony-forming Cell Assay for Human Haematopoietic Progenitor Cells

(Ph. Eur. method 2.7.28)

The haematopoietic system represents a continuum of cells whose phenotype and properties change as they progress from stem cells to differentiated cells.

Haematopoietic progenitor cells (HPCs) are capable of forming colonies or 'cell clusters' in cultures grown in semi-solid media and are said to be 'clonogenic'.

The determination of the number of colony-forming cells (CFCs) in a cellular product is an indicator of the functional capacity of the progenitor cells and is a predictor of haematopoietic reconstitution. The measured number of CFCs correlates with the minimum number of progenitors present in the sample.

CELL-SURFACE MARKERS

The capacity of colony-forming cells to give rise to haematopoietic colonies *in vitro* and/or to reconstitute the haematopoietic system has been correlated with the expression of specific cell-surface antigens. The expression of the membrane antigen CD34 is an accepted marker for most of the haematopoietic progenitors and stem cells.

COLONY ASSAY SPECIFICITY

Colony-forming cells are identified with a nomenclature based on the lineages of mature cells present in the colony (for example, CFU-Mix, CFU-GEMM, CFU-GM, CFU-G, CFU-M, BFU-E, CFU-E, CFU-Meg) and are a population of progenitors able to give rise to colonies containing one or more lineages of haematopoietic cells. No or low capacity for self-renewal has been ascribed to this population of human HPCs compared with the most immature stem cells.

The amount and type of growth factors supplied during the culture modulate the type and size of colonies that will be formed.

Greater specificity on the general class of HPCs and on their relative proliferative potential is provided by the time required to differentiate *in vitro* into mature cells. The time required by post-natal colony-forming cells to give rise to a colony formed of mature cells *in vitro* is 10-14 days.

QUALITY ASSURANCE FOR A CFC ASSAY

It is paramount for the overall quality of the colony-forming cell assay to apply a strictly standardised approach. It is therefore recommended to carry out intra- and inter-laboratory validations. The source of the materials, including reagents, growth factors and disposables, is identified.

The main factors affecting variability in the CFC assay are the number of cells plated and the identification of colonies. Up to 15 per cent intra-laboratory variability may be observed for the same test. If it is necessary to evaluate the number of colony-forming cells in a purified cell population, it is possible to use a limiting dilution approach where the number of wells positive for cell proliferation is measured with an automated system.

The other main source of variability stems from the use of undefined materials (for example, foetal bovine serum or bovine serum albumin) in the CFC assay. These products derive from pools of source materials and provide a non-specific stimulation of cellular proliferation. However, it is not uncommon to have batches with particular characteristics that selectively stimulate the proliferation of specific haematopoietic lineages.

Finally, a low level of endotoxins (less than 0.01 IU/mL or less than 0.01 IU/mg) in all the materials used for the clonogenic assay is advisable, as higher levels result first in a progressive skewing of the haematopoietic lineages expression in the cultures, and afterwards in a more general inhibition of cell proliferation and clonogenesis.

CFC CLONOGENIC ASSAY

The CFC assay is based on the capacity of progenitor cells to form a colony when plated in a semi-solid medium or in a gel in the presence of specific growth factors. Different types of semi-solid media may be used (for example, methylcellulose, collagen, agar and plasma-clot) depending on the desired readout. Commercially available media usually give more reproducible results.

MATERIALS

A validation is performed at least for the following critical materials.

Growth factors

Both multilineage (such as Kit-ligand or stem cell factor (SCF), interleukin-3, granulocyte-macrophage colony-stimulating factor (GM-CSF)) and lineage-specific (erythropoietin, granulocyte colony-stimulating factor (G-CSF)) growth factors are required to obtain the highest number of colonies from a cell suspension containing a mixed population of HPCs.

Other media components

Media may be supplemented by serum (notably by foetal bovine serum) and/or albumin.

CELL CULTURE

Cells

The sample placed in culture must be representative of the cellular product injected. Cell suspensions are required for this assay. In the case of bone marrow aspirates, such suspensions can be obtained by forcing the bone marrow through a sieve or through progressively smaller calibre needles. Repeated passages through a 21-gauge needle are usually sufficient to disperse cell clusters into a cell suspension.

PLATING AND SCORING

The cells diluted in the culture medium are mixed in the semi-solid medium. It is common to plate 1 mL of the mixture in an untreated sterile Petri dish (Ø 35 mm).

Because of the viscosity of the medium, the solution cannot be plated with air displacement pipettes and the use of syringes equipped with large bore (≤ 18-gauge) needles is required.

The number of cells to be plated depends on the HPC concentration in the sample to be tested. So that no colony is derived from 2 different HPCs, the number of cells plated must allow between 40 and 80 colonies per plate (Ø 35 mm) to be counted. The 'target' number of colonies per plate may be obtained either from the percentage of CD34+ (or concentration of CD34+ cells/mL) determined by flow

cytometry (*2.7.24*) or from different dilutions of the cell suspension (usually 2 concentrations are tested).

The plates are incubated in aerobic conditions with a carbon dioxide concentration of 5 per cent, at 37 °C in a humid (saturated) atmosphere for 10-14 days, and the number of colonies is then scored under an inverted microscope. Care must be taken when manipulating the dishes containing the colonies as the methylcellulose-based medium is viscous but not jellified. An inclined plate will result in mixed and 'comet'-shaped colonies making the scoring likely to be incorrect.

IDENTIFICATION OF THE COLONIES

The size and structure of the colonies depend on the type of mature cells that are their constituents. 50 cells per colony is usually considered a minimum. The presence of haemoglobinised cells identifies progenitors of the erythroid lineage. As the amount of mature cells for each lineage largely depends on the growth factors added to the cultures, performing differentiated counts is not recommended unless otherwise prescribed.

EXPRESSION OF THE RESULTS

The results of CFC culture are usually expressed as the arithmetic mean of the number of colonies counted in at least 3 plates in the test. The mean number of colonies is then related to 10^4 or 10^5 viable nucleated cells placed in culture.

N3. Nucleated Cell Count and Viability

(Ph. Eur. method 2.7.29)

The determination of the quality of cell suspensions requires accurate measurements of both cell concentration and percentage of viable cells. These data are essential to the decision-making process for preparing cellular products and for maintaining optimum culture conditions. The cell count may be expressed as the number of cells per volume of cell suspension and the cell viability as the number of viable cells per volume of cell suspension. The cell-count procedure may be performed manually (haemocytometer) or with an automated apparatus (for example, particle counter, flow cytometer). Other methods than that described below may be used.

CELL NUMBER

MANUAL COUNTING

Description of the apparatus and test principle The following materials are required:

- a haemocytometer: a specialised microscope counting chamber available in different designs. It consists of a thick slide and a coverslip mounted to delimit a chamber with a specific volume for each design. The thick slide of the various haemocytometers consists of counting chambers separated by deep grooves to avoid cross-filling. The counting chamber is etched in the glass and contains a grid which is specific for each model;
- a light microscope - low power 10× to 40× magnification;
- pipettes of a suitable volume range.

The haemocytometer is used to quantify the number of cells in a given solution by calculation of the cell concentration per millilitre (C) using the following expression:

$$a \times 10^n \times d$$

a = number of cells counted;
d = dilution factor (where applicable);
n = factor varying with the volume of the haemocytometer chamber.

It is possible to distinguish between mixed cell populations provided they differ in size or pigmentation (for example, leukocytes and erythrocytes).

Preparation of the counting chamber and analysis Mount the coverslip (slightly moistened on the edges) on the slide. Move the coverslip back and forth over the slide, pressing slightly on the sides. Prepare a suitable dilution of the cell suspension in isotonic buffer or in haemolysis buffer.

Add an appropriate volume of the dilution to the counting chamber. The liquid is added to the border of the coverslip and is drained inside the chamber by capillarity. Carefully place the haemocytometer under the microscope and focus. Count the cells in a zone of the grid. Calculate the cell concentration in the diluted and original samples.

To increase the accuracy of the measurement, it is important to respect the following basic precautions:

- use only suitably thickened coverslips;
- wherever possible, count more than 100 cells (if necessary, count more areas);
- where cell clustering is detected (i.e. the cell suspension is not monocellular), resuspend the cells before sampling and count again;
- avoid underfilling or overflowing the chamber, otherwise the volume will no longer be accurate.

AUTOMATED COUNTING METHODS

Particle counters based on conductivity variation Electronic particle counting devices measure the size and number of particles in a solution.

Particle counters are calibrated before use with a solution of particles of known concentration and size. To allow the counting of larger particles, tubes fitted with differently calibrated orifices are available. These apparatuses do not allow the discrimination between dead and live cells. As cell debris may also generate pulses that may cause errors, counters are also fitted with a threshold control allowing only larger particles to be counted.

The apparatus must be qualified for the counting of cellular products (in terms of linearity, accuracy, etc.).

Particle counters based on flow cytometry (*2.7.24*). The flow cytometer is calibrated with reference particles of known concentration and size to give an absolute cell number per volume. However, a calibrating solution is no longer necessary in instruments using 2 electrodes inserted in the sampling chamber where the fixed size of the sampling chamber and distance between the 2 electrodes allow the measurement of the content of a fixed volume. This type of instrument rarely needs to be calibrated after the initial setting.

VIABILITY

This section applies to cell staining by viability dyes and manual or automated analysis, under a light microscope or by flow cytometry, of a cell suspension in order to determine the percentage of viable cells.

Depending on the type of cells and the method used, the results may differ.

MANUAL DYE-EXCLUSION METHOD

Test principle This test is based on the exclusion of the dye from viable cells whereas dead or damaged cells absorb the dye and are coloured. It provides information on the

cytoplasmic membrane integrity but its results do not necessarily reflect cell functionality. Recently trypsinised or thawed viable cells may have leaky membranes, causing them to absorb the dye.

Dye Trypan blue is the stain most commonly used to distinguish between viable and non-viable cells, but other suitable dyes such as erythrosin B or nigrosin may also be used. It is an acid dye (M_r 961), an anion with 4 sulfonate groups that can easily bind to proteins; therefore the protein concentration of the preparation to be tested must be as low as possible.

Test conditions Dye fixation is strongly influenced by pH, within a range of 6.6 to 7.6. Fixation is optimal at pH 7.5. The other conditions, such as the dye concentration and the staining time are validated.

Storage conditions of the dye Generally a 0.4 or 0.5 per cent trypan blue solution in sterile phosphate-buffered saline is used. Store protected from light and air.

Test preparation and analysis Stain the cell suspension at the required dilution (usually in phosphate-buffered saline) with, for example, a trypan blue solution having a final concentration of 0.1 to 0.2 per cent. Mix gently. Incubate for not more than 2-4 min at room temperature. Mix gently and place a suitable volume in a counting chamber. Count without delay.

Determine the percentage of viable cells from the ratio of the number of unstained cells to the total number of cells under a light microscope, considering all stained cells as dead cells. Viability (V) is calculated as a percentage using the following expression:

$$\frac{n}{N} \times 100$$

n = number of unstained (viable) cells;
N = total number of cells (stained and unstained).

It is essential that the incubation time be not more than 4 min as the number of stained cells may increase significantly afterwards. For a new determination, it may therefore be necessary to prepare a new test.

AUTOMATED METHODS

Flow cytometry

Test principle The test is based on the ability of certain dyes to cross damaged membranes and bind to DNA by intercalating between bases so that dead cells may fluoresce and be detected by flow cytometry (*2.7.24*). Non-viable cells are evaluated and discriminated by focusing on positive staining whereas viable cells remain unstained. This analysis is generally performed with 7-aminoactinomycin D (7-AAD) or propidium iodide (PI) but other suitable dyes may also be used.

Dye 7-AAD and PI are given as examples of membrane-impermeants that may be used as viability dyes.

7-AAD is an analogue of actinomycin D that contains a substituted amino group at position 7 of the chromophore. It intercalates between cytosine and guanine DNA bases. The spectral properties of 7-AAD make this molecule particularly suitable for flow-cytometry analysis.
The maximum absorption of the 7-AAD/DNA complex is situated in the green spectral region and is thus suitable for an argon laser-equipped cytometer (excitation wavelength of 488 nm). The deep red fluorescence emission of the 7-AAD viability dye (635 nm to 675 nm) eases the use of the probe in combination with fluorescein isothiocyanate (FITC)-and phycoerythrin (PE)-conjugated antibodies, because in contrast to PI, the 7-AAD/DNA complex shows minimal overlap with FITC and PE.

PI binds to double-stranded DNA by intercalating between bases with little or no sequence preference and with a stoichiometry of 1 dye molecule per 4-5 DNA base pairs. Once the dye is bound to nucleic acids, its fluorescence is enhanced 20- to 30-fold, the fluorescence excitation maximum is shifted around 30-40 nm towards the red and the fluorescence emission maximum (615 nm) is shifted around 15 nm towards the blue. Although its absorptivity is quite low, PI exhibits a sufficiently large Stokes shift to allow simultaneous detection of nucleic acids and fluorescein-labelled antibodies, provided that the suitable optical filters are used.

Storage conditions of nucleic acid dye solution 5 ± 3 °C.

Test preparation and analysis In the case of haematopoietic cells, the dye may be added after CD45 labelling to obtain a better separation of cells from debris and platelets with a side scatter (SS)/CD45+ gating region. The incubation conditions of the cell suspension with the dye are validated previously.

Incubation is performed at room temperature protected from light. Where necessary, lysis of red blood cells is performed using, for example, ammonium chloride. If not, add buffer alone.

Percentages of viable cells are directly given by the flow cytometer and deduced from the analysis of positive cells (dead cells) in the SS/7-AAD or SS/PI cytogram (dot plots).

Positive controls may consist of stabilised cells (dead cells) mixed with fresh viable cells at a target value.

Digital imaging of stained cells

Digital imaging allows the automation of dye-exclusion methods. The cell suspension and viability-dye solution are directly mixed by a machine. The system, which allows sample aspiration, reagent handling, and subsequent instrument cleaning is fully automated. Once the cellular suspension has been aspirated and mixed with the dye solution, it is pumped to the flow cell for imaging.
The stained cell suspension is aspirated through a chamber where stroboscopic light allows a camera to photograph the flowing cells. The images are digitalised and the number of dead or live cells counted by the software.

O. Host-cell Protein Assays

(Ph. Eur. method 2.6.34)

This general chapter provides guidance for the development and validation of host-cell protein (HCP) assays used to test products obtained by recombinant DNA technology. It does not exclude the use of alternative approaches that are acceptable to the competent authority.

INTRODUCTION

Host-cell proteins (HCPs) are process-related impurities derived from the host organism used for the production of a medicinal product by recombinant DNA technology.
In order to mitigate their potential adverse effects (e.g. immunogenicity), HCP content is expected to be reduced to the lowest possible level.

HCP clearance during the purification process must be assessed and the HCP content determined using an HCP

assay that has been evaluated and validated for a given product.

The HCP acceptance limit, typically expressed in nanograms of HCP per milligram of active substance (ppm), must be justified with regard to the HCP clearance capacity of the purification process and with regard to the potential impact of residual HCP on patients, taking into account the worst-case quantity of HCP that could be administered with the product.

HCPs are generally measured using an immuno-based assay containing, as reagents, the HCP antigen preparation (hereinafter 'the HCP antigens') or HCP reference standard and the corresponding polyclonal antibodies (antisera). Antisera must cover a broad spectrum of HCPs representative of the product concerned.

Sandwich-type enzyme-linked immunosorbent assays (ELISA) are the most commonly employed assays to assess quantitatively the level of HCPs. It should be noted that HCP content measured by ELISA does not represent absolute HCP mass content. The sensitivity is the result of the observed cumulative responses of many individual HCPs in comparison to the response of an HCP reference standard. The use of orthogonal analytical methods (e.g. electrophoresis, HPLC, Western blot, mass spectrometry) to characterise the various HCPs in the product is recommended to support the development and selection of the assay.

ASSAY SELECTION

Several types of assay are available, with selection taking into account several factors, including the stage of development of the product, the nature of the host cell and the protein immunogenicity, the expression mode, the manufacturing process, and prior knowledge. When selecting and developing the assay, its life cycle (e.g. reagent supply, consistency, assay validation, process change) must also be considered.

TYPES OF ASSAY

Process-specific assays

Process-specific HCP assays (also called product-specific HCP assays) are developed and validated taking into account the specificity of the production process, and using the same host organism expressing the recombinant product.

The HCP antigens are derived from a mock run of the active substance manufacturing process (or a process representative of it) up to a step capable of generating a broad spectrum of HCPs in sufficient quantities.

The antisera raised must cover a broad range of HCPs, in order to detect as many different HCPs as possible and also to accommodate process variations.

Platform assays

Platform assays are developed by individual manufacturers and customised for the processes and host organism used by the manufacturer for production. The same sets of reference standards and reagents may be used to monitor HCPs in several products manufactured in the same host organism, provided that upstream processes (and downstream, if relevant) are sufficiently similar for these products. The suitability of the antiserum should be evaluated as described above for process-specific assays.

Generic assays

Commercially available HCP test kits are commonly referred to as generic HCP assays. They are intended to work broadly across similar expression hosts. Detailed information on the preparation of the reagents may not be disclosed by the vendor. For instance, the HCP antigens may be derived from a combination of strains of an expression host species, and the process(es) used may not mimic the process applied for the product of interest. The suitability of the antiserum should be evaluated as described above for process-specific assays.

CRITERIA FOR ASSAY SELECTION

In view of the potential safety issues associated with residual HCPs in the active substance, a risk assessment is performed to support the choice between a generic, a platform or a process-specific strategy, taking into account the stage of development of the product.

For early development a generic assay or a platform assay may be used. For later development phases, process-specific assays must be considered, as they are generally regarded as superior, especially when compared to generic assays. This is because process-specific assays are more likely to show immunoreactivity against representative HCPs.

Platform or generic assays may be used, provided that the assay is appropriately characterised and validated against process-specific HCPs.

PRODUCTION AND TESTING OF THE HCP ANTIGEN PREPARATION

The HCP reagents (HCP antigens and anti-HCP antibodies) are produced in such a way as to facilitate replication of the production when a replenishment for the HCP assay is needed.

The HCP antigens are used to generate the polyclonal antibody reagent for the HCP immunoassay by immunising one or more suitable animal species. In addition, they serve as the HCP reference standard in the HCP immunoassay.

As far as possible, the HCP antigens must cover the relevant HCP population expected to be derived from the manufacturing process of the protein of interest.

The HCP population must also be broad enough to cover worst-case purification scenarios and to provide robustness against potential manufacturing process changes during the life cycle of the product.

PROCESS-SPECIFIC ASSAYS

Null cell line

Development of a process-specific assay involves the selection of a null cell line that does not contain the expression gene for the product of interest and is derived from the same cell line that has been used to establish the production cell line. This null cell line may be non-transfected or mock-transfected. A mock-transfected cell line is created by transfecting the parental cell line with a blank plasmid, i.e. the plasmid used to create the production cell line, but missing the gene coding for the protein of interest.

Mock production process

Upstream

The antigens produced for process-specific assays are obtained by a mock production process that mimics the intended manufacturing process, using the null cell line and, as far as possible, the same operating conditions.

As for any mock production, the process used represents an approximation of the intended manufacturing process and leads to differences (e.g. different scale, operating parameters, product interaction). However, the impact of those differences needs to be considered carefully because they may affect the composition of the HCP population.

For example, a mock fermentation of an inclusion body manufacturing process may not deliver the desired inclusion bodies if the product is not present. Therefore, depending on

the null cell line used (e.g. mock-transfected or not), the antigens may need to be isolated differently compared to the intended manufacturing process.

In some situations, operating parameters for the mock production may be adjusted to cover worst-case scenarios (e.g. to deliver antigens covering a broad spectrum of different HCP species). For example, the antigen-containing cell culture supernatant may be harvested beyond the minimum level of cell viability in order to include more cytosolic proteins, which are released by additional cell lysis.

Downstream

The HCP antigens derived from the upstream process are usually only minimally processed (filtration, concentration), in order to obtain a representative spectrum of HCPs. Further purification is generally not recommended as there will be a risk of losing HCP species.

However, in cases where the antigens are not representative (e.g. resulting in low coverage), mixing of mock materials from different processing steps can be considered. Enrichment may also be achieved by pooling materials from mock fermentation or purification runs using different operating conditions, or from selective purification steps (e.g. to reduce large amounts of the few immunodominant HCPs).

Cross-contamination with the protein of interest

The HCP antigens must be produced in a manner that avoids contamination with even minute traces of the product in order to avoid cross-reactivity with the polyclonal antibodies.

To achieve this goal, dedicated or single-use equipment is used as much as possible. Where multi-purpose equipment is used, it must be cleaned appropriately. In addition, the risk of contamination when filling or handling the antigens in the laboratory environment must also be considered.

Characterisation and testing

Before using the HCP antigens for immunisation, the protein content is assessed (total protein assay) and the absence of the protein of interest verified.

Comparison of the HCP population with the mock and the intended production process is performed, typically by SDS-PAGE and/or two-dimensional (2D) electrophoresis with a high sensitivity stain. The aim of this comparison is to show that the HCP antigens resulting from the mock production process contain most of the representative HCP species of the intended manufacturing process. Where necessary, complementary information may be gathered by orthogonal methods, e.g. mass spectrometry.

PLATFORM ASSAYS

Null cell line

Development of a platform assay involves a null cell line that does not contain the expression gene for the product of interest, and uses the same host species. This null cell line may be non-transfected or mock-transfected, and may be used for the production of HCP antigens for products from a given company's manufacturing platform.

Mock production process

Upstream

The HCP antigens produced for platform assays are obtained by a mock production process that mimics the platform upstream process that is used for several products, and typically uses the same media components. As for any mock production, the process used represents an approximation of the intended manufacturing process, which may impact the composition of the HCP population (see process-specific assays).

Downstream

As for other assays, the HCP antigens derived from the upstream process are, in general, only minimally processed (e.g. no or limited number of purification steps) to obtain a broad spectrum of HCPs, although mixing and pooling strategies may also be used to widen the spectrum of HCP species.

Characterisation and testing

As for process-specific assays, both the protein content and the absence of the protein of interest are tested. Comparison of the HCP population with the mock and the intended production process is performed.

GENERIC ASSAYS

Generic assays are commercially available and are developed by the vendor.

Detailed information on the preparation of the reagents may not be disclosed by the vendor. For instance, the null cell line may be derived from a combination of strains of an expression host species, and the process(es) used may not mimic the process applied for the product of interest.

Nevertheless, the generic assay must be selected with consideration given to the intended manufacturing process (e.g. appropriate host cell line), and be appropriately validated for the product of interest and phase of development. As a consequence, if generic assays are used in later stages of development or during commercial manufacturing, it is recommended to validate the assay and control lot-to-lot reagent consistency using either appropriate upstream fractions from the production process or a mock preparation generated using a null cell line.

PRODUCTION AND CHARACTERISATION OF THE ANTI-HCP ANTIBODY REAGENT

PROCESS-SPECIFIC AND PLATFORM ASSAYS

Immunisation

One of the challenges of the immunisation step is to generate polyclonal antibodies that are highly specific and sensitive for each of the antigenic proteins in the complex mixture of HCPs used as an immunogen. An animal's immune response must be stimulated against both the stronger and the weaker antigens.

An animal host that yields a sufficient quantity and diversity of HCP-specific immunoglobulin G (IgG) is selected.

Where both the polyclonal capture and the polyclonal detection antibodies are from the same source, it can be assumed that they recognise different epitopes on the same HCP in the assay. Alternatively, polyclonal anti-HCP antibodies from different animal species may be used. Using several animals for a given species may reduce the impact of individual variations in immune competence and provide additional response diversity, resulting in maximised antibody coverage against the HCP antigens.

An immune response to a limited number of HCP antigens may be obtained rapidly, particularly when adjuvants are used to boost the immune response. However, in complex mixtures, differential enhancement of the immune response towards weaker antigens or those at lower concentrations may be necessary.

It usually takes several immunisations to reach a maximum immunological response and, depending on the frequency of immunisation, the process can take 3-6 months to complete.

The immune response against the HCPs for a given immunisation scheme has to be monitored by determining the antibody titre using, for example, an ELISA, and by

comparing the results of 1D or 2D electrophoresis after protein staining and a Western blot, where the polyclonal anti-HCP antibodies are used as primary antibody.
In practice, some minor proteins that elicit a strong immune response may not be visible in the protein-stained gel, and some poorly antigenic proteins that are detectable by protein staining may not elicit a detectable immune response.
To achieve sample-dilution linearity in complex multi-analyte immunoassays, it is essential that the immune reagent simultaneously and specifically recognises as many individual analytes as possible in an assay sample and that it is present in stoichiometric excess. For this purpose, a series of sample dilutions from different process steps may be tested by ELISA using purified anti-HCP antibodies from bleedings that have shown suitable coverage by Western blot.

Finally, based on the results of the tests described above, antisera from different animals are pooled, retested and purified.

Purification and preparation
The HCP antibodies must be purified before an assay can be developed.

Typically, this is achieved by protein A- or protein G-chromatography and/or HCP antigen affinity chromatography. In the case of HCP antigen affinity chromatography, the antigens used for immunisation are immobilised on column chromatography media and the specific antibodies are captured by applying the antisera onto the column.

Additional purification to remove potential aggregates might be required by gel permeation chromatography.

For the ELISA, a part of the purified anti-HCP antibodies is conjugated to a detection label (e.g. biotin or horseradish peroxidase).

The purified anti-HCP antibodies and the sera must be stored at a temperature that ensures their stability.

Characterisation and testing
The suitability of the derived HCP assay reagent is assessed by demonstrating the coverage of the HCPs representative of the manufacturing process by the anti-HCP antibodies.

For this purpose, 2D electrophoresis of the HCP antigens is performed. The protein pattern of the immunostain is compared with the protein pattern of the total stain.
The anti-HCP antibodies must recognise a broad range of HCPs over the full range of charge and molecular size. Other methods using native conditions may be considered.

GENERIC ASSAYS
Immunisation, purification and preparation of the anti-HCP antibody reagent are carried out by the vendor and details may not be available.

Characterisation and testing of anti-HCP antibodies are performed as for other assay types. Typically, there is limited control over lot-to-lot reagent consistency. Appropriate comparative lot testing is therefore required.

VALIDATION OF THE HCP ASSAY
The HCP ELISA is developed to detect and quantify a heterogeneous mixture of antigens at varying concentrations, and with a reagent containing antibodies that are not represented at a one-to-one ratio. The section below is intended to target the specifics in development and validation of this type of ELISA.

HCP assays such as ELISA are validated with regard to accuracy, specificity, precision, quantitation and detection limits, linearity, range and robustness.

During the life cycle of the product, a full or partial revalidation of the assay may be required, for example when implementing a manufacturing process change that may impact the suitability of the HCP reagent.

Accuracy
Accuracy is demonstrated by spike/recovery analysis of the HCP reference standard in a relevant background matrix (e.g. the active substance or a sample from a relevant purification step).

Specificity
Specificity is demonstrated by the absence of interference from the matrix background (including the active substance). For instance, data from the accuracy study can be used to assess specificity.

Precision
As for any other quantitative assay, repeatability, intermediate precision and reproducibility are appropriately demonstrated.

Quantitation and detection limits
Sensitivity is usually in the ppm range and is normally described through the quantitation limit (QL). QL is typically determined by HCP spike recovery studies in the active substance or an appropriate sample matrix, and is calculated from the minimal spike providing a response with predefined accuracy and precision from replicate analyses.

Detection limit (DL) is often not determined (optional validation parameter).

Linearity
The linearity of the HCP assay is demonstrated using dilution series of the HCP standard and spike/recovery experiments (accuracy study).

Additionally, due to the nature of HCP assays, the multiple HCP analytes and polyclonal anti-HCP antibodies, sample-dilution non-linearity may be observed, i.e. back-calculated results increase with increasing dilutions of samples, which in most cases is related to the excess of one or more individual HCPs in the sample when compared to the available antibodies in the HCP immunoassay. As a consequence, dilution linearity must be properly assessed for the relevant process steps by comparison of target versus measured HCP concentrations at varying sample dilutions. Dilution linearity is demonstrated if the acceptance criteria for assay variation are met for different sample dilutions. Studies demonstrating dilution linearity can be carried out either during method development or at the latest during method validation.

If a sample shows dilution non-linearity, multiple sample dilutions are prepared beyond the range where non-linear behaviour is observed.

The final HCP value is typically reported as the average HCP concentration obtained for a minimum of 2 dilutions within the linear dilution range. If justified, 1 dilution may be sufficient.

Range
The range of the assay is typically defined by the HCP concentrations for which a suitable level of precision, accuracy and linearity has been demonstrated.

Robustness
The evaluation of robustness is considered during the development phase.

CHANGE OF HCP ASSAY AND/OR REAGENT
The quantities of antigens and antibodies must be large enough to supply the HCP assay for several years. Therefore, the supply, quality and consistency of reagents must be appropriately managed throughout the life cycle of the assay.

Table 2.6.34.-1

	Depleted reagents		Process change
	HCP reference standard	Anti-HCP antibody	
Reagent characterisation	The protein concentration of the new reference standard is determined preferably using the same method as for the current reference standard to ensure that the protein concentrations are comparable. Using suitable methods (e.g. 1D-/2D-PAGE, 2D-DIGE), the similarity in protein composition between the new and current HCP reference standards is assessed.	Total protein concentration of the new antibody is determined. The final assay concentration must be titrated for the new lot in order to achieve a similar standard curve as for the current lot. For detection antibodies, the detection label: protein stoichiometry is controlled and ensured to be similar to the current antibody lot. Immunoreactivity of the new antibody is compared qualitatively (by visual comparison) or semi-quantitatively (coverage determination) against the current lot by suitable methods (e.g. 1D or 2D Western blot). Due to the variability of the method, it is particularly advisable to perform this characterisation side-by-side with the current antibody lot.	The effects of process changes that have the potential to impact the HCP composition are analysed by suitable methods (e.g. 1D-/2D-PAGE, Western blot, HCP assay). If the process change does not lead to a relevant change in HCP composition, the current HCP reagents are also suitable for the new process. If the process change does lead to a relevant change in HCP composition, but the suitability of the current HCP reagents was demonstrated, the current HCP reagents are also suitable for the new process. If the process change does lead to a relevant change in HCP composition, but the current HCP reagents were shown to be unsuitable for the new process, a new assay must to be developed including a mock fermentation according to the new process and a new immunisation.
Testing of reagents in HCP assays	The new HCP reference standard is quantitatively tested against the current reference standard for spike recovery at different concentrations covering the validated assay range. Standard curves obtained with the new versus the current reference standard are assessed for similarity.	Standard curves obtained when using new versus current antibody lots are compared. A bridging study is performed with testing of relevant process samples (e.g. purification steps from harvest to the final active substance). In a side-by-side experiment, new antibodies must detect HCP levels at different process steps equally or with an improved quantitation limit.	A mock run harvest from the new process is tested for spike recovery using the current HCP assay. Relevant process samples (e.g. purification steps from harvest to the final active substance) from the new and the previous process are tested side-by-side.
Assessment of validation status	If reagent characterisation and ELISA testing demonstrate suitability of the new HCP reference standard, the current reference standard can be replaced. No revalidation of the test method is required. If the new HCP reference standard differs significantly in protein composition and/or assay performance from the current reference standard, revalidation is required.	If reagent characterisation and ELISA testing demonstrate that the new antibody is suitable, the current antibody can be replaced. No revalidation of the test method is required. If the new antibody differs significantly in Western blot immunoreactivity or immunoassay sensitivity and/or assay performance compared to the current antibody, revalidation is required.	If, for the new process, the antibody shows similar or higher immunoreactivity compared to the previous process, and the HCP assay shows adequate recovery from the mock harvest of the new process and also similar or higher sensitivity for samples from the relevant process steps, then the current assay and reagents are considered suitable for the new process. No revalidation of the test method is required. If reagents appear suitable to detect HCP from the new process, but the ELISA indicates significant differences in spike recovery of the mock sample or of HCP levels at relevant process steps, then revalidation is required. The process change might also impact dilution linearity of test samples from certain process steps; if these steps are essential for the HCP control strategy, revalidation or even generation of new antibody reagents might be required. In case of a major change in HCP composition with the new process that leads to either a mismatch in protein composition compared to the current assay standard, reduced immunoreactivity of the antibody, or significantly decreased immunoassay sensitivity, then new assay reagents are prepared and the HCP assay is validated with the new reagents.

PAGE: polyacrylamide gel electrophoresis
DIGE: differential gel electrophoresis

For generic HCP assays, in order to ensure the consistency and quality of the reagents, recharacterisation or revalidation of the assay may be required for each new batch of reagent, as their quality may change from one batch to another.

For process-specific and for platform assays, there are generally 2 situations where new HCP assay reagents may be required:

— the HCP reference standard and/or antibody are depleted; antibody may then be purified from a frozen serum stock or a new immunisation is required;

— a manufacturing process change can impact the HCP composition for the purification intermediates or the final product; the assay reagent may not be properly suited to detect and quantify the modified HCPs; a manufacturing process change can therefore render the reagents unsuitable for assay use.

Newly prepared reagents must be thoroughly characterised (e.g. by 2D-SDS-PAGE/Western blot for coverage, 2D-SDS-PAGE/differential gel electrophoresis (DIGE)/identification by MS). Afterwards, the validation status of the assay using the new reagents must be assessed. It is recommended to perform these experiments side-by-side with the currently used reagents.

Table 2.6.34.-1 outlines a recommendation for reagent characterisation and assessment of immunoassay validation, as a consequence of a depletion of assay reagents or a process change.

O2. Quantification and Characterisation of Residual Host-cell DNA

(Ph. Eur. method 2.6.35)

This general chapter describes analytical methods that may be used to measure the content and to characterise the size of residual host-cell DNA in biological products produced in cell substrates. It does not exclude the use of alternative approaches that are acceptable to the competent authority.

INTRODUCTION

Several sensitive analytical methods exist for the quantification of residual host-cell DNA, including real-time quantitative PCR (qPCR) (Method A) and an immunoenzymatic method (Method B).

qPCR may also be used to assess the residual host-cell DNA size distribution, as a characterisation test depending on the nature of the cell substrate (e.g. continuous cell lines) and on the amount of residual host-cell DNA.

A suitable method is selected depending on the nature of the biological product to be tested and taking into account the characteristics and limitations of each method as summarised in Table 2.6.35.-1.

Table 2.6.35.-1 - *Comparison of the characteristics of qPCR and immunoenzymatic methods*

Characteristics	qPCR (Method A)	Immunoenzymatic method (Method B)
Can be used to assess DNA size distribution	Yes	No
Limit of quantification *(may vary depending on the matrix, method and interfering substances)*	0.01-10 pg/mL	2-10 pg/mL
Specificity (total DNA versus specific DNA)	Specific DNA	Total DNA
Interfering substances	Proteins	Detergents/proteins/solvents/RNA
Limitations	Fragments smaller than the PCR product can not be detected and quantified.	Not applicable for DNA-based products. The DNA content is underestimated for fragments below 1000 base pairs (bp). Detectability depends on DNA size. Undetectable short DNA fragments (below 80 nucleotides) can interfere with the assay through reagent consumption. Products must be free of bacterial DNA. Narrow quantification range: 5-150 pg/well.

SAMPLE PREPARATION

The concentration of residual host-cell DNA may vary depending on the type of biological product and the DNA clearance capacity of the manufacturing process.

Depending on the sample matrix, pretreatment of the sample may be necessary to ensure appropriate recovery of the residual host-cell DNA.

When analysing highly purified protein samples such as recombinant proteins or monoclonal antibodies, simple digestion with proteinase or affinity chromatography may be sufficient to recover the residual host-cell DNA. For more complex matrices such as viral vaccines and viral vectors, an additional virus lysis step may be required to release the residual host-cell DNA from the viral particles.

The immunoenzymatic method is especially sensitive to interference from proteins. This can be avoided by performing an initial pretreatment step, which may include digestion with proteinase K and sodium dodecyl sulfate (SDS). This step may suffice to recover the residual host-cell DNA. However, in other cases, the residual host-cell DNA may be bound to the sample components, and/or soluble interfering substances may be present, in which case it may be necessary to extract the residual host-cell DNA from the sample.

The DNA can be extracted using protocols which have demonstrated a satisfactory recovery rate during spiking experiments. Several suitable methods exist, including DNA precipitation or DNA-specific binding to a matrix (e.g. magnetic beads or silica columns). Commercial kits can be used to extract residual host-cell DNA samples. Some of these kits use a chaotrope (sodium iodide) and a detergent (sodium lauroylsarcosinate) to disrupt the association between the residual host-cell DNA and the sample components. The residual host-cell DNA in the sample is then recovered by co-precipitation with a carrier molecule such as glycogen in the presence of ethanol or 2-propanol. Several independent extraction procedures may be required, depending on the reproducibility of the spike recovery. Negative controls must be included in each extraction procedure. In some cases, dilution of the samples may be recommended to reduce the matrix effect. A correction factor may also be applied to take into account the recovery rate of the spike.

METHOD A – REAL-TIME QUANTITATIVE PCR (QPCR)

This method can be used to quantify a cellular DNA target sequence from a variety of samples. For the quantification of residual host-cell DNA, qPCR targeting either a stable sequence within a highly conserved host-cell region or targeting repetitive elements to enhance the sensitivity of the test can be used. When repetitive elements are targeted, it may be difficult to eliminate potential background noise due to environmental DNA (e.g. when using Alu human sequences). The specificity of the qPCR method must be established during the validation studies by demonstrating the absence of cross-reactivity with unrelated sequences.

Alternatively, digital PCR methods may be used.

qPCR amplification

The detection and quantification of residual host-cell DNA by qPCR may involve the use of either a non-specific fluorescent dye that intercalates with any double-stranded DNA, or sequence-specific DNA probes. The qPCR principle described in general chapter *2.6.21. Nucleic acid amplification techniques* applies.

The number of cycles required for the fluorescent measurement to exceed a threshold value (Ct or Cp) correlates to the starting amount of residual host-cell DNA in the sample.

If several extractions are performed, the resulting samples must be analysed at an appropriate dilution.

PCR negative controls are used.

A standard curve is plotted using serial dilutions of host-cell genomic DNA in order to allow residual host-cell DNA levels in biological products to be determined based on their Ct or Cp values. The use of carefully characterised representative genomic DNA extracted from the cells used for the production of the biological product is recommended for the preparation of the standard.

The same methodology is applied for residual host-cell DNA size evaluation. At least 2 sets of primers can be designed to amplify overlapping fragments of different sizes in the target sequence.

Suitability criteria

Control samples In order to control the risk of contamination and to ensure adequate sensitivity, each PCR assay includes the following controls:

- *a negative control for qPCR* and *a negative control for extraction*, composed of a sample of a suitable matrix already proven to be free of the target sequence(s);
- *a positive control for qPCR*, which contains a defined number of target sequence copies or a defined DNA concentration which is determined individually for each assay system;
- *a control for extraction*, typically an internal control added to the test material as a defined concentration or number of target-sequence copies. In this case, the amplicons must be clearly discernible and may be detected in a separate qPCR. Alternatively, an external control consisting of test sample spiked with a well-characterised level of genomic DNA may be used.

Extraction recovery must fall within predetermined values based on the performance of the assay as demonstrated during assay validation.

Genomic DNA standard curve The standard curve is linear over the chosen range.

The coefficient of determination R^2 associated with the standard curve must be greater or equal to 0.98. The PCR efficiency falls within pre-established limits.

The coefficient of variation for the different extracts or replicates is not higher than a predefined criterion.

Calculation

If several extractions are performed, each extracted sample is analysed individually. The residual host-cell DNA content is calculated from the genomic standard curve by averaging the values obtained for the different extractions or replicates.

A correction factor may also be applied to take into account the recovery rate for total DNA quantification in the samples.

For the characterisation of residual host-cell DNA size, the distribution of the overlapping fragments of different sizes is calculated as the ratio of the number of copies for each amplicon size to the number of copies of the smallest amplicon size.

METHOD B – IMMUNOENZYMATIC METHOD

The immunoenzymatic method is a non-specific technique for the quantification of residual host-cell DNA (regardless of its origin). It is therefore also a total DNA assay, and consequently, it is not only critical to avoid contamination through environmental DNA, but all materials and reagents used must be DNA-free. The samples to be tested must be free of microbial contamination and all samples, controls and standards must be processed under controlled conditions until the denaturation step.

By design, the method detects single-stranded DNA.

Principle

This total DNA assay consists of 4 steps:

- *denaturation and formation of complexes*, where the DNA is denatured into single-stranded DNA by heating the sample. The denatured DNA is mixed with a single reagent that contains a single-stranded DNA-binding protein conjugated to streptavidin and a monoclonal anti-DNA antibody conjugated to urease. The DNA-binding protein and the monoclonal antibody are specific for single-stranded DNA but are not sequence-specific. The liquid phase, in the presence of streptavidin, facilitates the formation of a complex with the single-stranded DNA from the sample.
- *filtration*, where the complex is filtered through a biotinylated nitrocellulose membrane. The biotin in the membrane captures the complexes by binding to streptavidin. The membrane is washed to remove any unbound reagents. Non-specific binding is avoided by the use of an albumin-coated nitrocellulose membrane.
- *detection*, where the membrane is placed in a reader, which contains a urea solution that reacts with the urease in the DNA complex and produces ammonia. The associated change in pH is measured by a potentiometric sensor in µV/s and is directly proportional to the amount of DNA in the sample.
- *analysis*, where the raw data from the sample and from the standard curve are analysed using appropriate software to determine the residual host-cell DNA content in the sample.

All samples and negative controls are tested spiked and unspiked. The spike solution (1000 pg/mL) is prepared by dilution of a concentrated standard (calf thymus DNA) at 5000 pg/mL.

Suitability criteria

Control samples

- the amount of DNA in the positive control falls within the range indicated on the batch certificate provided by the supplier;

— spike recovery in the negative control is between 80 per cent and 120 per cent.

Samples

— when several replicates are analysed, the coefficient of variation for the different replicates is not higher than a predefined criterion;
— spike recovery is between 80 per cent and 120 per cent.

Calculation

The content of residual host-cell DNA is calculated in picograms per millilitre using the following expression:

$$\frac{ID \times (C - A)}{V}$$

ID = ratio for dilution and sampling;
C = raw mean value (in picograms per tube) for the test tubes containing the diluted sample;
A = raw mean value (in picograms per tube) for the test tubes containing the negative control;
V = volume in the test tube, in millilitres (usually 0.5 mL per tube).

Where necessary, this result may be corrected by the extraction recovery (e.g. mean recovery for a given product).

P. Determination of Bactericidal, Fungicidal or Yeasticidal Activity of Antiseptic Medicinal Products

(Ph. Eur. method 5.1.11)

This general chapter describes a test that can be used for the determination of antimicrobial activity in antiseptic medicinal products that are miscible with water and intended for administration by direct contact with the skin or mucous membranes. The extent of testing is dependent on the declared antimicrobial activity of the product.

The test determines whether a product exhibits bactericidal, fungicidal or yeasticidal activity and complies with an established specification for such activity.

This test cannot replace or confirm the assessment of the clinical efficacy of such preparations.

1 PRINCIPLE

Antimicrobial activity is determined by adding test suspensions of micro-organisms (bacteria, fungi or yeasts, separately) to the sample antiseptic product. The mixture is maintained at 33 ± 1 °C for contact times of 5 min for bactericidal activity and 15 min for fungicidal or yeasticidal activity. Additional contact times may be chosen, according to the stated use of the antiseptic medicinal product. At the end of the contact time, an aliquot is taken and the antimicrobial activity in this aliquot is immediately stopped by a validated method. 2 methods are available: dilution-neutralisation and membrane filtration.

The procedure is validated to verify its ability to demonstrate the required reduction in the count of viable micro-organisms by the use of appropriate controls.

2 TEST MICRO-ORGANISMS AND GROWTH CONDITIONS

Prepare standardised stable suspensions of test strains as stated in section 2-1. Seed-lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the microbial test strains separately as described in Table 5.1.11.-1.

Table 5.1.11.-1. – *Test micro-organisms and growth conditions*

Strains for bactericidal activity testing	
Staphylococcus aureus	such as ATCC 6538, NCIMB 9518, CIP 4.83, NBRC 13276
Enterococcus hirae	such as ATCC 10541, NCIMB 8192, CIP 58.55, DSM 3320
Escherichia coli	such as NCIMB 10083, CIP 54.117, NCTC 10538, DSM 11250
Pseudomonas aeruginosa	such as ATCC 15442, NCIMB 8626, CIP 103467, NBRC 13275
Bacterial growth conditions	
Casein soya bean digest agar or casein soya bean digest broth - for preparation of test strains: 30-35 °C, 18-24 h and subculture at least twice - for testing of the product and validation of the test: 30-35 °C, ≤ 3 days	number of CFU in test suspension: 1-5 × 10^8 CFU/mL
Strain for yeasticidal activity testing	
Candida albicans	such as ATCC 10231, NCPF 3179, CIP 48.72, NBRC 1594
Yeast growth conditions	
Sabouraud-dextrose agar or Sabouraud-dextrose broth - for preparation of test strains: 20-25 °C, 2-3 days and subculture at least twice - for testing of the product and validation of the test: 20-25 °C, ≤ 5 days	number of CFU in test suspension: 1-5 × 10^7 CFU/mL
Strains for fungicidal activity testing	
Candida albicans	such as ATCC 10231, NCPF 3179, CIP 48.72, NBRC 1594
Aspergillus brasiliensis	such as ATCC 16404, IMI 149007, CIP 1431.83, NBRC 9455
Fungal growth conditions	
Sabouraud-dextrose agar or Sabouraud-dextrose broth - for preparation of test suspension of *C. albicans*: 20-25 °C, 2-3 days - for preparation of test suspension of *A. brasiliensis* spores: 20-25 °C, at least 5 days until good sporulation - for testing of the product and validation of the test with *C. albicans* and *A. brasiliensis*: 20-25 °C, ≤ 5 days	number of CFU in test suspension: 1-5 × 10^7 CFU/mL

The recommended solutions and media are described in general chapter *2.6.13*. Purified water is used. All reagents are sterile prior to use.

The test for bactericidal, fungicidal or yeasticidal activity is performed with the designated strains as described in Table 5.1.11.-1. In addition to these micro-organisms, it may be necessary to add other bacterial or fungal strains that represent the indications of the antiseptic medicinal product tested.

Single-strain challenges are used. The counts are performed in duplicate and the arithmetic mean of the results is calculated and expressed in CFU/mL.

2-1 PREPARATION OF TEST SUSPENSION

For harvesting the micro-organisms use a sufficient volume of a 9 g/L solution of *sodium chloride R* (for bacteria and *C. albicans*) or a solution containing 9 g/L of *sodium chloride R* and 0.5 g/L of *polysorbate 80 R* (for *A. brasiliensis*), to obtain a test suspension with the number of CFU described in Table 5.1.11.-1. Use the suspension within 2 h or within 24 h if stored at 2-8 °C.

2-2 PREPARATION OF ANTISEPTIC PRODUCT TEST SOLUTION

The concentration of the antiseptic product test solution shall be, if possible, 1.25 times the in-use test concentration because it is diluted to 80 per cent during the test and the method validation.

2-3 NEUTRALISING AGENTS

Neutralising agents are used to neutralise the antimicrobial activity of the antiseptic product. The common neutralising agents are listed in Table 2.6.12.-2 of general chapter *2.6.12. Microbiological examination of non-sterile products: microbial enumeration tests*. The neutralisation time is not less than 10 s and not more than 60 s.

3 METHODS

Prior to testing, equilibrate the temperature of all reagents to 33 ± 1 °C.

3-1 DILUTION-NEUTRALISATION METHOD

Transfer 1.0 mL of a 3 g/L solution of *bovine albumin R* into a tube, add 1.0 mL of the test suspension and maintain at 33 ± 1 °C for 2 min. Add 8.0 mL of the antiseptic product test solution and maintain at 33 ± 1 °C for the chosen contact time. Then, take a 1.0 mL sample of the test mixture and transfer into a tube containing 1.0 mL of *water R* and 8.0 mL of the neutralising agent and maintain at 33 ± 1 °C for the appropriate neutralisation time. Take 1.0 mL of the neutralised test mixture, in duplicate, and inoculate using the pour-plate or surface-spread method. For incubation conditions, see Table 5.1.11.-1. After incubation, perform the count.

3-1-1 Suitability of the test/controls

For all methods, prepare a validation suspension containing 100-1000 CFU of the test micro-organisms per millilitre.

3-1-1-1 Experimental conditions control

Transfer 1.0 mL of a 3 g/L solution of *bovine albumin R* into a tube, add 1.0 mL of the validation suspension and maintain at 33 ± 1 °C for 2 min. Add 8.0 mL of *water R* and maintain at 33 ± 1 °C for the chosen contact time. Take 1.0 mL of this mixture, in duplicate, and inoculate using the pour-plate or surface-spread method. For incubation conditions, see Table 5.1.11.-1. After incubation, perform the count. The number of CFU recovered following incubation is not less than 0.5 × (number of CFU in the validation suspension)/10.

3-1-1-2 Neutralising agent control

Transfer 1.0 mL of a 3 g/L solution of *bovine albumin R* into a tube, add 1.0 mL of the validation suspension and 8.0 mL of the neutralising agent used in the test and maintain at 33 ± 1 °C for the appropriate neutralisation time. Take 1.0 mL of this mixture, in duplicate, and inoculate using the pour-plate or surface-spread method. For incubation conditions, see Table 5.1.11.-1. After incubation, perform the count. The number of CFU recovered following incubation is not less than 0.5 × (number of CFU in the validation suspension)/10.

3-1-1-3 Dilution-neutralisation method control

Transfer 1.0 mL of a 3 g/L solution of *bovine albumin R* into a tube, add 1.0 mL of a 9 g/L solution of *sodium chloride R* and 8.0 mL of the product test solution and maintain at 33 ± 1 °C for the chosen contact time. Transfer 1.0 mL of this mixture into a tube containing 8.0 mL of the neutralising agent and maintain at 33 ± 1 °C for the appropriate neutralisation time. Then add 1.0 mL of the validation suspension and mix. After 30 min, take a sample of 1.0 mL of the mixture, in duplicate, and inoculate using the pour-plate or surface-spread method. For incubation conditions, see Table 5.1.11.-1. After incubation, perform the count. The number of CFU recovered following incubation is not less than 0.5 × (number of CFU in the validation suspension)/10.

3-2 MEMBRANE FILTRATION METHOD

Proceed as described in section 3-1, carrying out immediately the filtration step in place of the neutralisation step.

Use membrane filters having a nominal pore size not greater than 0.45 µm. The type of filter material is chosen such that the microbe-retaining efficiency is not affected by the components of the sample to be investigated. For each of the micro-organisms listed, a single membrane filter is used. Appropriately dilute 0.1 mL of the test solution and immediately filter the total volume, then rinse the membrane filter with an appropriate volume of the diluent. Perform the test in duplicate. For incubation conditions, see Table 5.1.11.-1. After incubation, perform the count.

3-2-1 Verification of the selected experimental conditions and of the membrane filtration method

3-2-1-1 Experimental conditions control

Proceed as described in section 3-1-1-1, except at the end of the contact time, take the sample in duplicate, and transfer into a separate membrane filtration apparatus. Filter immediately and then transfer each of the membrane filters to the surface of separate plates. For incubation conditions, see Table 5.1.11.-1. After incubation, perform the count. The number of CFU recovered following incubation is not less than 0.5 × (number of CFU in the validation suspension)/10.

3-2-1-2 Membrane filtration method control

Proceed as described in section 3-1-1-3, except at the end of the chosen contact time, take that sample in duplicate, and transfer into a separate membrane filtration apparatus. Filter and rinse as described in section 3-2, then cover the membranes with rinsing liquid and add a sample of the validation suspension. Filter again and transfer each of the membrane filters to the surface of separate plates. For incubation conditions, see Table 5.1.11.-1. After incubation, perform the count. The number of CFU recovered following incubation is not less than 0.5 × (number of CFU in the validation suspension)/10.

4 ACCEPTANCE CRITERIA

Unless otherwise justified and authorised, the preparation has a:

- bactericidal activity if the defined number of CFU is reduced by at least 5 $\log_{10}$;
- fungicidal activity if the defined number of CFU is reduced by at least 4 $\log_{10}$;
- yeasticidal activity if the defined number of CFU is reduced by at least 4 $\log_{10}$.

Appendix XV

Production and Testing of Vaccines

A. Terminology used in Monographs on Biological Products

(Ph. Eur. general texts 5.2.1)

Terminology: Vaccines

For some items, alternative terms commonly used in connection with veterinary vaccines are shown in parenthesis.

Seed-lot system
A seed-lot system is a system according to which successive batches of a product are derived from the same master seed lot. For routine production, a working seed lot may be prepared from the master seed lot. The origin and the passage history of the master seed lot and the working seed lot are recorded.

Master seed lot
A culture of a micro-organism distributed from a single bulk into containers and processed together in a single operation in such a manner as to ensure uniformity and stability and to prevent contamination. A master seed lot in liquid form is usually stored at or below −70 °C. A freeze-dried master seed lot is stored at a temperature known to ensure stability.

Working seed lot
A culture of a micro-organism derived from the master seed lot and intended for use in production. Working seed lots are distributed into containers and stored as described above for master seed lots.

Cell-bank system (Cell-seed system)
A system whereby successive final lots (batches) of a product are manufactured by culture in cells derived from the same master cell bank (master cell seed). A number of containers from the master cell bank (master cell seed) are used to prepare a working cell bank (working cell seed). The cell-bank system (cell-seed system) is validated for the highest passage level achieved during routine production.

Master cell bank (Master cell seed)
A culture of cells distributed into containers in a single operation, processed together and stored in such a manner as to ensure uniformity and stability and to prevent contamination. A master cell bank (master cell seed) is usually stored at −70 °C or lower.

Working cell bank (Working cell seed)
A culture of cells derived from the master cell bank (master cell seed) and intended for use in the preparation of production cell cultures. The working cell bank (working cell seed) is distributed into containers, processed and stored as described for the master cell bank (master cell seed).

Primary cell cultures
Cultures of cells obtained by trypsination of a suitable tissue or organ. The cells are essentially identical to those of the tissue of origin and are no more than 5 *in vitro* passages from the initial preparation from the animal tissue.

Cell lines
Cultures of cells that have a high capacity for multiplication *in vitro*. In diploid cell lines, the cells have essentially the same characteristics as those of the tissue of origin.
In continuous cell lines, the cells are able to multiply indefinitely in culture and may be obtained from healthy or tumoral tissue. Some continuous cell lines have oncogenic potential under certain conditions.

Production cell culture
A culture of cells intended for use in production; it may be derived from one or more containers of the working cell bank (working cell seed) or it may be a primary cell culture.

Control cells
A quantity of cells set aside, at the time of virus inoculation, as uninfected cell cultures. The uninfected cells are incubated under similar conditions to those used for the production cell cultures.

Single harvest
Material derived on one or more occasions from a single production cell culture inoculated with the same working seed lot or a suspension derived from the working seed lot, incubated, and harvested in a single production run.

Monovalent pooled harvest
Pooled material containing a single strain or type of micro-organism or antigen and derived from a number of eggs, cell culture containers etc. that are processed at the same time.

Final bulk vaccine
Material that has undergone all the steps of production except for the final filling. It consists of one or more monovalent pooled harvests, from cultures of one or more species or types of micro-organism, after clarification, dilution or addition of any adjuvant or other auxiliary substance. It is treated to ensure its homogeneity and is used for filling the containers of one or more final lots (batches).

Final lot (Batch)
A collection of closed, final containers or other final dosage units that are expected to be homogeneous and equivalent with respect to risk of contamination during filling or preparation of the final product. The dosage units are filled, or otherwise prepared, from the same final bulk vaccine, freeze-dried together (if applicable) and closed in one continuous working session. They bear a distinctive number or code identifying the final lot (batch). Where a final bulk vaccine is filled and/or freeze-dried on several separate sessions, there results a related set of final lots (batches) that are usually identified by the use of a common part in the distinctive number or code; these related final lots (batches) are sometimes referred to as sub-batches, sub-lots or filling lots.

Combined vaccine
A multicomponent preparation formulated so that different antigens are administered simultaneously. The different antigenic components are intended to protect against different strains or types of the same organism and/or different organisms. A combined vaccine may be supplied by the manufacturer either as a single liquid or freeze-dried preparation or as several constituents with directions for admixture before use.

B. Aluminium in Adsorbed Vaccines

(Ph. Eur. method 2.5.13)

Homogenise the preparation to be examined and transfer a suitable quantity, presumed to contain 5 mg to 6 mg of aluminium, to a 50 mL combustion flask. Add 1 mL of *sulfuric acid R*, 0.1 mL of *nitric acid R* and some glass beads. Heat the solution until thick, white fumes are evolved.

If there is charring at this stage add a few more drops of *nitric acid R* and continue boiling until the colour disappears. Allow to cool for a few minutes, carefully add 10 mL of *water R* and boil until a clear solution is obtained. Allow to cool, add 0.05 mL of *methyl orange solution R* and neutralise with *strong sodium hydroxide solution R* (6.5 mL to 7 mL). If a precipitate forms dissolve it by adding, dropwise, sufficient *dilute sulfuric acid R*. Transfer the solution to a 250 mL conical flask, rinsing the combustion flask with 25 mL of *water R*. Add 25.0 mL of *0.02 M sodium edetate*, 10 mL of *acetate buffer solution pH 4.4 R* and a few glass beads and boil gently for 3 min. Add 0.1 mL of *pyridylazonaphthol solution R* and titrate the hot solution with *0.02 M copper sulfate* until the colour changes to purplish-brown. Carry out a blank titration omitting the vaccine.

1 mL of *0.02 M sodium edetate* is equivalent to 0.5396 mg of Al.

C. Calcium in Adsorbed Vaccines

(Ph. Eur. method 2.5.14)

All solutions used for this test must be prepared using water R.

Determine the calcium by atomic emission spectrometry (*2.2.22, Method I*). Homogenise the preparation to be examined. To 1.0 mL add 0.2 mL of *dilute hydrochloric acid R* and dilute to 3.0 mL with *water R*. Measure the absorbance at 620 nm.

D. Free Formaldehyde

(Ph. Eur. method 2.4.18)

Use method A, unless otherwise prescribed. Method B is suitable for vaccines where sodium metabisulfite has been used to neutralise excess formaldehyde.

METHOD A

For vaccines for human use, prepare a 1 in 10 dilution of the vaccine to be examined. For bacterial toxoids for veterinary use, prepare a 1 in 25 dilution of the vaccine to be examined.

To 1 mL of the dilution, add 4 mL of *water R* and 5 mL of *acetylacetone reagent R1*. Place the tube in a water-bath at 40 °C for 40 min. Examine the tubes down their vertical axes. The solution is not more intensely coloured than a standard, prepared at the same time and in the same manner, using 1 mL of a dilution of *formaldehyde solution R* containing 20 µg of formaldehyde (CH_2O) per millilitre, instead of the dilution of the vaccine to be examined.

METHOD B

Test solution Prepare a 1 in 200 dilution of the vaccine to be examined with *water R*. If the vaccine is an emulsion, prepare an equivalent dilution using the aqueous phase separated by a suitable procedure (see below). If one of the methods described below is used for separation of the aqueous phase, a 1 in 20 dilution of the latter is used.

Reference solutions Prepare solutions containing 0.25 g/L, 0.50 g/L, 1.00 g/L and 2.00 g/L of CH_2O by dilution of *formaldehyde solution R* with *water R*. Prepare a 1 in 200 dilution of each solution with *water R*.

To 0.5 mL of the test solution and of each of the reference solutions in test-tubes, add 5.0 mL of a freshly prepared 0.5 g/L solution of *methylbenzothiazolone hydrazone hydrochloride R*. Close the tubes, shake and allow to stand for 60 min. Add 1 mL of ferric chloride-sulfamic acid reagent R and allow to stand for 15 min. Measure the absorbance (*2.2.25*) of the solutions at 628 nm. Calculate the content of formaldehyde in the vaccine to be examined from the calibration curve established using the reference solutions. The test is invalid if the correlation coefficient (r) of the calibration curve is less than 0.97.

Emulsions If the vaccine to be examined is an emulsion, the aqueous phase is separated using a suitable procedure and used for preparation of the test solution. The following procedures have been found suitable.

(a) Add 1.0 mL of the vaccine to be examined to 1.0 mL of *isopropyl myristate R* and mix. Add 1.3 mL of *1 M hydrochloric acid*, 2.0 mL of *chloroform R* and 2.7 mL of a 9 g/L solution of *sodium chloride R*. Mix thoroughly. Centrifuge at 15 000 *g* for 60 min. Transfer the aqueous phase to a 10 mL volumetric flask and dilute to volume with *water R*. If this procedure fails to separate the aqueous phase, add 100 g/L of *polysorbate 20 R* to the sodium chloride solution and repeat the procedure but centrifuge at 22 500 *g*.

(b) Add 1.0 mL of the vaccine to be examined to 1.0 mL of a 100 g/L solution of *sodium chloride R* and mix. Centrifuge at 1000 *g* for 15 min. Transfer the aqueous phase to a 10 mL volumetric flask and dilute to volume with *water R*.

(c) Add 1.0 mL of the vaccine to be examined to 2.0 mL of a 100 g/L solution of *sodium chloride R* and 3.0 mL of *chloroform R* and mix. Centrifuge at 1000 *g* for 5 min. Transfer the aqueous phase to a 10 mL volumetric flask and dilute to volume with *water R*.

E. Phenol in Immunosera (Antisera) and Vaccines

(Ph. Eur. method 2.5.15)

Homogenise the preparation to be examined. Dilute an appropriate volume with *water R* so as to obtain a solution presumed to contain 15 µg of phenol per millilitre. Prepare a series of reference solutions with *phenol R* containing 5 µg, 10 µg, 15 µg, 20 µg and 30 µg of phenol per millilitre respectively. To 5 mL of the solution to be examined and to 5 mL of each of the reference solutions respectively, add 5 mL of *buffer solution pH 9.0 R*, 5 mL of *aminopyrazolone solution R* and 5 mL of *potassium ferricyanide solution R*. Allow to stand for 10 min and measure the intensity of colour at 546 nm.

Plot the calibration curve and calculate the phenol content of the preparation to be examined.

F. Neurovirulence

Test for Neurovirulence of Live Virus Vaccines

(Ph. Eur. method 2.6.18)

For each test, use not fewer than ten monkeys that are seronegative for the virus to be tested. For each monkey, inject not more than 0.5 mL of the material to be examined into the thalamic region of each hemisphere, unless otherwise prescribed. The total amount of virus inoculated in each monkey must be not less than the amount contained in the recommended single human dose of the vaccine. As a check against the introduction of wild neurovirulent virus, keep a

group of not fewer than four control monkeys as cage-mates or in the immediate vicinity of the inoculated monkeys. Observe the inoculated monkeys for 17 to 21 days for symptoms of paralysis and other evidence of neurological involvement; observe the control monkeys for the same period plus 10 days. Animals that die within 48 h of injection are considered to have died from non-specific causes and may be replaced. The test is not valid if: more than 20 per cent of the inoculated monkeys die from nonspecific causes; serum samples taken from the control monkeys at the time of inoculation of the test animals and 10 days after the latter are euthanised show evidence of infection by wild virus of the type to be tested or by measles virus. At the end of the observation period, carry out autopsy and histopathological examinations of appropriate areas of the brain for evidence of central nervous system involvement. The material complies with the test if there is no unexpected clinical or histopathological evidence of involvement of the central nervous system attributable to the inoculated virus.

G. Composition of Polysaccharide Vaccines

Protein

(Ph. Eur. method 2.5.16)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Place 1 mL of the solution in a glass tube and add 0.15 mL of a 400 g/L solution of *trichloroacetic acid R*. Shake, allow to stand for 15 min, centrifuge for 10 min at 5000 r/min and discard the supernatant. Add 0.4 mL of *0.1 M sodium hydroxide* to the centrifugation residue.

Reference solutions Dissolve 0.100 g of *bovine albumin R* in 100 mL of *0.1 M sodium hydroxide* (stock solution containing 1 g of protein per litre). Dilute 1 mL of the stock solution to 20 mL with *0.1 M sodium hydroxide* (working dilution 1: 50 mg of protein per litre). Dilute 1 mL of the stock solution to 4 mL with *0.1 M sodium hydroxide* (working dilution 2: 250 mg of protein per litre). Place in 6 glass tubes 0.10 mL, 0.20 mL and 0.40 mL of working dilution 1 and 0.15 mL, 0.20 mL and 0.25 mL of working dilution 2. Make up the volume in each tube to 0.40 mL using *0.1 M sodium hydroxide*.

Prepare a blank using 0.40 mL of *0.1 M sodium hydroxide*.

Add 2 mL of *cupri-tartaric solution R3* to each tube, shake and allow to stand for 10 min. Add to each tube 0.2 mL of a mixture of equal volumes of *phosphomolybdotungstic reagent R* and *water R*, prepared immediately before use. Stopper the tubes, mix by inverting and allow to stand in the dark for 30 min. The blue colour is stable for 60 min. If necessary, centrifuge to obtain clear solutions.

Measure the absorbance (*2.2.25*) of each solution at 760 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbances of the 6 reference solutions and the corresponding protein contents and read from the curve the content of protein in the test solution.

Nucleic Acids

(Ph. Eur. method 2.5.17)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*.

Dilute the test solution if necessary to obtain an absorbance value suitable for the instrument used. Measure the absorbance (*2.2.25*) at 260 nm using *water R* as the compensation liquid.

The absorbance of a 1 g/L solution of nucleic acid at 260 nm is 20.

Phosphorus

(Ph. Eur. method 2.5.18)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volume used in the test (1 mL) contains about 6 µg of phosphorus. Transfer 1.0 mL of the solution to a 10 mL ignition tube.

Reference solutions Dissolve 0.2194 g of *potassium dihydrogen phosphate R* in 500 mL of *water R* to give a solution containing the equivalent of 0.1 mg of phosphorus per millilitre. Dilute 5.0 mL of the solution to 100.0 mL with *water R*. Introduce 0.5 mL, 1.0 mL and 2.0 mL of the dilute solution into 3 ignition tubes.

Prepare a blank solution using 2.0 mL of *water R* in an ignition tube.

To all the tubes add 0.2 mL of *sulfuric acid R* and heat in an oil bath at 120 °C for 1 h and then at 160 °C until white fumes appear (about 1 h). Add 0.1 mL of *perchloric acid R* and heat at 160 °C until the solution is decolorised (about 90 min). Cool and add to each tube 4 mL of *water R* and 4 mL of *ammonium molybdate reagent R*. Heat in a water-bath at 37 °C for 90 min and cool. Adjust the volume to 10.0 mL with *water R*. The blue colour is stable for several hours.

Measure the absorbance (*2.2.25*) of each solution at 820 nm using the blank solution as the compensation liquid. Draw a calibration curve with the absorbances of the 3 reference solutions as a function of the quantity of phosphorus in the solutions and read from the curve the quantity of phosphorus in the test solution.

O-Acetyl Groups

(Ph. Eur. method 2.5.19)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 30 µg to 600 µg of acetylcholine chloride (*O*-acetyl). Introduce 0.3 mL, 0.5 mL and 1.0 mL in duplicate into 6 tubes (3 reaction solutions and 3 correction solutions).

Reference solutions Dissolve 0.150 g of *acetylcholine chloride R* in 10 mL of *water R* (stock solution containing 15 g of acetylcholine chloride per litre). Immediately before use, dilute 1 mL of the stock solution to 50 mL with *water R* (working dilution 1: 300 µg of acetylcholine chloride per millilitre). Immediately before use, dilute 1 mL of the stock solution to 25 mL with *water R* (working dilution 2: 600 µg of acetylcholine chloride per millilitre). Introduce 0.1 mL and 0.4 mL of working dilution 1 in duplicate (reaction and correction solutions) into 4 tubes and 0.6 mL and 1.0 mL of working dilution 2 in duplicate (reaction and correction solutions) into another 4 tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Add 1.0 mL of a 4 M solution of hydrochloric acid prepared from *hydrochloric acid R* to each of the correction tubes and to the blank. Add 2.0 mL of *alkaline hydroxylamine solution R* to each tube. Allow the reaction to proceed for exactly 2 min and add 1.0 mL of the 4 M solution of hydrochloric acid to each of the reaction tubes. To each tube, add 1.0 mL of a 100 g/L solution of *ferric chloride R* in a 0.1 M solution of hydrochloric acid prepared from *hydrochloric acid R*, stopper the tubes and shake vigorously to remove bubbles.

Measure the absorbance (*2.2.25*) of each solution at 540 nm using the blank as the compensation liquid. For each reaction solution, subtract the absorbance of the corresponding correction solution. Draw a calibration curve from the corrected absorbances for the 4 reference solutions and the corresponding content of acetylcholine chloride and read from the curve the content of acetylcholine chloride in the test solution for each volume tested. Calculate the mean of the 3 values.

1 mole of acetylcholine chloride (181.7 g) is equivalent to 1 mole of *O*-acetyl (43.05 g).

Hexosamines

(Ph. Eur. method 2.5.20)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 125 µg to 500 µg of glucosamine (hexosamine). Introduce 1.0 mL of the diluted solution into a graduated tube.

Reference solutions Dissolve 60 mg of *glucosamine hydrochloride R* in 100 mL of *water R* (stock solution containing 0.500 g of glucosamine per litre). Introduce 0.25 mL, 0.50 mL, 0.75 mL, and 1.0 mL of the working dilution into 4 graduated tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Add 1 mL of a solution of *hydrochloric acid R* (292 g/L) to each tube. Stopper the tubes and place in a water-bath for 1 h. Cool to room temperature. Add to each tube 0.05 mL of a 5 g/L solution of *thymolphthalein R* in *alcohol R*; add a solution of *sodium hydroxide R* (200 g/L) until a blue colour is obtained and then *1 M hydrochloric acid* until the solution is colourless. Dilute the volume in each tube to 10 mL with *water R* (neutralised hydrolysates).

In a second series of 10 mL graduated tubes, place 1 mL of each neutralised hydrolysate. Add 1 mL of acetylacetone reagent (a mixture, prepared immediately before use, of 1 volume of *acetylacetone R* and 50 volumes of a 53 g/L solution of *anhydrous sodium carbonate R*) to each tube. Stopper the tubes and place in a water-bath at 90 °C for 45 min. Cool to room temperature. Add to each tube 2.5 mL of *alcohol R* and 1.0 mL of dimethylaminobenzaldehyde solution (immediately before use dissolve 0.8 g of *dimethylaminobenzaldehyde R* in 15 mL of *alcohol R* and add 15 mL of *hydrochloric acid R*) and dilute the volume in each tube to 10 mL with *alcohol R*. Stopper the tubes, mix by inverting and allow to stand in the dark for 90 min. Measure the absorbance (*2.2.25*) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 4 reference solutions and the corresponding content of hexosamine and read from the curve the quantity of hexosamine in the test solution.

Methylpentoses

(Ph. Eur. method 2.5.21)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2 µg to 20 µg of rhamnose (methylpentoses). Introduce 0.25 mL, 0.50 mL and 1.0 mL of the diluted solution into 3 tubes.

Reference solutions Dissolve 0.100 g of *rhamnose R* in 100 mL of *water R* (stock solution containing 1 g of methylpentose per litre). Immediately before use, dilute 1 mL of the stock solution to 50 mL with *water R* (working dilution: 20 mg of methylpentose per litre). Introduce 0.10 mL, 0.25 mL, 0.50 mL, 0.75 mL and 1.0 mL of the working dilution into 5 tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 4.5 mL of a cooled mixture of 1 volume of *water R* and 6 volumes of *sulfuric acid R*. Warm the tubes to room temperature and place in a water-bath for a few minutes. Cool to room temperature. Add to each tube 0.10 mL of a 30 g/L solution of *cysteine hydrochloride R*, prepared immediately before use. Shake and allow to stand for 2 h.

Measure the absorbance (*2.2.25*) of each solution at 396 nm and at 430 nm using the blank as compensation liquid. For each solution, calculate the difference between the absorbance measured at 396 nm and that measured at 430 nm. Draw a calibration curve from the absorbance differences for the 5 reference solutions and the corresponding content of methylpentose and read from the curve the quantity of methylpentose in the test solution for each volume tested. Calculate the mean of the 3 values.

Uronic Acids

(Ph. Eur. method 2.5.22)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 4 µg to 40 µg of glucuronic acid (uronic acids). Introduce 0.25 mL, 0.50 mL and 1.0 mL of the diluted solution into 3 tubes.

Reference solutions Dissolve 50 mg of *sodium glucuronate R* in 100 mL of *water R* (stock solution containing 0.4 g of glucuronic acid per litre). Immediately before use, dilute 5 mL of the stock solution to 50 mL with *water R* (working dilution: 40 mg of glucuronic acid per litre). Introduce 0.10 mL, 0.25 mL, 0.50 mL, 0.75 mL, and 1.0 mL of the working dilution into 5 tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 5.0 mL of *borate solution R*. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature. Add 0.20 mL of a 1.25 g/L solution of *carbazole R* in *ethanol R* to each tube. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature.

Measure the absorbance (*2.2.25*) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 5 reference solutions and the corresponding content of glucuronic acid and read from the curve the quantity of glucuronic acid in the test solution for each volume tested. Calculate the mean of the 3 values.

Sialic Acid

(Ph. Eur. method 2.5.23)

Test solution Transfer quantitatively the contents of one or several containers to a volumetric flask of a suitable volume that will give a solution with a known concentration of about 250 µg per millilitre of polysaccharide and dilute to volume with *water R*. Using a syringe, transfer 4.0 mL of this solution to a 10 mL ultrafiltration cell suitable for the passage of molecules of relative molecular mass less than 50 000. Rinse the syringe twice with *water R* and transfer the rinsings to the ultrafiltration cell. Carry out the ultrafiltration, with constant stirring, under *nitrogen R* at a pressure of about 150 kPa. Refill the cell with *water R* each time the volume of liquid in it has decreased to 1 mL and continue until 200 mL has been filtered and the remaining volume in the cell is about 2 mL. Using a syringe, transfer this residual liquid to a 10 mL volumetric flask. Wash the cell with 3 quantities, each of 2 mL, of *water R*, transfer the washings to the flask and dilute to 10.0 mL with *water R* (test solution). In each of 2 test-tubes place 2.0 mL of the test solution.

Reference solutions Use the reference solutions prescribed in the monograph.

Prepare 2 series of 3 test-tubes, place in the tubes of each series 0.5 mL, 1.0 mL and 1.5 mL respectively, of the reference solution corresponding to the type of vaccine to be examined and adjust the volume in each tube to 2.0 mL with *water R*.

Prepare blank solutions using 2.0 mL of *water R* in each of 2 test-tubes.

To all the tubes add 5.0 mL of *resorcinol reagent R*. Heat at 105 °C for 15 min, cool in cold water and transfer the tubes to a bath of iced water. To each tube add 5 mL of *isoamyl alcohol R* and mix thoroughly. Place in the bath of iced water for 15 min. Centrifuge the tubes and keep them in the bath of iced water until the examination by absorption spectrophotometry. Measure the absorbance (*2.2.25*) of each supernatant solution at 580 nm and 450 nm using *isoamyl alcohol R* as the compensation liquid. For each wavelength, calculate the absorbance as the mean of the values obtained with 2 identical solutions. Subtract the mean value for the blank solution from the mean values obtained for the other solutions.

Draw a graph showing the difference between the absorbances at 580 nm and 450 nm of the reference solutions as a function of the content of *N*-acetylneuraminic acid and read from the graph the quantity of *N*-acetylneuraminic acid (sialic acid) in the test solution.

Ribose

(Ph. Eur. method 2.5.31)

Test solution Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2.5 µg to 25 µg of ribose. Introduce 0.20 mL and 0.40 mL of the diluted solution into tubes in triplicate.

Reference solutions Dissolve 25 mg of *ribose R* in *water R* and dilute to 100.0 mL with the same solvent (stock solution containing 0.25 g/L of ribose). Immediately before use, dilute 1 mL of the stock solution to 10.0 mL with *water R* (working dilution: 25 mg/L of ribose). Introduce 0.10 mL, 0.20 mL, 0.40 mL, 0.60 mL, 0.80 mL and 1.0 mL of the working dilution into 6 tubes.

Prepare a blank using 2 mL of *water R*.

Make up the volume in each tube to 2 mL with *water R*. Shake. Add 2 mL of a 0.5 g/L solution of *ferric chloride R* in *hydrochloric acid R* to each tube. Shake. Add 0.2 mL of a 100 g/L solution of *orcinol R* in *ethanol R*. Place the tubes in a water-bath for 20 min. Cool in iced water. Measure the absorbance (*2.2.25*) of each solution at 670 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbance readings for the 6 reference solutions and the corresponding content of ribose and read from the curve the quantity of ribose in the test solution for each volume tested. Calculate the mean of the 3 values.

H. Chicken Flocks Free from Specified Pathogens for the Production and Quality Control of Vaccines

(Ph. Eur. method 5.2.2)

Where specified, chickens, embryos or cell cultures used for the production or quality control of vaccines are derived from eggs produced by chicken flocks free from specified pathogens (SPF). The SPF status of a flock is ensured by means of the system described below. The list of micro-organisms given is based on current knowledge and will be updated as necessary.

A flock is defined as a group of birds sharing a common environment and having their own caretakers who have no contact with non-SPF flocks. Once a flock is defined, no non-SPF birds are added to it.

Each flock is housed so as to minimise the risk of contamination. The facility in which the flock is housed must not be sited near to any non-SPF flocks of birds with the exception of flocks that are in the process of being established as SPF flocks and that are housed in facilities and conditions appropriate to SPF flocks. The SPF flock is housed within an isolator or in a building with filtered air under positive pressure. Appropriate measures are taken to prevent entry of rodents, wild birds, insects and unauthorised personnel.

Personnel authorised to enter the facility must have no contact with other birds or with agents potentially capable of infecting the flock. It is advisable for personnel to shower and change clothing or to wear protective clothing before entering the controlled facility.

Wherever possible, items taken into the facility are sterilised. In particular it is recommended that the feed is suitably treated to avoid introduction of undesirable micro-organisms and that water is at least of potable quality, for example from a chlorinated supply. No medication is administered to birds within the flock that might interfere with detection of any disease.

A permanent record is kept of the general health of the flock and any abnormality is investigated. Factors to be monitored include morbidity, mortality, general physical condition, feed consumption, daily egg production and egg quality, fertility

and hatchability. Records are maintained for a period of at least 5 years. Details of any deviation from normal in these performance parameters or detection of any infection are notified to the users of the eggs as soon as practicable.

The tests or combination of tests described below must have suitable specificity and sensitivity with respect to relevant serotypes of the viruses. Samples for testing are taken at random.

A positive result for chicken anaemia virus (CAV) does not necessarily exclude use of material derived from the flock, but live vaccines for use in birds less than 7 days old shall be produced using material from CAV-negative flocks. Inactivated vaccines for use in birds less than 7 days old may be produced using material from flocks that have not been shown to be free from CAV, provided it has been demonstrated that the inactivation process inactivates CAV.

ESTABLISHMENT OF AN SPF FLOCK

A designated SPF flock is derived from chickens shown to be free from vertically-transmissible agents listed in Table 5.2.2-1. This is achieved by testing of 2 generations prior to the designated SPF flock. A general scheme for the procedure to be followed in establishing and maintaining an SPF flock is shown diagrammatically in Table 5.2.2.-2. In order to establish a new SPF flock, a series of tests must be conducted on 3 generations of birds. All birds in the 1st generation must be tested at least once before the age of 20 weeks for freedom from avian leucosis group-antigen and tested by an enzyme immunoassay (EIA) or by virus neutralisation (VN) for freedom of antibodies to avian leucosis virus subtypes A, B and J. All birds must also be tested for freedom from antibodies to the vertically-transmissible agents listed in Table 5.2.2-1. From the age of 8 weeks the flock is tested for freedom from *Salmonella*. Clinical examination is carried out on the flock from 8 weeks of age and the birds must not exhibit any signs of infectious disease. The test methods to be used for these tests are given in the table and further guidance is also given in the section below on routine testing of designated SPF flocks. From 20 weeks of age, the flock is tested as described under Routine testing of designated SPF flocks. All stages of this testing regime are also applied to the subsequent 2 generations, except the testing of every bird before lay for vertically-transmissible agents. All test results must indicate freedom from pathogens in all 3 generations for the flock consisting of the 3rd generation to be designated as SPF.

SPF embryos derived from another designated SPF flock contained within a separate facility on the same site may be introduced. From 8 weeks of age, these replacement birds are regarded as a flock and are tested in accordance with test procedures described above.

INITIAL TESTING REQUIREMENTS FOR SUBSEQUENT GENERATIONS DERIVED FROM A DESIGNATED SPF FLOCK

Where a replacement flock is derived exclusively from a fully established SPF flock the new generation is tested prior to being designated as SPF. In addition to the tests for *Salmonella* and monitoring of the general health and performance of the flock, further specific testing from the age of 8 weeks is required. Tests are performed on two 5 per cent samples of the flock (minimum 10, maximum 200 birds) taken with an interval of at least 4 weeks between the ages of 12-16 weeks and 16-20 weeks.

All samples are collected and tested individually. Blood samples for antibody tests and suitable samples for testing for leucosis antigen are collected. The test methods to be used are as described under Routine testing of designated SPF flocks. Only when all tests have confirmed the absence of infection may the new generation be designated as SPF.

ROUTINE TESTING OF DESIGNATED SPF FLOCKS

General examination and necropsy Clinical examination is carried out at least once per week throughout the life of the flock in order to verify that the birds are free from fowl-pox virus and signs of any other infection. In the event of mortality exceeding 0.2 per cent per week, necropsy is performed on all available carcasses to verify that there is no sign of infection. Where appropriate, histopathological and/or microbiological/virological studies are performed to confirm diagnosis. Specific examination for tuberculosis lesions is carried out and histological samples from any suspected lesions are specifically stained to verify freedom from *Mycobacterium avium*. Caecal contents of all available carcasses are examined microbiologically for the presence of *Salmonella* spp. using the techniques described below. Where appropriate, caecal samples from up to 5 birds may be pooled.

Cultural testing for Salmonella spp Cultural testing for *Salmonella* spp. is performed either by testing samples of droppings or cloacal swabs or by testing of drag swabs. Where droppings or cloacal swabs are tested, a total of 60 samples within each 4-week period is tested throughout the entire life of the flock. Tests may be performed on pools of up to 10 samples. Where drag swabs are tested, a minimum of 2 drag swabs are tested during each 4-week period throughout the entire life of the flock. Detection of *Salmonella* spp. in these samples is performed by pre-enrichment of the samples followed by culture using *Salmonella*-selective media.

Tests for avian leucosis antigen Prior to the commencement of laying, cloacal swabs or blood samples (using buffy coat cultivation) are tested for the presence of group-specific leucosis antigen. A total of 5 per cent (minimum 10, maximum 200) of the flock is sampled during each 4-week period. During lay, albumen samples from 5 per cent (minimum 10, maximum 200) of the eggs are tested in each 4-week period. Tests are performed by EIA for group-specific antigen using methods that are capable of detecting antigen from subgroups A, B and J.

Test for antibodies to other agents Tests for antibodies to all agents listed in Table 5.2.2.-1 are performed throughout the laying period of the flock. In each 4-week period, samples are taken from 5 per cent (minimum 10, maximum 200) of the flock. It is recommended that 1.25 per cent of the flock is sampled each week since some test methods for some agents must be conducted on a weekly basis. Table 5.2.2.-1 classifies the agents into those that spread rapidly through the flock and those that spread slowly or may not infect the entire flock. For those agents listed as slowly spreading, each sample is tested individually. For those agents listed as rapidly spreading, at least 20 per cent of the samples collected in each 4-week period are tested individually or, where serum neutralisation or ELISA tests are employed, all of the samples may be tested individually or by preparing pools of 5 samples, collected at the same time.

Suitable methods to be used for detection of the agents are shown in Table 5.2.2.-1. Subject to agreement by the competent authority, other test methods may be used provided they are shown to be at least as sensitive as those indicated and of appropriate specificity.

Table 5.2.2.-1

Agent	Test to be used**	Vertical transmission	Rapid/slow spread
Avian adenoviruses, group I	AGP, EIA	yes	slow
Avian encephalomyelitis virus	AGP, EIA	yes	rapid
Avian infectious bronchitis virus	HI, EIA	no	rapid
Avian infectious laryngotracheitis virus	VN, EIA	no	slow
Avian leucosis viruses	EIA for virus, VN, EIA for antibody	yes	slow
Avian nephritis virus	IS	no	slow
Avian orthoreoviruses	IS, EIA	yes	slow
Avian reticuloendotheliosis virus	AGP, IS, EIA	yes	slow
Chicken anaemia virus	IS, EIA, VN	yes	slow
Egg drop syndrome virus	HI, EIA	yes	slow
Infectious bursal disease virus	Serotype 1: AGP, EIA, VN Serotype 2: VN	no	rapid
Influenza A virus	AGP, EIA, HI	no	rapid
Marek's disease virus	AGP	no	rapid
Newcastle disease virus	HI, EIA	no	rapid
Turkey rhinotracheitis virus	EIA	no	slow
Mycoplasma gallisepticum	Agg and HI to confirm a positive test, EIA, HI	yes	slow
Mycoplasma synoviae	Agg and HI to confirm a positive test, EIA, HI	yes	rapid
Salmonella pullorum	Agg	yes	slow

Agg: agglutination
AGP: agar gel precipitation; the technique is suitable where testing is carried out weekly
EIA: enzyme immunoassay
HI: haemagglutination inhibition
IS: immunostaining
VN: virus neutralisation

**Subject to agreement by the competent authority, other types of test may be used provided they are at least as sensitive as those indicated and of appropriate specificity.

Table 5.2.2-2. – *Schematic description of the establishment and maintenance of SPF flocks*

NEW STOCK	Establish freedom from vertically-transmissible agents
	Test all birds for avian leucosis antigen and antibodies prior to 20 weeks of age
	Test for *Salmonella* spp. and perform general clinical observation from 8 weeks of age
	Carry out routine testing for specified agents from 20 weeks of age
2nd GENERATION	Test all birds for avian leucosis antigen and antibodies prior to 20 weeks of age
	Test for *Salmonella* spp. and perform general clinical observation from 8 weeks of age
	Carry out routine testing for specified agents from 20 weeks of age
3rd GENERATION	Test all birds for avian leucosis antigen and antibodies prior to 20 weeks of age
	Test for *Salmonella* spp. and perform general clinical observation from 8 weeks of age
	DESIGNATE FLOCK AS SPF IF ALL TESTS ARE SATISFACTORY
3rd GENERATION	Carry out routine testing for specified agents from 20 weeks of age
	Carry out post-lay testing for vertically-transmissible agents
SUBSEQUENT GENERATIONS	Test two 5 per cent samples for avian leucosis antigen and for antibodies against specified agents between 12 and 20 weeks of age
	Test for *Salmonella* spp. and perform general clinical observation from 8 weeks of age
	Carry out routine testing for specified agents from 20 weeks of age
	Carry out post-lay testing for vertically-transmissible agents

TESTS TO BE CONDUCTED AT THE END OF THE LAYING PERIOD

Following the last egg collection, final testing to confirm the absence of vertically-transmissible agents indicated in Table 5.2.2.-1 is performed. After the last egg collection, a minimum of 5 per cent of the flock (minimum 10, maximum 200) is retained for at least 4 weeks. Blood samples are collected from every bird in the group during the 4-week period with at least 1.25 per cent of the birds (25 per cent of the sample) being bled not earlier than 4 weeks after the final egg collection. Serum samples are tested for vertically-transmissible agents (as defined by Table 5.2.2.-1) using the

methods indicated. Where sampling is performed on a weekly basis, at least 1.25 per cent of the birds (25 per cent of the sample) are tested each week during this period. Alternatively, within 4 weeks of the final egg collection blood and/or other suitable sample materials are collected from at least 5 per cent of the flock and tested for the presence of vertically-transmissible agents using validated nucleic acid amplification techniques (*2.6.21*).

ACTION TO BE TAKEN IN THE EVENT OF DETECTION OF A SPECIFIED AGENT

If evidence is found of contamination of the flock by an agent listed as slowly spreading in Table 5.2.2.-1, all materials derived from the flock during the 4-week period immediately preceding the date on which the positive sample was collected are considered unsatisfactory. Similarly, if evidence is found of contamination of the flock by an agent listed as rapidly spreading in Table 5.2.2.-1, all materials derived from the flock during the 2-week period immediately preceding the date on which the positive sample was collected are considered unsatisfactory. Any product manufactured with such materials, and for which the use of SPF materials is required, is considered unsatisfactory and must be discarded; any quality control tests conducted using the materials are invalid.

Producers must notify users of all eggs of the evidence of contamination as soon as possible following the outbreak.

Any flock in which an outbreak of any specified agent is confirmed may not be redesignated as an SPF flock. Any progeny derived from that flock during or after the 4-week period prior to the last negative sample being collected may not be designated as SPF.

J. Cell Substrates for the Production of Vaccines for Human Use

(Ph. Eur. general texts 5.2.3)

This general chapter deals with diploid cell lines and continuous cell lines used as cell substrates for the production of vaccines for human use; additional issues specifically related to vaccines prepared by recombinant DNA technology are covered by the monograph *Products of recombinant DNA technology (0784)*. The testing to be carried out at the various stages (cell seed, master cell bank (MCB), working cell bank (WCB), end of productions cells (EOPC) or extended cell bank (ECB) corresponding to cells at or beyond the maximum population doubling level used for production) is indicated in Table 5.2.3.-1. General provisions for the use of cell lines and test methods are given below. Where primary cells or cells that have undergone a few passages without constitution of a cell bank are used for vaccine production, requirements are given in the individual monograph for the vaccine concerned.

Diploid cell lines

A diploid cell line has a high but finite capacity for multiplication *in vitro*.

Continuous cell lines

A continuous cell line has the capacity to multiply indefinitely *in vitro*; the cells often have differences in karyotype compared to the original cells; they may be obtained from healthy or tumour tissue either from mammals or from insects.

There are perceived theoretical risks associated with the use of continuous cell lines, especially if their tumorigenic potential has been demonstrated experimentally. These risks are linked to the potential biological activity of the residual host-cell DNA present in the vaccine. The residual host-cell DNA may be associated with an infectivity risk if the genome of a DNA virus or a provirus is present in the cellular DNA (either integrated or extra chromosomal). In addition, there is a potential risk of oncogenicity if the cell substrate is tumorigenic.

For vaccines produced in continuous cell lines, whether tumorigenic or not, risk assessment and risk mitigation must be performed to evaluate the suitability of the cell substrate, to define the acceptable criteria for residual host-cell DNA in the final product and to evaluate the consistency of host-cell proteins.

Cell-bank system

Production of vaccines in diploid or continuous cell lines is based on a cell-bank system. The *in vitro* age of the cells is counted from the MCB. Each WCB is prepared from one or more containers of the MCB. The use, identity and inventory control of the containers is carefully documented.

Media and substances of human or animal origin

The composition of media used for isolation and all subsequent culture is recorded in detail, and if substances of human or animal origin are used they must be free from extraneous agents (*2.6.16*) and must comply with general chapter *5.1.7. Viral safety.*

If human albumin is used, it complies with the monograph *Human albumin solution (0255)*.

If bovine serum is used, it complies with the monograph *Bovine serum (2262)*.

Unless of recombinant origin, trypsin used for the preparation of cell cultures is tested by suitable methods and shown to be sterile and free from mycoplasmas and viruses.

Cell seed

The data used to assess the suitability of the cell seed comprises information, where available, on source, history and characterisation.

Source of the cell seed For human cell lines, the following information concerning the donor is recorded: ethnic and geographical origin; age; sex; general physiological condition; tissue or organ used; results of any tests for pathogens.

For animal cell lines, the following information concerning the source of the cells is recorded: species; strain; breeding conditions; geographical origin; age; sex; general physiological condition; tissue or organ used; results of any tests for pathogens.

Cells of neural origin, such as neuroblastoma and P12 cell lines are not used for vaccine production since they may contain substances that concentrate agents of spongiform encephalopathies.

History of the cell seed The following information is recorded: the method used to isolate the cell seed; culture methods; any other procedures used to establish the MCB, notably any that might expose the cells to extraneous agents.

Full information may not be available on the media ingredients used in the past for cultivation of cells, for example on the source of substances of animal origin; where justified and authorised, cell banks already established using such media may be used for vaccine production.

Characterisation of the cell seed The following properties are investigated:

(1) the identity of the cells, using methods such as isoenzyme analysis, *in vitro* immunochemical assays, nucleic acid fingerprinting and nucleic acid amplification techniques (NAT);

(2) the growth characteristics of the cells and their morphological properties (optical and electron microscopy);

(3) for diploid cell lines, karyotype;

(4) for diploid cell lines, the *in vivo* life span in terms of population doubling level.

Cell substrate stability

Suitable viability of the cell line in the intended storage conditions must be demonstrated. For a given product to be prepared in the cell line, it is necessary to demonstrate that consistent production can be obtained with cells at passage and/or population doubling levels at the beginning and end of the intended period of use.

Infectious extraneous agents

For cell lines for vaccine production, the testing for infectious extraneous agents must be carried out based on a risk assessment. The origin of the cell substrate as well as the potential extraneous agents that may be inadvertently introduced during production processes or through the use of animal or plant derived raw materials must be taken into account in the choice of suitable permissive cells. One such strategy is given in Table 5.2.3.-1, but alternative strategies could focus on more extensive testing at the MCB or WCB level. In any case, any strategy must be justified and lead to the same level of safety as outlined in Table 5.2.3-1. New, sensitive molecular techniques with broad detection capabilities are available, including massive parallel sequencing (MPS) methods, degenerate polymerase chain reaction (PCR) for whole virus families or random-priming methods (associated or not with sequencing), hybridisation to oligonucleotide arrays and mass spectrometry. These methods may be used either as an alternative to *in vivo* or specific NAT tests or as a supplement/alternative to *in vitro* culture tests, in agreement with the competent authority. The capacity of the process to remove/inactivate specific viruses must take into account the origin and culture history of the cell line and adventitious viruses that are known to persistently infect the species of origin, for example, simian virus 40 in rhesus monkeys, Flock house virus in insect cells or viruses that may inadvertently be introduced during production processes or through the use of raw materials of animal or plant origin. For cell lines of insect origin, tests for specific viruses relevant to the species of origin of the insect cells and for arboviruses (arthropod-borne viruses) are carried out. The panel of viruses tested is chosen according to the current state of scientific knowledge. For cell lines shown to express endogenous retroviral particles (e.g. rodent cells), the test for reverse transcriptase is not needed because it is expected to be positive, and thus infectivity tests must be performed to determine whether these endogenous retroviral particles are infectious or not.

Cell lines that show the presence of infectious retroviruses are not acceptable for production of vaccines, unless otherwise justified and authorised.

Tumorigenicity

Tumorigenicity is defined as the potential of a given cell line to induce a tumour after injection of intact live cells into immunodeficient/immunosuppressed animals (usually rodents). The tumorigenicity test is carried out using cells at or beyond the maximum population doubling level that will be used for vaccine production.

The MRC-5, WI-38 and FRhL-2 cell lines are recognised as being non-tumorigenic and further testing is not necessary. Known tumorigenic cell lines (e.g. CHO) do not need to be documented further.

When a previously uncharacterised cell line is tumorigenic, an oncogenicity study must be performed using purified DNA from the cell line and/or cell line lysate to demonstrate the absence of oncogenic components. The results are used as part of the risk analysis performed to support the use of the cell line for vaccine production. The determination of the TPD_{50} (tumour-producing dose in 50 per cent of animals) and the capacity to form metastases are characteristic properties that must be determined as part of the risk analysis.

Despite the difficulty in demonstrating a perfect and conclusive correlation with a tumorigenic phenotype, additional *in vitro* characterisation tests may be performed to document other cell substrate properties, such as the ability to grow in soft agar gels, the ability to induce invasive cell growth in muscle and/or the ability of the cell substrate to induce transformation of 3T3 cells.

Residual host-cell DNA

For each particular vaccine produced on continuous cell lines, residual host-cell DNA content must be tested and an acceptable upper limit, based on a risk assessment, must be established in the final product taking into consideration:

(1) the nature of the cell substrate (non-tumorigenic, level of tumorigenicity) and its origin (human/non-human);

(2) the presence in the production process of any steps to inactivate the potential biological activity (oncogenicity, infectivity) of the residual host-cell DNA (e.g. chemical agents such as betapropiolactone and/or DNase treatment);

(3) the capacity of the process to reduce the amount and size of the contaminating residual host-cell DNA;

(4) the intended use of the vaccine (e.g. route of administration);

(5) the method used to measure the residual host-cell DNA.

In general, a purification process for parenteral vaccines is able to reduce residual host-cell DNA in final products to less than 10 ng per dose, but the acceptance limits must be approved by the competent authority.

Once validation studies (e.g. spiking studies using an adequate size distribution of DNA) have been performed and the reproducibility of the production process in reducing residual host-cell DNA to the level expected has been demonstrated, residual host-cell DNA testing may be omitted after agreement from the competent authority.

Chromosomal characterisation

Diploid cell lines shall be shown to be diploid. More extensive characterisation of a diploid cell line by karyotype analysis is required if the removal of intact cells during post-harvest processing has not been validated. Samples from 4 passage levels evenly spaced over the life span of the cell line are examined. A minimum of 200 cells in metaphase are examined for exact chromosome count and for the frequency of hyperploidy, hypoploidy, polyploidy, breaks and structural abnormalities.

The MRC-5, WI-38 and FRhL-2 cell lines are recognised as being diploid and well characterised; where they are not genetically modified, further characterisation is not necessary.

Table 5.2.3.-1. – *Testing of cell lines*

Test	Cell seed	Master cell bank (MCB)	Working cell bank (WCB)	EOPC/ECB (Cells at or beyond the maximum population doubling level used for production)
	1. IDENTITY AND PURITY			
Morphology	+	+	+	+
Identification	+	+	+	+
Karyotype (diploid cell lines)	+	+	+(1)	+(1)
Life span (diploid cell lines)	–	+	+	–
	2. EXTRANEOUS AGENTS			
Bacterial and fungal contamination	–	+	+	–
Mycobacteria	–	+(2)	+(2)	–
Mycoplasmas	–	+	+	–
Spiroplasmas(3)	–	+	+	–
Electron microscopy	–	+(4)	–	+(4)
Tests for extraneous agents in cell cultures (with viable cells or equivalent cell lysate)	–	+	+	+
Tests in suckling mice and eggs	–	–	+(5)	+(5)
Test for specific viruses by NAT	–	+(6)	+(6)	+(6)
Test for viruses using broad molecular methods	+(7)	+(7)	+(7)	+(7)
Retroviruses	–	+(4)	–	+(4)
	3. TUMORIGENICITY			
Tumorigenicity	+(8, 9)	–	–	+(8)

(1) The diploid character is established for each WCB but using cells at or beyond the maximum population doubling level used for production.

(2) If the cells are susceptible to infection with *Mycobacterium tuberculosis* or other species.

(3) If insect cells or raw materials of plant origin are used.

(4) Testing is carried out for the MCB, but using cells at or beyond the maximum population doubling level used for production.

(5) Testing is carried out for each WCB, but using cells at or beyond the maximum population doubling level used for production.

(6) Specific tests for possible contaminants (e.g. viruses) defined according to a risk assessment based on the origin of the cells and on the potential extraneous agents inadvertently introduced during production processes or through the use of animal or plant derived raw materials. The appropriate testing stages should be selected based on the risk assessment.

(7) These methods may be used either as alternative to *in vivo* tests and specific NAT or as supplement or alternative to *in vitro* culture tests based on the risk assessment and in agreement with the competent authority. The appropriate testing stages should be selected based on the risk assessment.

(8) The MRC-5, WI-38 and FRhL-2 cell lines are recognised as being non-tumorigenic and they do not need to be tested. Tests are not carried out on cell lines that are known or assumed to be tumorigenic, for example CHO and BHK-21.

(9) Testing is carried out on the cell seed, but using cells at or beyond the maximum population doubling level used for production.

TEST METHODS FOR CELL CULTURES

Morphology

The morphology of the cells is adequately described and documented.

Identification

Nucleic acid fingerprint analysis and a relevant selection of the following are used to establish the identity of the cells:

(1) biochemical characteristics (isoenzyme analysis);

(2) immunological characteristics (histocompatibility antigens, *in vitro* immunochemical assays);

(3) cytogenetic markers;

(4) NAT.

Contaminating cells

The nucleic acid fingerprint analysis carried out for identification also serves to demonstrate freedom from contaminating cells.

Bacterial and fungal contamination

The MCB and each WCB comply with the test for sterility (*2.6.1*), carried out using, for each medium, 10 mL of supernatant from cell cultures. Carry out the test on 1 per cent of the containers, with a minimum of 2 containers.

Mycobacteria

If the cells are susceptible to infection with *Mycobacterium tuberculosis* or other species, the MCB and each WCB comply with the test for mycobacteria (*2.6.2*). NAT (*2.6.21*) may be used as an alternative to this culture method provided such an assay is validated and shown to be comparable to the culture method.

Mycoplasmas (*2.6.7*)

The MCB and each WCB comply with the test for mycoplasmas. Use one or more containers for the test.

Spiroplasmas

Spiroplasmas may be introduced into cell substrates through contamination of raw materials of plant origin or when insect cell lines are used. When appropriate, the MCB and each WCB are demonstrated to be free of spiroplasmas using a validated method approved by the competent authority. NAT methods for detection of mycoplasmas (*2.6.7*) may be used to detect spiroplasmas after validation and agreement from the competent authority. Use one or more containers for the test.

Electron microscopy

The MCB is examined by electron microscopy for the presence of extraneous agents. Cell lines are maintained at the temperature routinely used for production and taken at or beyond the maximum population doubling level used for production. In addition, insect cell lines are maintained at temperatures above and below those routinely used for production and may also be subjected to other treatments such as exposure to chemical stressors. For insect cell lines the maintenance temperatures and treatments used are agreed with the competent authority, along with the number of sectioned cells to be examined.

Test for extraneous agents in cell cultures

For mammalian cells, viable cells (at least 10^7 cells) or the equivalent cell lysate, in their culture supernatant, are either co-cultivated (for viable cells) or inoculated (for cell lysate) onto monolayer cultures of:

(1) human diploid cells;

(2) continuous simian kidney cells; and

(3) for cell substrates other than human or simian, cells of that species, from a separate batch.

For insect cell lines, cell lysates are inoculated onto monolayer cultures of other cell systems, including human, simian and, in addition, at least 1 cell line that is different from that used in production, is permissible to insect viruses and allows detection of human arboviruses (e.g. BHK-21).

The resulting co-cultivated cell culture (for viable cells) or inoculated cell cultures (for cell lysate) are observed for evidence of viruses by cytopathic effect for at least 2 weeks. If the cell line is known to be capable of supporting the growth of human or simian cytomegalovirus, the human diploid cultures are observed for at least 4 weeks.

The extended 4-week cell culture of human diploid cells, for the purpose of detecting human or simian cytomegalovirus, can be replaced by the use of NAT (*2.6.21*). In cases where it is difficult to keep the cell cultures healthy for the additional 2 weeks, it may be necessary to introduce fresh medium or to subculture after 2 weeks onto fresh cultures in order to be able to detect viral agents. At the end of the observation period, carry out tests on the cell culture supernatants for haemagglutinating viruses, or on the viable cells for haemadsorbing viruses using guinea-pig red blood cells. If the guinea-pig red blood cells have been stored, they shall have been stored at 5 ± 3 °C for not more than 7 days. Analyse half of the cultures after incubation at 5 ± 3 °C for 30 min and the other half after incubation at 20-25 °C for 30 min. The test for haemagglutinating viruses is not valid for arboviruses.

The test is not valid unless at least 80 per cent of the cell cultures remain viable. The cell substrate complies with the test if no evidence of any extraneous agent is found.

Retroviruses

If the cell line is not known to produce retroviral particles, examine for the presence of retroviruses using:

(1) product-enhanced reverse transcriptase (PERT) assay (*2.6.21*) carried out for cell bank supernatants using cells at or beyond the maximum population doubling level that will be used for production;

(2) transmission electron microscopy.

If tests (1) and/or (2) give a positive result, infectivity assays are carried out on permissible human cells with a PERT assay end-point on the supernatant.

If the cell line is shown to produce retroviral particles (e.g. rodent cell lines), examine for the presence of retroviruses using:

- transmission electron microscopy;
- infectivity assays carried out on permissible human cells and on relevant additional cells (e.g. *Mus dunni* cells or SC-1 cells for CHO cell substrate) with a PERT assay end-point on the supernatant, except when the amplification cells are positive for reverse transcriptase, in which case the readout is performed using plaque assay or a fluorescent focus assay.

Since the sensitivity of PERT assays is very high, interpretation of a positive signal may be equivocal and a decision on the acceptability of a cell substrate is based on all available data.

Tests in suckling mice

The test is carried out if a risk assessment indicates that it provides a risk mitigation taking into account the overall testing package applied to a given cell substrate.

Inject 10^7 viable cells or the equivalent cell lysate, in their culture supernatant into 2 litters of suckling mice less than 24 h old, comprising not fewer than 10 animals;

Inject at least 0.1 mL intraperitoneally and 0.01 mL intracerebrally.

Observe the suckling mice for at least 4 weeks. Investigate suckling mice that become sick or show any abnormality to establish the cause of illness. The cell substrate complies with the test if no evidence of any extraneous agent is found. The test is invalid if fewer than 80 per cent of the suckling mice in each group remain healthy and survive to the end of the observation period.

Tests in eggs (only required for avian cell substrates)

The test is carried out if a risk assessment indicates that it provides a risk mitigation taking into account the overall testing package applied to a given cell substrate. Inject an inoculum of 10^6 viable cells or the equivalent cell lysate, in their culture supernatant, into the allantoic cavity of ten 9- to 11-day-old SPF embryonated hens' eggs (*5.2.2*) and into the yolk sac of ten 5- to 7-day-old SPF embryonated hens' eggs. Incubate for not less than 5 days. Test the allantoic fluids for the presence of haemagglutinins using mammalian and avian red blood cells; carry out the test at 5 ± 3 °C and 20-25 °C and read the results after 30-60 min. The cell substrate complies with the test if no evidence of any extraneous agent is found. The test is invalid if fewer than 80 per cent of the embryos remain healthy and survive to the end of the observation period.

Tests for specific viruses

The list of specific viruses to be tested is defined based on a viral contamination risk assessment in accordance with the principles detailed in general chapter *5.1.7. Viral Safety*, and takes into account (but is not limited to) the origin of the cells and the potential sources of viral contamination (e.g. raw material of animal or plant origin). NAT tests (*2.6.21*) are carried out with or without prior amplification in cells. For cell lines of rodent origin, NAT (*2.6.21*) or antibody production tests in mice, rats or hamsters are used to detect species-specific viruses.

Tests for viruses using broad molecular methods

In agreement with the competent authority, broad molecular methods (e.g. High Throughput Sequencing) may be used either as an alternative to *in vivo* tests and specific NAT or as a supplement or alternative to *in vitro* culture tests based on the risk assessment.

For both NAT (*2.6.21*) and broad molecular methods, the stage at which testing is to be conducted (e.g. MCB, WCB, EOPC/ECB) is also based on the risk assessment and depends on the steps where viral contaminants may be introduced. In case of positive results with either broad molecular methods or NAT tests, a follow-up investigation must be conducted to determine whether detected nucleic acids are due to the presence of infectious extraneous agents and/or are known to constitute a risk to human health.

Tests for tumorigenicity *in vivo*

The test establishes a comparison between the continuous cell line and a suitable positive control cell line as reference (for example, HeLa or Hep2 cells).

Animal systems that have been shown to be suitable for this test include:

(1) athymic mice (Nu/Nu genotype);

(2) newborn mice, rats or hamsters that have been treated with antithymocyte serum or globulin;

(3) thymectomised and irradiated mice that have been reconstituted (T^-, B^+) with bone marrow from healthy mice.

Whichever animal system is selected, the cell line and the positive control cells are injected into separate groups of 10 animals each. In both cases, the inoculum for each animal is 10^7 cells suspended in a volume of 0.2 mL, and the injection may be given by the intramuscular or the subcutaneous route. Newborn animals are treated with 0.1 mL of antithymocyte serum or globulin on days 0, 2, 7 and 14 after birth. A potent serum or globulin is one that suppresses the immune mechanisms of growing animals to the extent that the subsequent inoculum of 10^7 positive control cells regularly produces tumours and metastases. Severely affected animals showing evident, progressively growing tumours are euthanised before the end of the test to avoid unnecessary suffering.

At the end of the observation period all animals, including the positive control group, are euthanised and examined for gross and microscopic evidence of the proliferation of inoculated cells at the site of injection and in other organs (for example, lymph nodes, lungs, kidneys and liver).

In all test systems, the animals are observed and palpated at regular intervals for the formation of nodules at the sites of injection. Any nodules formed are measured in 2 perpendicular directions, the measurements being recorded regularly to determine whether there is progressive growth of the nodule. Animals showing nodules that begin to regress during the period of observation are euthanised before the nodules are no longer palpable, and processed for histological examination. Animals with progressively growing nodules are observed for 1-2 weeks. Among those without nodule formation, half are observed for 3 weeks and half for 12 weeks before they are euthanised and processed for histological examination. A necropsy is performed on each animal and includes examination for gross evidence of tumour formation at the site of injection and in other organs such as lymph nodes, lungs, brain, spleen, kidneys and liver. All tumour-like lesions and the site of injection are examined histologically. In addition, since some cell lines may give rise to metastases without evidence of local tumour growth, any detectable regional lymph nodes and the lungs of all animals are examined histologically.

The test is invalid if fewer than 9 of the 10 animals injected with the reference positive-control cells show progressively growing tumours.

For a new tumorigenic cell line, in order to document the level of tumorigenicity, a dose range of cell substrate (e.g. dose of cells in the range of 10^5, 10^6 and 10^7) is injected in different groups of 10 animals. The number of animals showing progressively growing nodules within the animal groups is monitored to calculate the TPD_{50}.

K. Carrier Proteins for the Production of Conjugated Polysaccharide Vaccines for Human Use

(Ph. Eur. general text 5.2.11)

The use of alternative carrier proteins, production methods and tests are acceptable provided they have been authorised by the competent authority.

Bacterial polysaccharides are not able to induce a T-cell-dependent B-cell immune response, which is needed to obtain an immunological memory response, and are generally poorly immunogenic in children under 2 years of age. The limitations are overcome by conjugating polysaccharides to carrier proteins. Carrier proteins are highly immunogenic and, when conjugated to bacterial polysaccharides, increase the capacity of polysaccharides to induce a protective response in infants.

Carrier proteins currently used in polysaccharide vaccines for human use are toxoids, non-toxic mutated toxins, surface or outer membrane proteins extracted from micro-organisms. Micro-organisms used for the production of the protein may be of genetically modified origin.

The production method used for a carrier protein shall have been shown to yield consistently batches suitable for conjugation of the carrier protein to a polysaccharide antigen.

Appropriate acceptance criteria for low bioburden before conjugation with the polysaccharide may be established. It is a prerequisite that the carrier protein is filtered through a bacteria-retentive filter prior to storage and that adequate measures are in place to avoid contamination and growth of micro-organisms during storage.

The production of carrier proteins is based on a seed-lot system. The seed lots are shown to be free from contamination using suitable methods of appropriate sensitivity. The culture may be inactivated and the carrier protein is purified by a suitable method.

The protein is characterised by one or more suitable method(s) (such as SDS-PAGE, isoelectric focusing, HPLC, size-exclusion chromatography with multiple-angle laser light scattering detection (MALLS), amino-acid analysis, amino-acid sequencing, circular dichroism, fluorescence spectroscopy, peptide mapping and mass spectrometry) and its purity is verified by a suitable method. Suitable tests are carried out, for validation or routinely, to demonstrate that where applicable, the product is free from specific toxins. If purification steps are present, the reduction of selected process-related impurities and residuals is monitored to establish consistency of the purification process. In the case of recombinant carrier proteins, tests for at least the following impurities are also carried out:

— residual host-cell proteins, including proteins derived from the expression vector;
— residual cellular DNA.

Only a carrier protein that complies with the following tests may be used in the preparation of the conjugate.

Identification

The carrier protein is identified using a suitable method.

pH *(2.2.3)*

Where applicable, the pH of the carrier protein prior to conjugation is monitored and is within the limits approved for the particular product.

Protein content (*2.5.16*)
The content of the carrier protein is determined using a suitable method and is within the limits approved by the competent authority.

Bacterial endotoxins (*2.6.14*)
The content is within the limits approved for the particular product.

In addition, the following requirements apply for the carrier proteins listed below.

Diphtheria toxoid
It is produced as described in the monograph *Diphtheria vaccine (adsorbed) (0443)* and complies with the requirements prescribed therein for bulk purified toxoid, except that the test for sterility (*2.6.1*) is not required.

Tetanus toxoid
It is produced as described in the monograph *Tetanus vaccine (adsorbed) (0452)* and complies with the requirements prescribed therein for bulk purified toxoid, except that the antigenic purity is not less than 1500 Lf per milligram of protein nitrogen and that the test for sterility (*2.6.1*) is not required.

CRM 197 diphtheria protein
It may be prepared from the growth of genetically modified (C7/β197) or non-genetically modified (mCRM) *Corynebacterium diphtheriae* or prepared by recombinant DNA technology in organisms such as *Escherichia coli*. The culture supernatant may be concentrated by ultrafiltration and purified by successive precipitation, filtration, and chromatography steps. When it is produced on the same premises as diphtheria toxin, CRM 197 diphtheria protein should be distinguished from the active toxin by a suitable method. The purity is not less than 90 per cent of diphtheria protein.

OMP (*Neisseria meningitidis* group B outer membrane protein complex)
Neisseria meningitidis group B outer membrane protein complex is extracted from bacterial cell cultures with a buffer containing a detergent. Cell debris is first removed.
The membrane protein complex may be concentrated and purified by successive filtration and additional suitable purification steps. The lipopolysaccharide content does not exceed 8 per cent. The relative quantity of the major OMP is set and approved by the competent authority. The OMP complex complies with the test for pyrogens (*2.6.8*): inject into each rabbit 0.25 µg of OMP per kilogram of body mass.

Recombinant protein D
Protein D is a surface protein of nontypable *Haemophilus influenzae*. It is produced using a specific strain of *E. coli* carrying a plasmid containing the coding sequence for protein D. In order to express protein D, the modified strain is grown in a suitable liquid medium. At the end of cultivation, a purification step is carried out. The purity of the product is not less than 95 per cent of protein D.

L. Immunonephelometry for Vaccine Component Assay

(Ph. Eur. method 2.7.35)

GENERAL PRINCIPLE

The general principle of nephelometry is described in general chapter *2.2.1. Clarity and degree of opalescence of liquids.* Immunonephelometry measures turbidity that is mainly due to immune complexes formed by the antigen-antibody reaction. Although immunonephelometry is applicable for the quantification of both antibodies and antigens, this general chapter describes the quantification of antigens as vaccine components.

APPARATUS

The nephelometer used is described in general chapter *2.2.1. Clarity and degree of opalescence of liquids.* However the measurement may be made at a non-zero angle different from 90°.

METHODS

In general, the progress of the reaction measured by light scattering can be described in 3 steps.

Initially, a baseline level of light scattering due to the reaction medium is detected. After the 1st reagent (antigen) is added, an increase in the signal is observed followed by a plateau. When the 2nd reagent (antibody) is added, a 2nd increase of the signal is observed with a 2nd plateau followed by a final increase in the intensity of the signal, which continues until a 3rd plateau is reached. The measurement zone starts from the addition of the 2nd reagent until the higher intensity of light scattering (the 3rd plateau) is reached depending on the concentrations of the component to be assayed.

The following methods can be used to quantify the immune complexes formed during this type of reaction.

END-POINT NEPHELOMETRY
The light scattering is measured after the immune complex has formed, i.e. after about 60 min. The value of the end-point is in this case directly proportional to the content of the component to be assayed when an excess of antibodies is used. A blank is necessary in order to subtract the value of nonspecific scattering due to the reaction mixture and to the reaction/measurement cell.

RATE NEPHELOMETRY
Rate nephelometry is based on the rate of immune complex formation (rate of increase in light scattering), which is proportional to the concentration of the component to be assayed.

There are 2 types of rate nephelometry.

Fixed-time rate nephelometry
A 1st measurement of light scattering is carried out a few seconds after the last reagent has been added. A 2nd measurement is carried out after a fixed time interval established during development of the method.
The difference between the 2 values is proportional to the quantity of the component to be assayed.

Rate nephelometry using the peak of the first derivative
The formation of the immune complex is described by the curve of the first derivative of the variation in light scattering with time ($d\Theta_D/dt$). Two successive peaks are observed due to the addition of the 1st and then the 2nd reagent.

The height of the 3rd peak of the first derivative is proportional to the quantity of component to be assayed in the reaction medium. Successive measurements are carried out a few seconds after the 2nd reagent has been added.

In this case, the light scattered by the reaction medium, the component and the reagent does not affect the initial value of the derived signal.

OPERATING CONDITIONS

REAGENTS AND REFERENCE STANDARDS
The reagents, diluents and samples to be examined must be clear and free from any suspended particles. To this end, a

preliminary filtration or centrifugation step may be considered.

The antisera or antibodies are selected based on their specificity, their precipitating capacity and their avidity for the antigen. Indeed, high avidity results in clearly detectable signals being generated rapidly, which thus improves the quality of the results.

In addition, it is important to define the range of antigen concentrations to be assayed with an excess of antibodies and to verify the absence of a zone effect in this range.

It is recommended to ensure that the profiles of response will be similar to that of an appropriate reference standard.

PRE-TREATMENT OF THE SAMPLES TO BE EXAMINED

An appropriate pre-treatment could be envisaged to eliminate an adjuvant or another interfering substance.

ASSAY

Ensure that all the reagents are at a suitable temperature to optimise the reaction.

To the samples diluted with a suitable medium in the reaction measurement cell, add a fixed quantity of antibodies. Carry out several determinations of the dilution being examined.

In some cases, the progress of the reaction may be improved by introducing additional substances into the reaction medium (e.g. polyethylene glycol).

The reference standards and samples must be treated in the same manner.

PERFORMANCE OF A BLANK TEST

To ensure that the assays are specific, only the scattering due to immune complexes must be measured. Other particles, the matrix of the sample, the reagents or the reaction measurement cell may interfere. In this case and if the end-point method is used, it is necessary to carry out a blank test to avoid taking non-specific scattering into account.

CALIBRATION

The calibration curve is obtained by preparing a set of dilutions of a reference standard. The concentrations are chosen in order to encompass the working range.

METHODS OF CALCULATION

The parallel line method (see general chapter *5.3*) or a calibration curve is used for the calculations.

VALIDITY OF THE TESTS

VALIDITY OF THE CALIBRATION CURVES

Only calibration curves that comply with the defined validity criteria may be used.

The following parameters are examples to be used to define validity criteria:

- minimum of light scattering units (LSU) obtained for the lowest concentration point of the calibration curve;
- coefficient of variation for the LSU measured for each point on the curve;
- coefficients of regression or of correlation of the calibration curve;
- slope and intercept of the calibration curve.

VALIDITY OF THE RESULTS

The following criteria are examples of validity criteria of the samples to be assayed:

- coefficient of variation or the range of values for the determinations carried out on the sample;
- assay of an in-house reference standard with trend monitoring or a control chart.

M. Substitution of in Vivo Method(s) by in Vitro Method(s) for the Quality Control of Vaccines

(Ph. Eur. general texts 5.2.14)

PURPOSE

The purpose of this general chapter is to provide guidance to facilitate the implementation of *in vitro* methods as substitutes for existing *in vivo* methods, in cases where a typical one-to-one assay comparison is not appropriate for reasons unrelated to the suitability of one or more *in vitro* methods. This general chapter will not discuss the details of assay validation as such, since those principles are described elsewhere.

The general chapter applies primarily to vaccines for human or veterinary use, however the principles described may also apply to other biologicals such as sera.

CONTEXT

The test methods used for routine quality control of vaccines are intended to monitor production consistency and to ensure comparability of the quality attributes between commercial batches and those batches originally found to be safe and efficacious in clinical studies or, for veterinary vaccines, in the target species.

While the *in vivo* potency and safety assays described within Ph. Eur. vaccine monographs have historically played a central role in safeguarding the quality of vaccines, the inherent variability of *in vivo* assays can make them less suitable than appropriately designed *in vitro* assays for monitoring consistency of production and for assessing the potential impact of manufacturing changes. As a result, it is essential continually to challenge the scientific value and relevance of these *in vivo* test methods. When *in vivo* tests are found to be of limited or no value, it is imperative to eliminate them, given the ethical considerations and the obligations under the relevant conventions. In addition, there is a substantial effort to develop *in vitro* methods (including immunological, molecular and physico-chemical tests) to replace the animal tests. In several cases this has led to the successful introduction of new *in vitro* methods in vaccine monographs. The use of appropriate *in vitro* methods not only reduces the use of animals while maintaining or improving the scientific relevance of the assays involved, but also substantially reduces assay variability and the time and resources required, and enhances the predictability of the release of safe and effective vaccine lots for use.

In addition to the benefits resulting from the substitution of appropriate *in vitro* methods for existing *in vivo* methods, under the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes, the Ph. Eur. Commission has committed to the reduction of animal usage wherever possible in pharmacopoeial testing. Under the convention, those associated with the work of the European Pharmacopoeia are encouraged to develop and/or implement *in vitro* procedures, and the General Notices support the introduction of alternatives to *in vivo* methods described in Ph. Eur. monographs.

GENERAL CONSIDERATIONS

One of the consequences associated with the inherent variability of *in vivo* assays is the problem this poses with their replacement by the more-consistent *in vitro* methods, which typically requires one-to-one assay comparison. This

can be a challenge in some cases as repeated efforts through multicentre international collaborative studies can fail due to the variability inherent in the *in vivo* methods. Another consideration is that many of the legacy *in vivo* safety and potency assays for vaccines were generally shown to be fit for purpose and have historically proven their value in ensuring the efficacy and safety of vaccines. However, this was in an era when validation requirements, such as ICH Q2 (R1) or VICH GL2 guideline, were not in place, making a formal one-to-one comparison challenging or even impossible in some cases. Since precision, reproducibility, limits of detection and quantification were not established for the *in vivo* method, the comparability of one method to another becomes difficult to evaluate. It should also be noted that, because Ph. Eur. methods are considered validated under the General Notices, it is not only impractical and excessively costly now to undertake a retrospective ICH/VICH validation of these methods, but it would also be unethical given the above-mentioned convention on animal use in pharmacopoeial testing.

When considering the transition from an *in vivo*-based to an *in vitro*-based quality control assay system, it is important to understand what *in vivo* assays can and cannot offer. Although properly established *in vivo* potency assays in laboratory animals have the potential to measure complex functional responses for demonstrating proof of concept, these do not necessarily predict the actual responses in the target population. In addition, *in vitro* bioassays have the potential to mimic specific elements of complex *in vivo* responses with generally lower variability and higher sensitivity.

Another key consideration is that when an *in vivo* test for a given product is to be replaced with an *in vitro* test, the quality attribute(s) of the product will likely be assessed differently. Examples include: the determination of antigen content or a functional response (e.g. virus or toxin neutralisation) in an *in vitro* bioassay instead of *in vivo* potency; molecular consistency instead of *in vivo* neurovirulence or attenuated phenotype; absence of the extraneous agent genomes using molecular methods instead of absence of micro-organisms through *in vivo* testing; and demonstration of toxin binding and enzyme activity instead of *in vivo* specific toxicity. As a consequence, a demonstration of agreement between the 2 methods is generally not scientifically justified and should not always be expected. Even where pass/fail results from the 2 test procedures are in agreement, the correlation between 2 quantitative methods across the assay range may still be low. Regardless, the *in vitro* method(s) or testing strategy must provide at least the same confidence that the key quality attributes, which are necessary to ensure the consistency of a product's safety and effectiveness, are adequately controlled.

While the focus of this general chapter is on the replacement of existing methods for approved products, it is important to consider the use of *in vitro* methods for quality control during product development and to understand that the use of *in vivo* assays is not mandatory.

ALTERNATIVE APPROACHES FOR THE SUBSTITUTION OF *IN VIVO* METHODS

The primary focus for the implementation of any proposed *in vitro* methods within a quality control system should be the scientific relevance of *in vitro* assays for control of the relevant quality attributes. Additionally, any *in vitro* methods will have to meet the current validation requirements.

In the Ph. Eur., *in vivo* assays for vaccines are typically replaced by *in vitro* assays following multicentre collaborative studies, but this should not be a prerequisite for *in vivo* assay replacement initiatives for individual products. Additionally, while it may be desirable to have assays that are widely applicable to a class of products, this should not be a requirement.

As explained in the guidance below, in some cases an existing method may need to be substituted by more than 1 *in vitro* test, in order to characterise the key qualitative and quantitative attributes measured by the existing test.

POTENCY TESTS

When it is not possible to show agreement between the *in vitro* and *in vivo* methods due to low discriminating power and/or high variability of the *in vivo* assay, the following approach can be used. It is assumed that the product under consideration has a well-established safety and efficacy profile, with consistent manufacturing.

The *in vitro* test(s) should be able to detect differences that are relevant to the control of the production process as justified scientifically. This should be supported by data demonstrating the capability of the proposed assay(s) to control key quality attributes of the vaccine and maintain the link between the quality of the batches to be released and those batches found to be safe and efficacious through clinical studies or routine use. With the setting of appropriate specifications, the consistency of manufacturing with the *in vitro* method(s) will be maintained.

The design of an assay/assay system for vaccine quality control needs to reflect both antigen content and functionality. If a single method is used, it should preferably measure the content and integrity of the antigen by targeting epitope(s) relevant to the protection offered by the vaccine. An example of this would be a monoclonal antibody or monoclonal antibodies against an epitope or epitopes as the main target for generating neutralising antibodies.
The epitope or epitopes should preferably be conformational in order to have a stability-indicating assay (as is the case for rabies vaccine). In some cases, a single *in vitro* method may not adequately reflect the content and functionality. This can be remedied through the use of multiple assays, as is the case with conjugate polysaccharide vaccines, where molecular size, conjugate integrity, and total and free polysaccharides are examples of relevant measures.

To establish quantitative measurements with an *in vitro* method, samples that differ in the magnitude of the response will be needed. In most cases, samples that are below the minimum approved potency specification with the *in vivo* method will not be available because production consistency is generally well maintained, and potency between batches does not differ significantly and/or the precision of the *in vivo* assay is such that it cannot discriminate between batches unless the difference is very large. Therefore, initial assay evaluation should be performed with samples at different concentrations, which could be followed by testing of samples subjected to different types of stress conditions to assess further the stability-indicating potential of the new method. The inability to demonstrate agreement between an *in vitro* and an *in vivo* method does not necessarily mean that the *in vitro* method is not suitable/relevant. In many cases, an *in vitro* method will detect changes in the product profile that would not be detected by the *in vivo* method. In such cases, the *in vitro* method may be considered superior for monitoring the consistency of production and may be more relevant to assess the impact of manufacturing changes.

SAFETY TESTS

Specific toxicity

An *in vitro* method for detection of residual toxic components should be specific and at least as sensitive as the existing *in vivo* method. Where possible, a fully functional *in vitro* system should be used (e.g. toxin-sensitive cell line). Where no functional *in vitro* system is available, an *in vitro* testing strategy could be based on the detection/measurement of more than 1 parameter, sequentially where relevant, that together reflect the mode of action for the toxic components in question. Examples include the use of assays with immunological and biochemical steps to detect receptor binding and enzyme activity. In most cases, where an *in vivo* assay is to be replaced there will be data available on the sensitivity of that model for detection of the toxin in question. Therefore, new *in vitro* methods can be characterised to demonstrate that they are sufficiently sensitive using spiking experiments and referring to historic data for the *in vivo* assay. Such assays, in conjunction with the appropriate time and temperature conditions, could also be used to demonstrate the absence of reversion of a specific toxoid.

Molecular consistency by deep sequencing versus the neurovirulence test

An *in vitro* genotypic method to assess the molecular consistency of a viral vaccine has the potential to replace an existing *in vivo* neurovirulence test. A prerequisite for any *in vitro* genotypic method is an in-depth knowledge of the molecular markers responsible for the attenuation of the live viral vaccine (as is the case for oral poliovirus vaccine, for example). In such a case, monitoring the consistency of the vaccine lots would be achieved by confirming the presence of the required molecular attenuation markers and percentage of mutants with methods such as deep sequencing.

Detection of viral extraneous agents by novel molecular methods

Detection of viral extraneous agents in cell banks, seed lots and cell culture harvests is currently conducted using a panel of *in vivo* and *in vitro* methods at different stages of the manufacturing process. Novel, sensitive molecular techniques with broad detection capabilities are available, including deep sequencing or high-throughput sequencing methods, degenerate polymerase chain reaction (PCR) for whole virus families or random-priming methods (associated or not with sequencing), hybridisation to oligonucleotide arrays and mass spectrometry. The use of these new molecular methods has highlighted gaps in the existing testing strategy by identifying previously undetected viral contaminants in final product, the cell banks from which it was produced and intermediate manufacturing stages. These new molecular methods (e.g. deep sequencing or high-throughput sequencing) detect genomes while the existing *in vivo* methods are based on observations of the effects viruses have on experimental animals. The implementation of such new molecular methods as substitutes for *in vivo* methods requires a comparison of the specificity (breadth of detection) and the sensitivity of the new and existing methods. For this purpose, an appropriate panel of representative, well-characterised model viruses should be used to assess the ability of the new method to detect viruses that are (or are not) detected by the *in vivo* methods, and to determine if the sensitivity is at least equivalent to the sensitivity of the *in vivo* methods. This last element is particularly complex since these new molecular methods do not detect the same characteristic of the viral contaminant (genome for molecular methods versus infectious virus for *in vivo* methods) and also since no or limited validation data exist for the *in vivo* methods.
It should also be emphasised that the outcome of the new molecular methods is not the final result since the detection of a genome or fragments of a genome does not necessarily indicate the presence of an infectious virus.

Appendix XVI

A. Test for Sterility

Sterility[1]

(Ph. Eur. method 2.6.1)

The test is applied to substances, preparations or articles which, according to the Pharmacopoeia, are required to be sterile. However, a satisfactory result only indicates that no contaminating micro-organism has been found in the sample examined in the conditions of the test.

PRECAUTIONS AGAINST MICROBIAL CONTAMINATION

The test for sterility is carried out under aseptic conditions. In order to achieve such conditions, the test environment has to be adapted to the way in which the sterility test is performed. The precautions taken to avoid contamination are such that they do not affect any micro-organisms which are to be revealed in the test. The working conditions in which the tests are performed are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls.

CULTURE MEDIA AND INCUBATION TEMPERATURES

Media for the test may be prepared as described below, or equivalent commercial media may be used provided that they comply with the growth promotion test.

The following culture media have been found to be suitable for the test for sterility. Fluid thioglycollate medium is primarily intended for the culture of anaerobic bacteria; however, it will also detect aerobic bacteria. Soya-bean casein digest medium is suitable for the culture of both fungi and aerobic bacteria.

Fluid thioglycollate medium

L-Cystine	0.5 g
Agar	0.75 g
Sodium chloride	2.5 g
Glucose monohydrate/Glucose	5.5 g/5.0 g
Yeast extract (water-soluble)	5.0 g
Pancreatic digest of casein	15.0 g
Sodium thioglycollate or	0.5 g
Thioglycollic acid	0.3 mL
Resazurin sodium solution (1 g/L of resazurin sodium), freshly prepared	1.0 mL
Water R	1000 mL
pH after sterilisation 7.1 ± 0.2	

Mix the L-cystine, agar, sodium chloride, glucose, water-soluble yeast extract and pancreatic digest of casein with the *water R* and heat until solution is effected. Dissolve the sodium thioglycollate or thioglycollic acid in the solution and, if necessary, add *1 M sodium hydroxide* so that, after sterilisation, the solution will have a pH of 7.1 ± 0.2. If filtration is necessary, heat the solution again without boiling and filter while hot through moistened filter paper. Add the resazurin sodium solution, mix and place the medium in suitable vessels which provide a ratio of surface to depth of medium such that not more than the upper half of the medium has undergone a colour change indicative of oxygen uptake at the end of the incubation period. Sterilise using a validated process. If the medium is stored, store at a temperature between 2 °C and 25 °C in a sterile, airtight container. If more than the upper one-third of the medium has acquired a pink colour, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink colour disappears and cooling quickly, taking care to prevent the introduction of non-sterile air into the container. Do not use the medium for a longer storage period than has been validated.

Fluid thioglycollate medium is to be incubated at 30-35 °C.

For products containing a mercurial preservative that cannot be tested by the membrane-filtration method, fluid thioglycollate medium incubated at 20-25 °C may be used instead of soya-bean casein digest medium provided that it has been validated as described in growth promotion test.

Where prescribed or justified and authorised, the following alternative thioglycollate medium may be used. Prepare a mixture having the same composition as that of the fluid thioglycollate medium, but omitting the agar and the resazurin sodium solution, sterilise as directed above. The pH after sterilisation is 7.1 ± 0.2. Heat in a water-bath prior to use and incubate at 30-35 °C under anaerobic conditions.

Soya-bean casein digest medium

Pancreatic digest of casein	17.0 g
Papaic digest of soya-bean meal	3.0 g
Sodium chloride	5.0 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate/Glucose	2.5 g/2.3 g
Water R	1000 mL
pH after sterilisation 7.3 ± 0.2	

Dissolve the solids in *water R*, warming slightly to effect solution. Cool the solution to room temperature. Add *1 M sodium hydroxide*, if necessary, so that after sterilisation the solution will have a pH of 7.3 ± 0.2. Filter, if necessary, to clarify, distribute into suitable vessels and sterilise using a validated process. Store at a temperature between 2 °C and 25 °C in a sterile well-closed container, unless it is intended for immediate use. Do not use the medium for a longer storage period than has been validated.

Soya-bean casein digest medium is to be incubated at 20-25 °C.

The media used comply with the following tests, carried out before or in parallel with the test on the product to be examined.

Sterility

Incubate portions of the media for 14 days. No growth of micro-organisms occurs.

Growth promotion test of aerobes, anaerobes and fungi

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients. Suitable strains of micro-organisms are indicated in Table 2.6.1.-1.

Inoculate portions of fluid thioglycollate medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Clostridium sporogenes, Pseudomonas aeruginosa, Staphylococcus aureus.* Inoculate portions of soya-bean casein digest medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Aspergillus brasiliensis, Bacillus subtilis, Candida albicans.* Incubate for not more than 3 days in the case of bacteria and not more than 5 days in the case of fungi.

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

Table 2.6.1.-1. – *Strains of the test micro-organisms suitable for use in the growth promotion test and the method suitability test*

Aerobic bacteria	
Staphylococcus aureus	ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518, NBRC 13276
Bacillus subtilis	ATCC 6633, CIP 52.62, NCIMB 8054, NBRC 3134
Pseudomonas aeruginosa	ATCC 9027, NCIMB 8626, CIP 82.118, NBRC 13275
Anaerobic bacterium	
Clostridium sporogenes	ATCC 19404, CIP 79.3, NCTC 532, ATCC 11437, NBRC 14293
Fungi	
Candida albicans	ATCC 10231, IP 48.72, NCPF 3179, NBRC 1594
Aspergillus brasiliensis	ATCC 16404, IP 1431.83, IMI 149007, NBRC 9455

Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

The media are suitable if a clearly visible growth of the micro-organisms occurs.

METHOD SUITABILITY TEST

Carry out a test as described below under Test for sterility of the product to be examined using exactly the same methods except for the following modifications.

Membrane filtration

After transferring the contents of the container or containers to be tested to the membrane add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the final portion of sterile diluent used to rinse the filter.

Direct inoculation

After transferring the content of the container or containers to be tested (for catgut and other surgical sutures for veterinary use: strands) to the culture medium add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the medium.

In both cases use the same micro-organisms as those described above under Growth promotion test of aerobes, anaerobes and fungi. Perform a growth promotion test as a positive control. Incubate all the containers containing medium for not more than 5 days.

If clearly visible growth of micro-organisms is obtained after the incubation, visually comparable to that in the control vessel without product, either the product possesses no antimicrobial activity under the conditions of the test or such activity has been satisfactorily eliminated. The test for sterility may then be carried out without further modification.

If clearly visible growth is not obtained in the presence of the product to be tested, visually comparable to that in the control vessels without product, the product possesses antimicrobial activity that has not been satisfactorily eliminated under the conditions of the test. Modify the conditions in order to eliminate the antimicrobial activity and repeat the method suitability test.

This method suitability test is performed:

a) when the test for sterility has to be carried out on a new product;

b) whenever there is a change in the experimental conditions of the test.

The method suitability test may be performed simultaneously with the test for sterility of the product to be examined.

TEST FOR STERILITY OF THE PRODUCT TO BE EXAMINED

The test may be carried out using the technique of membrane filtration or by direct inoculation of the culture media with the product to be examined. Appropriate negative controls are included. The technique of membrane filtration is used whenever the nature of the product permits, that is, for filterable aqueous preparations, for alcoholic or oily preparations and for preparations miscible with or soluble in aqueous or oily solvents provided these solvents do not have an antimicrobial effect in the conditions of the test.

Membrane filtration

Use membrane filters having a nominal pore size not greater than 0.45 µm whose effectiveness to retain micro-organisms has been established. Cellulose nitrate filters, for example, are used for aqueous, oily and weakly alcoholic solutions and cellulose acetate filters, for example, for strongly alcoholic solutions. Specially adapted filters may be needed for certain products, e.g. for antibiotics.

The technique described below assumes that membranes about 50 mm in diameter will be used. If filters of a different diameter are used the volumes of the dilutions and the washings should be adjusted accordingly. The filtration apparatus and membrane are sterilised by appropriate means. The apparatus is designed so that the solution to be examined can be introduced and filtered under aseptic conditions; it permits the aseptic removal of the membrane for transfer to the medium or it is suitable for carrying out the incubation after adding the medium to the apparatus itself.

Aqueous solutions If appropriate, transfer a small quantity of a suitable, sterile diluent such as a 1 g/L neutral solution of meat or casein peptone pH 7.1 ± 0.2 onto the membrane in the apparatus and filter. The diluent may contain suitable neutralising substances and/or appropriate inactivating substances for example in the case of antibiotics.

Transfer the contents of the container or containers to be tested to the membrane or membranes, if necessary after diluting to the volume used in the method suitability test with the chosen sterile diluent but in any case using not less than the quantities of the product to be examined prescribed in Table 2.6.1.-2. Filter immediately. If the product has antimicrobial properties, wash the membrane not less than 3 times by filtering through it each time the volume of the chosen sterile diluent used in the method suitability test. Do not exceed a washing cycle of 5 times 100 mL per filter, even if during the method suitability test it has been demonstrated that such a cycle does not fully eliminate the antimicrobial activity. Transfer the whole membrane to the culture medium or cut it aseptically into 2 equal parts and

Table 2.6.1.-2. – *Minimum quantity to be used for each medium*

Quantity per container	Minimum quantity to be used for each medium unless otherwise justified and authorised
Liquids	
— less than 1 mL	The whole contents of each container
— 1-40 mL	Half the contents of each container but not less than 1 mL
— greater than 40 mL and not greater than 100 mL	20 mL
— greater than 100 mL	10 per cent of the contents of the container but not less than 20 mL
Antibiotic liquids	1 mL
Insoluble preparations, creams and ointments to be suspended or emulsified	Use the contents of each container to provide not less than 200 mg
Solids	
— less than 50 mg	The whole contents of each container
— 50 mg or more but less than 300 mg	Half the contents of each container but not less than 50 mg
— 300 mg to 5 g	150 mg
— greater than 5 g	500 mg
Catgut and other surgical sutures for veterinary use	3 sections of a strand (each 30 cm long)

transfer one half to each of 2 suitable media. Use the same volume of each medium as in the method suitability test. Alternatively, transfer the medium onto the membrane in the apparatus. Incubate the media for not less than 14 days.

Soluble solids Use for each medium not less than the quantity prescribed in Table 2.6.1.-2 of the product dissolved in a suitable solvent such as the solvent provided with the preparation, water for injections, saline or a 1 g/L neutral solution of meat or casein peptone and proceed with the test as described above for aqueous solutions using a membrane appropriate to the chosen solvent.

Oils and oily solutions Use for each medium not less than the quantity of the product prescribed in Table 2.6.1.-2. Oils and oily solutions of sufficiently low viscosity may be filtered without dilution through a dry membrane. Viscous oils may be diluted as necessary with a suitable sterile diluent such as isopropyl myristate shown not to have antimicrobial activity in the conditions of the test. Allow the oil to penetrate the membrane by its own weight then filter, applying the pressure or suction gradually. Wash the membrane at least 3 times by filtering through it each time about 100 mL of a suitable sterile solution such as 1 g/L neutral meat or casein peptone containing a suitable emulsifying agent at a concentration shown to be appropriate in the method suitability test, for example polysorbate 80 at a concentration of 10 g/L. Transfer the membrane or membranes to the culture medium or media or vice versa as described above for aqueous solutions, and incubate at the same temperatures and for the same times.

Ointments and creams Use for each medium not less than the quantities of the product prescribed in Table 2.6.1.-2. Ointments in a fatty base and emulsions of the water-in-oil type may be diluted to 1 per cent in isopropyl myristate as described above, by heating, if necessary, to not more than 40 °C. In exceptional cases it may be necessary to heat to not more than 44 °C. Filter as rapidly as possible and proceed as described above for oils and oily solutions.

Direct inoculation of the culture medium

Transfer the quantity of the preparation to be examined prescribed in Table 2.6.1.-2 directly into the culture medium so that the volume of the product is not more than 10 per cent of the volume of the medium, unless otherwise prescribed.

If the product to be examined has antimicrobial activity, carry out the test after neutralising this with a suitable neutralising substance or by dilution in a sufficient quantity of culture medium. When it is necessary to use a large volume of the product it may be preferable to use a concentrated culture medium prepared in such a way that it takes account of the subsequent dilution. Where appropriate, the concentrated medium may be added directly to the product in its container.

Oily liquids Use media to which have been added a suitable emulsifying agent at a concentration shown to be appropriate in the method suitability test, for example polysorbate 80 at a concentration of 10 g/L.

Ointments and creams Prepare by diluting to about 1 in 10 by emulsifying with the chosen emulsifying agent in a suitable sterile diluent such as a 1 g/L neutral solution of meat or casein peptone. Transfer the diluted product to a medium not containing an emulsifying agent.

Incubate the inoculated media for not less than 14 days. Observe the cultures several times during the incubation period. Shake cultures containing oily products gently each day. However when fluid thioglycollate medium is used for the detection of anaerobic micro-organisms keep shaking or mixing to a minimum in order to maintain anaerobic conditions.

Catgut and other surgical sutures for veterinary use

Use for each medium not less than the quantities of the product prescribed in Table 2.6.1.-2. Open the sealed package using aseptic precautions and remove 3 sections of the strand for each culture medium. Carry out the test on 3 sections, each 30 cm long, cut off from the beginning, the centre and the end of the strand. Use whole strands from freshly opened cassette packs. Transfer each section of the strand to the selected medium. Use sufficient medium to cover adequately the material to be tested (20 mL to 150 mL).

Table 2.6.1.-3. —*Minimum number of items to be tested*

Number of items in the batch*	Minimum number of items to be tested for each medium, unless otherwise justified and authorised**
Parenteral preparations	
— Not more than 100 containers	10 per cent or 4 containers, whichever is the greater
— More than 100 but not more than 500 containers	10 containers
— More than 500 containers	2 per cent or 20 containers (10 containers for large-volume parenterals) whichever is less
Ophthalmic and other non-injectable preparations	
— Not more than 200 containers	5 per cent or 2 containers, whichever is the greater
— More than 200 containers	10 containers
— If the product is presented in the form of single-dose containers, apply the scheme shown above for preparations for parenteral administration	
Catgut and other surgical sutures for veterinary use	2 per cent or 5 packages whichever is the greater, up to a maximum total of 20 packages
Bulk solid products	
— Up to 4 containers	Each container
— More than 4 containers but not more than 50 containers	20 per cent or 4 containers, whichever is the greater
— More than 50 containers	2 per cent or 10 containers, whichever is the greater

* If the batch size is not known, use the maximum number of items prescribed.
**If the contents of one container are enough to inoculate the 2 media, this column gives the number of containers needed for both the media together.

OBSERVATION AND INTERPRETATION OF RESULTS

At intervals during the incubation period and at its conclusion, examine the media for macroscopic evidence of microbial growth. If the material being tested renders the medium turbid so that the presence or absence of microbial growth cannot be readily determined by visual examination, 14 days after the beginning of incubation transfer portions (each not less than 1 mL) of the medium to fresh vessels of the same medium and then incubate the original and transfer vessels for not less than 4 days.

If no evidence of microbial growth is found, the product to be examined complies with the test for sterility. If evidence of microbial growth is found the product to be examined does not comply with the test for sterility, unless it can be clearly demonstrated that the test was invalid for causes unrelated to the product to be examined. The test may be considered invalid only if one or more of the following conditions are fulfilled:

a) the data of the microbiological monitoring of the sterility testing facility show a fault;

b) a review of the testing procedure used during the test in question reveals a fault;

c) microbial growth is found in the negative controls;

d) after determination of the identity of the micro-organisms isolated from the test, the growth of this species or these species may be ascribed unequivocally to faults with respect to the material and/or the technique used in conducting the sterility test procedure.

If the test is declared to be invalid it is repeated with the same number of units as in the original test.

If no evidence of microbial growth is found in the repeat test the product examined complies with the test for sterility.
If microbial growth is found in the repeat test the product examined does not comply with the test for sterility.

APPLICATION OF THE TEST TO PARENTERAL PREPARATIONS, OPHTHALMIC AND OTHER NON-INJECTABLE PREPARATIONS REQUIRED TO COMPLY WITH THE TEST FOR STERILITY

When using the technique of membrane filtration, use, whenever possible, the whole contents of the container, but not less than the quantities indicated in Table 2.6.1.-2, diluting where necessary to about 100 mL with a suitable sterile solution, such as 1 g/L neutral meat or casein peptone.

When using the technique of direct inoculation of media, use the quantities shown in Table 2.6.1.-2, unless otherwise justified and authorised. The tests for bacterial and fungal sterility are carried out on the same sample of the product to be examined. When the volume or the quantity in a single container is insufficient to carry out the tests, the contents of 2 or more containers are used to inoculate the different media.

MINIMUM NUMBER OF ITEMS TO BE TESTED

The minimum number of items to be tested in relation to the size of the batch is given in Table 2.6.1.-3.

Guidelines on the test for sterility are given in general chapter 5.1.9.

B. Microbiological Examination of Non-sterile Products

1. Test for Specified Micro-organisms[1]

(Ph. Eur. method 2.6.13)

1 INTRODUCTION

The tests described hereafter will allow determination of the absence or limited occurrence of specified micro-organisms that may be detected under the conditions described.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2 GENERAL PROCEDURES

The preparation of samples is carried out as described in general chapter *2.6.12.*

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralised as described in general chapter *2.6.12.*

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated as described in general chapter *2.6.12.*

3 GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA, SUITABILITY OF THE TEST AND NEGATIVE CONTROLS

The ability of the test to detect micro-organisms in the presence of the product to be tested must be established. Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

3-1 PREPARATION OF TEST STRAINS

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

3-1-1 Aerobic micro-organisms

Grow each of the bacterial test strains separately in casein soya bean digest broth or on casein soya bean digest agar at 30-35 °C for 18-24 h. Grow the test strain for *Candida albicans* separately on Sabouraud-dextrose agar or in Sabouraud-dextrose broth at 20-25 °C for 2-3 days.

- *Staphylococcus aureus* such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276;
- *Pseudomonas aeruginosa* such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275;
- *Escherichia coli* such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972;
- *Salmonella enterica* subsp. *enterica* serovar Typhimurium, such as ATCC 14028 or, as an alternative, *Salmonella enterica* subsp. *enterica* serovar Abony such as NBRC 100797, NCTC 6017 or CIP 80.39;
- *Candida albicans* such as ATCC 10231, NCPF 3179, IP 48.72 or NBRC 1594.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C.

3-1-2 Clostridia

Use *Clostridium sporogenes* such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.03). Grow the clostridial test strain under anaerobic conditions in reinforced medium for clostridia at 30-35 °C for 24-48 h. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of *C. sporogenes*, a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period.

3-2 NEGATIVE CONTROL

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described in section 4. A failed negative control requires an investigation.

3-3 GROWTH PROMOTION AND INHIBITORY PROPERTIES OF THE MEDIA

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients.

Verify suitable properties of relevant media as described in Table 2.6.13.-1.

Test for growth promoting properties, liquid media

Inoculate a portion of the appropriate medium with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Clearly visible growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Test for growth promoting properties, solid media

Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Test for inhibitory properties, liquid or solid media

Inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test micro-organism occurs.

Test for indicative properties Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

3-4 SUITABILITY OF THE TEST METHOD

For each product to be tested, perform the sample preparation as described in the relevant paragraph in section 4. Add each test strain at the time of mixing, in the prescribed growth medium. Inoculate the test strains

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

Table 2.6.13.-1 – *Growth promoting, inhibitory and indicative properties of media*

	Medium	Property	Test strains
Test for bile-tolerant gram-negative bacteria	Enterobacteria enrichment broth-Mossel	Growth promoting	*E. coli* *P. aeruginosa*
		Inhibitory	*S. aureus*
	Violet red bile glucose agar	Growth promoting + indicative	*E. coli* *P. aeruginosa*
Test for *Escherichia coli*	MacConkey broth	Growth promoting	*E. coli*
		Inhibitory	*S. aureus*
	MacConkey agar	Growth promoting + indicative	*E. coli*
Test for *Salmonella*	Rappaport Vassiliadis *Salmonella* enrichment broth	Growth promoting	*Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony
		Inhibitory	*S. aureus*
	Xylose, lysine, deoxycholate agar	Growth promoting + indicative	*Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony
Test for *Pseudomonas aeruginosa*	Cetrimide agar	Growth promoting	*P. aeruginosa*
		Inhibitory	*E. coli*
Test for *Staphylococcus aureus*	Mannitol salt agar	Growth promoting + indicative	*S. aureus*
		Inhibitory	*E. coli*
Test for clostridia	Reinforced medium for clostridia	Growth promoting	*C. sporogenes*
	Columbia agar	Growth promoting	*C. sporogenes*
Test for *Candida albicans*	Sabouraud dextrose broth	Growth promoting	*C. albicans*
	Sabouraud dextrose agar	Growth promoting + indicative	*C. albicans*

individually. Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation.

Perform the test as described in the relevant paragraph in section 4 using the shortest incubation period prescribed.

The specified micro-organisms must be detected with the indication reactions as described in section 4.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see 4-5-3 of general chapter *2.6.12*).

If for a given product the antimicrobial activity with respect to a micro-organism for which testing is prescribed cannot be neutralised, then it is to be assumed that the inhibited micro-organism will not be present in the product.

4 TESTING OF PRODUCTS

4-1 BILE-TOLERANT GRAM-NEGATIVE BACTERIA

4-1-1 Sample preparation and pre-incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, but using casein soya bean digest broth as the chosen diluent, mix and incubate at 20-25 °C for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 h but not more than 5 h).

4-1-2 Test for absence

Unless otherwise prescribed, use the volume corresponding to 1 g of the product, as prepared in 4-1-1, to inoculate enterobacteria enrichment broth-Mossel. Incubate at 30-35 °C for 24-48 h. Subculture on plates of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

The product complies with the test if there is no growth of colonies.

4-1-3 Quantitative test

4-1-3-1 Selection and subculture. Inoculate suitable quantities of enterobacteria enrichment broth-Mossel with the preparation as described under 4-1-1 and/or dilutions of it containing respectively 0.1 g, 0.01 g and 0.001 g (or 0.1 mL, 0.01 mL and 0.001 mL) of the product to be examined. Incubate at 30-35 °C for 24-48 h. Subculture each of the cultures on a plate of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

4-1-3-2 Interpretation. Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result. Determine from Table 2.6.13.-2 the probable number of bacteria.

Table 2.6.13.-2 – *Interpretation of results*

Results for each quantity of product			Probable number of bacteria per gram or millilitre of product
0.1 g or 0.1 mL	0.01 g or 0.01 mL	0.001 g or 0.001 mL	
+	+	+	$> 10^3$
+	+	–	$< 10^3$ and $> 10^2$
+	–	–	$< 10^2$ and > 10
–	–	–	< 10

4-2 ESCHERICHIA COLI

4-2-1 Sample preparation and pre-incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

◊When testing orodispersible films, filter the volume of sample corresponding to 1 film of the preparation described under 4-5-1 in general chapter *2.6.12* through a sterile filter membrane and place in 100 mL of casein soya bean digest broth. Incubate at 30-35 °C for 18-24 h.◊

4-2-2 Selection and subculture

Shake the container, transfer 1 mL of casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on a plate of MacConkey agar at 30-35 °C for 18-72 h.

4-2-3 Interpretation

Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The product complies with the test if no colonies are present or if the identification tests are negative.

4-3 SALMONELLA

4-3-1 Sample preparation and pre-incubation

Prepare the product to be examined as described in general chapter *2.6.12*, and use the quantity corresponding to not less than 10 g or 10 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

4-3-2 Selection and subculture

Transfer 0.1 mL of casein soya bean digest broth to 10 mL of Rappaport Vassiliadis *Salmonella* enrichment broth and incubate at 30-35 °C for 18-24 h. Subculture on plates of xylose, lysine, deoxycholate agar. Incubate at 30-35 °C for 18-48 h.

4-3-3 Interpretation

The possible presence of *Salmonella* is indicated by the growth of well-developed, red colonies, with or without black centres. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-4 PSEUDOMONAS AERUGINOSA

4-4-1 Sample preparation and pre-incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. When testing transdermal patches ◊or orodispersible films◊, filter the volume of sample corresponding to 1 patch ◊or 1 film◊ of the preparation described under 4-5-1 in general chapter *2.6.12* through a sterile filter membrane and place in 100 mL of casein soya bean digest broth. Incubate at 30-35 °C for 18-24 h.

4-4-2 Selection and subculture

Subculture on a plate of cetrimide agar and incubate at 30-35 °C for 18-72 h.

4-4-3 Interpretation

Growth of colonies indicates the possible presence of *P. aeruginosa*. This is confirmed by identification tests.

The product complies with the test if colonies are not present or if the confirmatory identification tests are negative.

4-5 STAPHYLOCOCCUS AUREUS

4-5-1 Sample preparation and pre-incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. When testing transdermal patches ◊or orodispersible films◊, filter the volume of sample corresponding to 1 patch ◊or 1 film◊ of the preparation described under 4-5-1 in general chapter *2.6.12* through a sterile filter membrane and place in 100 mL of casein soya bean digest broth. Incubate at 30-35 °C for 18-24 h.

4-5-2 Selection and subculture

Subculture on a plate of mannitol salt agar and incubate at 30-35 °C for 18-72 h.

4-5-3 Interpretation

The possible presence of *S. aureus* is indicated by the growth of yellow/white colonies surrounded by a yellow zone. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-6 CLOSTRIDIA

4-6-1 Sample preparation and heat treatment

Prepare a sample using a 1 in 10 dilution (with a minimum total volume of 20 mL) of not less than 2 g or 2 mL of the product to be examined as described in general chapter *2.6.12*. Divide the sample into 2 portions of at least 10 mL. Heat 1 portion at 80 °C for 10 min and cool rapidly. Do not heat the other portion.

4-6-2 Selection and subculture

Use 10 mL or the quantity corresponding to 1 g or 1 mL of the product to be examined of both portions to inoculate suitable amounts (determined as described under 3-4) of reinforced medium for clostridia. Incubate under anaerobic conditions at 30-35 °C for 48 h. After incubation, make subcultures from each container on Columbia agar and incubate under anaerobic conditions at 30-35 °C for 48-72 h.

4-6-3 Interpretation

The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction indicates the presence of clostridia. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-7 CANDIDA ALBICANS

4-7-1 Sample preparation and pre-incubation

Prepare the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to not less than 1 g or 1 mL to inoculate 100 mL of Sabouraud-dextrose broth and mix. Incubate at 30-35 °C for 3-5 days.

4-7-2 Selection and subculture

Subculture on a plate of Sabouraud-dextrose agar and incubate at 30-35 °C for 24-48 h.

4-7-3 Interpretation

Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.

The product complies with the test if such colonies are not present or if the confirmatory identification tests are negative.

The following section is given for information.

5 RECOMMENDED SOLUTIONS AND CULTURE MEDIA

The following solutions and culture media have been found to be satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopoeia. Other media may be used provided that their suitability can be demonstrated.

Stock buffer solution Place 34 g of potassium dihydrogen phosphate in a 1000 mL volumetric flask, dissolve in 500 mL of purified water, adjust to pH 7.2 ± 0.2 with sodium hydroxide, dilute to 1000.0 mL with purified water and mix. Dispense into containers and sterilise. Store at 2-8 °C.

Phosphate buffer solution pH 7.2 Prepare a mixture of stock buffer solution and purified water (1:800 *V/V*) and sterilise.

Buffered sodium chloride-peptone solution pH 7.0

Potassium dihydrogen phosphate	3.6 g
Disodium hydrogen phosphate dihydrate	7.2 g, equivalent to 0.067 M phosphate
Sodium chloride	4.3 g
Peptone (meat or casein)	1.0 g
Purified water	1000 mL

Sterilise in an autoclave using a validated cycle.

Casein soya bean digest broth

Pancreatic digest of casein	17.0 g
Papaic digest of soya bean	3.0 g
Sodium chloride	5.0 g
Dipotassium hydrogen phosphate	2.5 g
Glucose monohydrate	2.5 g
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Casein soya bean digest agar

Pancreatic digest of casein	15.0 g
Papaic digest of soya bean	5.0 g
Sodium chloride	5.0 g
Agar	15.0 g
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Sabouraud-dextrose agar

Dextrose	40.0 g
Mixture of peptic digest of animal tissue and pancreatic digest of casein (1:1)	10.0 g
Agar	15.0 g
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Potato dextrose agar

Infusion from potatoes	200 g
Dextrose	20.0 g
Agar	15.0 g
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Sabouraud-dextrose broth

Dextrose	20.0 g
Mixture of peptic digest of animal tissue and pancreatic digest of casein (1:1)	10.0 g
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Enterobacteria enrichment broth-Mossel

Pancreatic digest of gelatin	10.0 g
Glucose monohydrate	5.0 g
Dehydrated ox bile	20.0 g
Potassium dihydrogen phosphate	2.0 g
Disodium hydrogen phosphate dihydrate	8.0 g
Brilliant green	15 mg
Purified water	1000 mL

Adjust the pH so that after heating it is 7.2 ± 0.2 at 25 °C. Heat at 100 °C for 30 min and cool immediately.

Violet red bile glucose agar

Yeast extract	3.0 g
Pancreatic digest of gelatin	7.0 g
Bile salts	1.5 g
Sodium chloride	5.0 g
Glucose monohydrate	10.0 g
Agar	15.0 g
Neutral red	30 mg
Crystal violet	2 mg
Purified water	1000 mL

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25 °C. Heat to boiling; do not heat in an autoclave.

MacConkey broth

Pancreatic digest of gelatin	20.0 g
Lactose monohydrate	10.0 g
Dehydrated ox bile	5.0 g
Bromocresol purple	10 mg
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

MacConkey agar

Pancreatic digest of gelatin	17.0 g
Peptones (meat and casein)	3.0 g
Lactose monohydrate	10.0 g
Sodium chloride	5.0 g
Bile salts	1.5 g
Agar	13.5 g
Neutral red	30.0 mg
Crystal violet	1 mg
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 7.1 ± 0.2 at 25 °C. Boil for 1 min with constant shaking then sterilise in an autoclave using a validated cycle.

Rappaport Vassiliadis *Salmonella* enrichment broth

Soya peptone	4.5 g
Magnesium chloride hexahydrate	29.0 g
Sodium chloride	8.0 g
Dipotassium phosphate	0.4 g
Potassium dihydrogen phosphate	0.6 g
Malachite green	0.036 g
Purified water	1000 mL

Dissolve, warming gently. Sterilise in an autoclave using a validated cycle, at a temperature not exceeding 115 °C. The pH is to be 5.2 ± 0.2 at 25 °C after heating and autoclaving.

Xylose, lysine, deoxycholate agar

Xylose	3.5 g
L-Lysine	5.0 g
Lactose monohydrate	7.5 g
Sucrose	7.5 g
Sodium chloride	5.0 g
Yeast extract	3.0 g
Phenol red	80 mg
Agar	13.5 g
Sodium deoxycholate	2.5 g
Sodium thiosulfate	6.8 g
Ferric ammonium citrate	0.8 g
Purified water	1000 mL

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25 °C. Heat to boiling, cool to 50 °C and pour into Petri dishes. Do not heat in an autoclave.

Cetrimide agar

Pancreatic digest of gelatin	20.0 g
Magnesium chloride	1.4 g
Dipotassium sulfate	10.0 g
Cetrimide	0.3 g
Agar	13.6 g
Purified water	1000 mL
Glycerol	10.0 mL

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.2 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Mannitol salt agar

Pancreatic digest of casein	5.0 g
Peptic digest of animal tissue	5.0 g
Beef extract	1.0 g
D-Mannitol	10.0 g
Sodium chloride	75.0 g
Agar	15.0 g
Phenol red	0.025 g
Purified water	1000 mL

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.4 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Reinforced medium for clostridia

Beef extract	10.0 g
Peptone	10.0 g
Yeast extract	3.0 g
Soluble starch	1.0 g
Glucose monohydrate	5.0 g
Cysteine hydrochloride	0.5 g
Sodium chloride	5.0 g
Sodium acetate	3.0 g
Agar	0.5 g
Purified water	1000 mL

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 6.8 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

Columbia agar

Pancreatic digest of casein	10.0 g
Meat peptic digest	5.0 g
Heart pancreatic digest	3.0 g
Yeast extract	5.0 g
Maize starch	1.0 g
Sodium chloride	5.0 g
Agar, according to gelling power	10.0-15.0 g
Purified water	1000 mL

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle. Allow to cool to 45-50 °C; add, where necessary, gentamicin sulfate corresponding to 20 mg of gentamicin base and pour into Petri dishes.

2. Microbial Enumeration Tests[2]

(Ph. Eur. method 2.6.12)

1 INTRODUCTION

The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi that may grow under aerobic conditions.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

The methods are not applicable to products containing viable micro-organisms as active ingredients.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2 GENERAL PROCEDURES

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the product to be examined. The precautions taken to avoid contamination must be such that they do not affect any micro-organisms that are to be revealed in the test.

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralised. If inactivators are used for this purpose, their efficacy and their absence of toxicity for micro-organisms must be demonstrated.

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated.

3 ENUMERATION METHODS

Use the membrane filtration method or the plate-count methods, as prescribed. The most-probable-number (MPN) method is generally the least accurate method for microbial counts, however, for certain product groups with a very low bioburden, it may be the most appropriate method.

The choice of method is based on factors such as the nature of the product and the required limit of micro-organisms. The chosen method must allow testing of a sufficient sample size to judge compliance with the specification.
The suitability of the method chosen must be established.

4 GROWTH PROMOTION TEST, SUITABILITY OF THE COUNTING METHOD AND NEGATIVE CONTROLS

4-1 GENERAL CONSIDERATIONS

The ability of the test to detect micro-organisms in the presence of product to be tested must be established.

Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

4-2 PREPARATION OF TEST STRAINS

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance

[2] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

Table 2.6.12.-1. – *Preparation and use of test micro-organisms*

Micro-organism	Preparation of test strain	Growth promotion		Suitability of counting method in the presence of the product	
		Total aerobic microbial count	Total yeasts and moulds count	Total aerobic microbial count	Total yeasts and moulds count
Staphylococcus aureus such as: ATCC 6538 NCIMB 9518 CIP 4.83 NBRC 13276	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Pseudomonas aeruginosa such as: ATCC 9027 NCIMB 8626 CIP 82.118 NBRC 13275	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Bacillus subtilis such as: ATCC 6633 NCIMB 8054 CIP 52.62 NBRC 3134	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Candida albicans such as: ATCC 10231 NCPF 3179 IP 48.72 NBRC 1594	Sabouraud-dextrose agar or Sabouraud-dextrose broth 20-25 °C 2-3 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days
Aspergillus brasiliensis such as: ATCC 16404 IMI 149007 IP 1431.83 NBRC 9455	Sabouraud-dextrose agar or potato-dextrose agar 20-25 °C 5-7 days, or until good sporulation is achieved	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable	Sabouraud-dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days

techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in Table 2.6.12.-1.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions; to suspend *A. brasiliensis* spores, 0.05 per cent of polysorbate 80 may be added to the buffer. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *A. brasiliensis* or *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period of time.

4-3 NEGATIVE CONTROL

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described in section 5. A failed negative control requires an investigation.

4-4 GROWTH PROMOTION OF THE MEDIA

Test each batch of ready-prepared medium and each batch of medium, prepared either from dehydrated medium or from the ingredients described.

Inoculate portions/plates of casein soya bean digest broth and casein soya bean digest agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.12.-1, using a separate portion/plate of medium for each. Inoculate plates of Sabouraud-dextrose agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.12.-1, using a separate plate of medium for each. Incubate in the conditions described in Table 2.6.12.-1.

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardised inoculum. For a freshly prepared inoculum, growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs. Liquid media are suitable if clearly visible growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

4-5 SUITABILITY OF THE COUNTING METHOD IN THE PRESENCE OF PRODUCT

4-5-1 Preparation of the sample

The method for sample preparation depends upon the physical characteristics of the product to be tested. If none of the procedures described below can be demonstrated to be satisfactory, an alternative procedure must be developed.

Water-soluble products Dissolve or dilute (usually a 1 in 10 dilution is prepared) the product to be examined in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

Non-fatty products insoluble in water Suspend the product to be examined (usually a 1 in 10 dilution is prepared) in buffered sodium chloride-peptone solution

pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. A surface-active agent such as 1 g/L of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

Fatty products Dissolve in isopropyl myristate, sterilised by filtration or mix the product to be examined with the minimum necessary quantity of sterile polysorbate 80 or another non-inhibitory sterile surface-active agent, heated if necessary to not more than 40 °C, or in exceptional cases to not more than 45 °C. Mix carefully and if necessary maintain the temperature in a water-bath. Add sufficient of the pre-warmed chosen diluent to make a 1 in 10 dilution of the original product. Mix carefully whilst maintaining the temperature for the shortest time necessary for the formation of an emulsion. Further serial tenfold dilutions may be prepared using the chosen diluent containing a suitable concentration of sterile polysorbate 80 or another non-inhibitory sterile surface-active agent.

Fluids or solids in aerosol form Aseptically transfer the product into a membrane filter apparatus or a sterile container for further sampling. Use either the total contents or a defined number of metered doses from each of the containers tested.

Transdermal patches Remove the protective cover sheets ('release liners') of the transdermal patches and place them, adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with a sterile porous material, for example sterile gauze, to prevent the patches from sticking together, and transfer the patches to a suitable volume of the chosen diluent containing inactivators such as polysorbate 80 and/or lecithin. Shake the preparation vigorously for at least 30 min.

◊*Orodispersible films.* Dissolve 10 films to be examined in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. It may be necessary to heat the preparation to not more than 40 °C, or in exceptional cases to not more than 45 °C, with or without shaking, to achieve dissolution. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.◊

4-5-2 Inoculation and dilution

Add to the sample prepared as described above (4-5-1) and to a control (with no test material included) a sufficient volume of the microbial suspension to obtain an inoculum of not more than 100 CFU. The volume of the suspension of the inoculum should not exceed 1 per cent of the volume of diluted product.

To demonstrate acceptable microbial recovery from the product, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to antimicrobial activity or poor solubility, further appropriate protocols must be developed. If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the microbial suspension may be added after neutralisation, dilution or filtration.

4-5-3 Neutralisation/removal of antimicrobial activity

The number of micro-organisms recovered from the prepared sample diluted as described in 4-5-2 and incubated following the procedure described in 4-5-4, is compared to the number of micro-organisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), then modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example, (1) an increase in the volume of the diluent or culture medium, (2) incorporation of specific or general neutralising agents into the diluent, (3) membrane filtration, or (4) a combination of the above measures.

Neutralising agents Neutralising agents may be used to neutralise the activity of antimicrobial agents (Table 2.6.12.-2). They may be added to the chosen diluent or the medium preferably before sterilisation. If used, their efficacy and their absence of toxicity for micro-organisms must be demonstrated by carrying out a blank with neutraliser and without product.

If no suitable neutralising method can be found, it can be assumed that the failure to isolate the inoculated organism is attributable to the microbicidal activity of the product. This information serves to indicate that the product is not likely to be contaminated with the given species of the micro-organism. However, it is possible that the product only inhibits some of the micro-organisms specified herein, but does not inhibit others not included amongst the test strains or for which the latter are not representative. Then, perform the test with the highest dilution factor compatible with microbial growth and the specific acceptance criterion.

Table 2.6.12.-2. – *Common neutralising agents for interfering substances*

Interfering substance	Potential neutralising method
Glutaraldehyde, mercurials	Sodium hydrogensulfite (sodium bisulfite)
Phenolics, alcohol, aldehydes, sorbate	Dilution
Aldehydes	Glycine
Quaternary Ammonium Compounds (QACs), parahydroxybenzoates (parabens), bis-biguanides	Lecithin
QACs, iodine, parabens	Polysorbate
Mercurials	Thioglycollate
Mercurials, halogens, aldehydes	Thiosulfate
EDTA (edetate)	Mg^{2+} or Ca^{2+} ions

4-5-4 Recovery of micro-organism in the presence of product

For each of the micro-organisms listed, separate tests are performed. Only micro-organisms of the added test strain are counted.

4-5-4-1 Membrane filtration. Use membrane filters having a nominal pore size not greater than 0.45 µm. The type of filter material is chosen such that the bacteria-retaining efficiency is not affected by the components of the sample to be investigated. For each of the micro-organisms listed, one membrane filter is used.

Transfer a suitable amount of the sample prepared as described under 4-5-1 to 4-5-3 (preferably representing 1 g of the product, or less if large numbers of CFU are expected) to the membrane filter, filter immediately and rinse the membrane filter with an appropriate volume of diluent.

For the determination of total aerobic microbial count (TAMC), transfer the membrane filter to the surface of casein soya bean digest agar. For the determination of total combined yeasts/moulds count (TYMC), transfer the membrane to the surface of Sabouraud-dextrose agar.

Incubate the plates as indicated in Table 2.6.12.-1. Perform the counting.

4-5-4-2 Plate-count methods. Perform plate-count methods at least in duplicate for each medium and use the mean count of the result.

4-5-4-2-1 Pour-plate method

For Petri dishes 9 cm in diameter, add to the dish 1 mL of the sample prepared as described under 4-5-1 to 4-5-3 and 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar, both media being at not more than 45 °C. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the micro-organisms listed in Table 2.6.12.-1, at least 2 Petri dishes are used. Incubate the plates as indicated in Table 2.6.12.-1. Take the arithmetic mean of the counts per medium and calculate the number of CFU in the original inoculum.

4-5-4-2-2 Surface-spread method

For Petri dishes 9 cm in diameter, add 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar at about 45 °C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a laminar-air-flow cabinet or an incubator. For each of the micro-organisms listed in Table 2.6.12.-1, at least 2 Petri dishes are used. Spread a measured volume of not less than 0.1 mL of the sample prepared as described under 4-5-1 to 4-5-3 over the surface of the medium. Incubate and count as prescribed under 4-5-4-2-1

4-5-4-3 Most-probable-number (MPN) method.

The precision and accuracy of the MPN method is less than that of the membrane filtration method or the plate-count method. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of TAMC in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least 3 serial tenfold dilutions of the product as described under 4-5-1 to 4-5-3. From each level of dilution, 3 aliquots of 1 g or 1 mL are used to inoculate 3 tubes with 9-10 mL of casein soya bean digest broth. If necessary, a surface-active agent such as polysorbate 80 or an inactivator of antimicrobial agents may be added to the medium. Thus, if 3 levels of dilution are prepared, 9 tubes are inoculated.

Incubate all tubes at 30-35 °C for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth, or in casein soya bean digest agar, for 1-2 days at the same temperature and use these results. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 2.6.12.-3.

4-6 RESULTS AND INTERPRETATION

When verifying the suitability of the membrane filtration method or the plate-count method, a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in 4-5-2 in the absence of the product must be obtained. When verifying the suitability of the MPN method the calculated value from the inoculum must be within 95 per cent confidence limits of the results obtained with the control.

If the above criteria cannot be met for one or more of the organisms tested with any of the described methods, the method and test conditions that come closest to the criteria are used to test the product.

Table 2.6.12.-3. – *Most-probable-number values of micro-organisms*

Observed combinations of numbers of tubes showing growth in each set			MPN per gram or per millilitre of product	95 per cent confidence limits

5 TESTING OF PRODUCTS

5-1 AMOUNT USED FOR THE TEST

Unless otherwise prescribed, use 10 g or 10 mL of the product to be examined taken with the precautions referred to above. For fluids or solids in aerosol form, sample 10 containers. For transdermal patches, sample 10 patches. ◊For orodispersible films, sample 10 films.◊

The amount to be tested may be reduced for active substances that will be formulated in the following conditions: the amount per dosage unit (e.g. tablet, capsule, injection) is less than or equal to 1 mg or the amount per gram or millilitre (for preparations not presented in dose units) is less than 1 mg. In these cases, the amount to be tested is not less than the amount present in 10 dosage units or 10 g or 10 mL of the product.

For materials used as active substances where sample quantity is limited or batch size is extremely small (i.e. less than 1000 mL or 1000 g), the amount tested shall be 1 per cent of the batch unless a lesser amount is prescribed or justified and authorised.

For products where the total number of entities in a batch is less than 200 (e.g. samples used in clinical trials), the sample size may be reduced to 2 units, or 1 unit if the size is less than 100.

Select the sample(s) at random from the bulk material or from the available containers of the preparation. To obtain the required quantity, mix the contents of a sufficient number of containers to provide the sample.

5-2 EXAMINATION OF THE PRODUCT

5-2-1 Membrane filtration

Use a filtration apparatus designed to allow the transfer of the filter to the medium. Prepare the sample using a method that has been shown suitable as described in section 4 and transfer the appropriate amount to each of 2 membrane filters and filter immediately. Wash each filter following the procedure shown to be suitable.

For the determination of TAMC, transfer one of the membrane filters to the surface of casein soya bean digest agar. For the determination of TYMC, transfer the other membrane to the surface of Sabouraud-dextrose agar. Incubate the plate of casein soya bean digest agar at 30-35 °C for 3-5 days and the plate of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Calculate the number of CFU per gram or per millilitre of product.

When examining transdermal patches ◊or orodispersible films◊, filter 10 per cent of the volume of the preparation described under 4-5-1 separately through each of 2 sterile filter membranes. Transfer one membrane to casein soya bean digest agar for TAMC and the other membrane to Sabouraud-dextrose agar for TYMC.

5-2-2 Plate-count methods

5-2-2-1 Pour-plate method

Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare for each medium at least 2 Petri dishes for each level of dilution. Incubate the plates of casein soya bean digest agar at 30-35 °C for 3-5 days and the plates of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Select the plates corresponding to a given dilution and showing the highest number of colonies less than 250 for TAMC and 50 for TYMC. Take the arithmetic mean per culture medium of the counts and calculate the number of CFU per gram or per millilitre of product.

5-2-2-2 Surface-spread method

Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare at least 2 Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of CFU proceed as described for the pour-plate method.

5-2-3 Most-probable-number method

Prepare and dilute the sample using a method that has been shown to be suitable as described in section 4. Incubate all tubes at 30-35 °C for 3-5 days. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 2.6.12.-3.

5-3 INTERPRETATION OF THE RESULTS

The total aerobic microbial count (TAMC) is considered to be equal to the number of CFU found using casein soya bean digest agar; if colonies of fungi are detected on this medium, they are counted as part of the TAMC. The total combined yeasts/mould count (TYMC) is considered to be equal to the number of CFU found using Sabouraud-dextrose agar; if colonies of bacteria are detected on this medium, they are counted as part of the TYMC. When the TYMC is expected to exceed the acceptance criterion due to the bacterial growth, Sabouraud-dextrose agar containing antibiotics may be used. If the count is carried out by the MPN method the calculated value is the TAMC.

When an acceptance criterion for microbiological quality is prescribed it is interpreted as follows:

- 10^1 CFU: maximum acceptable count = 20;
- 10^2 CFU: maximum acceptable count = 200;
- 10^3 CFU: maximum acceptable count = 2000, and so forth.

The recommended solutions and media are described in general chapter *2.6.13.*

3. Test for Absence of Mycoplasmas

(Ph. Eur. method 2.6.7 as applied to vaccines for human use)

Where the test for mycoplasmas is prescribed for a master cell bank, for a working cell bank, for a virus seed lot or for control cells, both the culture method and the indicator cell culture method are used. Where the test for mycoplasmas is prescribed for a virus harvest, for a bulk vaccine or for the final lot (batch), the culture method is used. The indicator cell culture method may also be used, where necessary, for screening of media.

Nucleic acid amplification techniques (NAT) may be used as an alternative to one or both of the other methods after suitable validation.

CULTURE METHOD

CHOICE OF CULTURE MEDIA

The test is carried out using a sufficient number of both solid and liquid media to ensure growth in the chosen incubation conditions of small numbers of mycoplasmas that may be present in the product to be examined. Liquid media must contain phenol red. The range of media chosen is shown to have satisfactory nutritive properties for at least the micro-organisms shown below. The nutritive properties of each new batch of medium are verified for the appropriate micro-organisms in the list. When testing for mycoplasmas in the product to be examined, at least 1 of the following species will be included as a positive control:

- *Acholeplasma laidlawii* (vaccines for human and veterinary use where an antibiotic has been used during production);

— *Mycoplasma gallisepticum* (where avian material has been used during production or where the vaccine is intended for use in poultry);
— *Mycoplasma hyorhinis* (non-avian veterinary vaccines);
— *Mycoplasma orale* (vaccines for human and veterinary use);
— *Mycoplasma pneumoniae* (vaccines for human use) or other suitable species of D-glucose fermenter such as *Mycoplasma fermentans*;
— *Mycoplasma synoviae* (where avian material has been used during production or where the vaccine is intended for use in poultry).

The test strains are field isolates having undergone a limited number of subcultures (not more than 15), and are stored frozen or freeze-dried. After cloning, the strains are identified as being of the required species by comparison with type cultures, for example:

A. laidlawii	NCTC 10116	CIP 75.27	ATCC 23206
M. gallisepticum	NCTC 10115	CIP 104967	ATCC 19610
M. fermentans	NCTC 10117	CIP 105680	ATCC 19989
M. hyorhinis	NCTC 10130	CIP 104968	ATCC 17981
M. orale	NCTC 10112	CIP 104969	ATCC 23714
M. pneumoniae	NCTC 10119	CIP 103766	ATCC 15531
M. synoviae	NCTC 10124	CIP 104970	ATCC 25204

Acholeplasma laidlawii BRP, Mycoplasma fermentans BRP, Mycoplasma hyorhinis BRP, Mycoplasma orale BRP and *Mycoplasma synoviae BRP* are suitable for use as low-passage reference strains.

INCUBATION CONDITIONS

Incubate liquid media in tightly stoppered containers at 35-38 °C. Incubate solid media in microaerophilic conditions (nitrogen containing 5-10 per cent of carbon dioxide and sufficient humidity to prevent desiccation of the agar surface) at 35-38 °C.

NUTRITIVE PROPERTIES

Carry out the test for nutritive properties for each new batch of medium Inoculate the chosen media with the appropriate test micro-organisms; use not more than 100 CFU per 60 mm diameter plate containing 9 mL of solid medium and per 100 mL container of liquid medium; use a separate plate and container for each species of micro-organism. Incubate the media and make subcultures from 0.2 mL of liquid medium to solid medium at the specified intervals (see below under Test for mycoplasmas in the product to be examined). The solid medium complies with the test if adequate growth is found for each test micro-organism (growth obtained does not differ by a factor greater than 5 from the value calculated with respect to the inoculum). The liquid medium complies with the test if growth on agar plates subcultured from the broth is found for at least 1 subculture for each test micro-organism.

INHIBITORY SUBSTANCES

The test for inhibitory substances is carried out once for a given product and is repeated whenever there is a change in production method that may affect the detection of mycoplasmas.

To demonstrate absence of inhibitory substances, carry out the test for nutritive properties in the presence and absence of the product to be examined. If growth of a test micro-organism occurs more than 1 subculture sooner in the absence of the product to be examined than in its presence, or if plates directly inoculated with the product to be examined have fewer than 1/5 of the number of colonies of those inoculated without the product to be examined, inhibitory substances are present and they must be neutralised or their effect otherwise countered, for example by passage in substrates not containing inhibitors or dilution in a larger volume of medium before the test. If dilution is used, larger medium volumes may be used or the inoculum volume may be divided among several 100 mL flasks. The effectiveness of the neutralisation or other process is checked by repeating the test for inhibitory substances after neutralisation.

TEST FOR MYCOPLASMAS IN THE PRODUCT TO BE EXAMINED

Inoculate 10 mL of the product to be examined per 100 mL of each liquid medium. If it has been found that a significant pH change occurs upon the addition of the product to be examined, the liquid medium is restored to its original pH value by the addition of a solution of either sodium hydroxide or hydrochloric acid. Inoculate 0.2 mL of the product to be examined on each plate of each solid medium. Incubate liquid media for 20-21 days. Incubate solid media for not less than 14 days, except those corresponding to the 20-21 day subculture, which are incubated for 7 days. At the same time incubate an uninoculated 100 mL portion of each liquid medium and agar plates, as a negative control. On days 2-4 after inoculation, subculture each liquid medium by inoculating 0.2 mL on at least 1 plate of each solid medium. Repeat the procedure between the 6th and 8th days, again between the 13th and 15th days and again between the 19th and 21st days of the test. Observe the liquid media every 2 or 3 days and if a colour change occurs, subculture. If a liquid medium shows bacterial or fungal contamination, the test is invalid. The test is valid if at least 1 plate per medium and per inoculation day can be read. Include in the test positive controls prepared by inoculation of not more than 100 CFU of at least 1 test micro-organism on agar medium or into broth medium. Where the test for mycoplasmas is carried out regularly and where possible, it is recommended to use the test micro-organisms in regular rotation. The test micro-organisms used are those listed under Choice of culture media.

INTERPRETATION OF RESULTS

At the end of the prescribed incubation period, examine all inoculated solid media microscopically for the presence of mycoplasma colonies. The product complies with the test if growth of typical mycoplasma colonies has not occurred. The product does not comply with the test if growth of typical mycoplasma colonies has occurred on any of the solid media. The test is invalid if 1 or more of the positive controls do not show growth of mycoplasmas on at least 1 subculture plate. The test is invalid if 1 or more of the negative controls show growth of mycoplasmas. If suspect colonies are observed, a suitable validated method may be used to determine whether they are due to mycoplasmas.

The following section is published for information.

RECOMMENDED MEDIA FOR THE CULTURE METHOD

The following media are recommended. Other media may be used, provided that their ability to sustain the growth of mycoplasmas has been demonstrated on each batch in the presence and absence of the product to be examined.

HAYFLICK MEDIA (RECOMMENDED FOR THE GENERAL DETECTION OF MYCOPLASMAS)

Liquid medium

Beef heart infusion broth (1)	90.0 mL
Horse serum (unheated)	20.0 mL
Yeast extract (250 g/L)	10.0 mL
Phenol red (0.6 g/L solution)	5.0 mL
Penicillin (20 000 IU/mL)	0.25 mL
Deoxyribonucleic acid (2 g/L solution)	1.2 mL

Adjust to pH 7.8.

Solid medium

Prepare as described above replacing beef heart infusion broth by beef heart infusion agar containing 15 g/L of agar.

FREY MEDIA (RECOMMENDED FOR THE DETECTION OF M. SYNOVIAE)

Liquid medium

Beef heart infusion broth (1)	90.0 mL
Essential vitamins (2)	0.025 mL
Glucose monohydrate (500 g/L solution)	2.0 mL
Swine serum (inactivated at 56 °C for 30 min)	12.0 mL
β-Nicotinamide adenine dinucleotide (10 g/L solution)	1.0 mL
Cysteine hydrochloride (10 g/L solution)	1.0 mL
Phenol red (0.6 g/L solution)	5.0 mL
Penicillin (20 000 IU/mL)	0.25 mL

Mix the solutions of β-nicotinamide adenine dinucleotide and cysteine hydrochloride and after 10 min add to the other ingredients. Adjust to pH 7.8.

Solid medium

Beef heart infusion broth (1)	90.0 mL
Agar, purified (3)	1.4 g

Adjust to pH 7.8, sterilise by autoclaving then add:

Essential vitamins (2)	0.025 mL
Glucose monohydrate (500 g/L solution)	2.0 mL
Swine serum (unheated)	12.0 mL
β-Nicotinamide adenine dinucleotide (10 g/L solution)	1.0 mL
Cysteine hydrochloride (10 g/L solution)	1.0 mL
Phenol red (0.6 g/L solution)	5.0 mL
Penicillin (20 000 IU/mL)	0.25 mL

FRIIS MEDIA (RECOMMENDED FOR THE DETECTION OF NON-AVIAN MYCOPLASMAS)

Liquid medium

Hanks' balanced salt solution (modified) (4)	800 mL
Distilled water	67 mL
Brain heart infusion (5)	135 mL
PPLO Broth (6)	248 mL
Yeast extract (170 g/L)	60 mL
Bacitracin	250 mg
Meticillin	250 mg
Phenol red (5 g/L)	4.5 mL
Horse serum	165 mL
Swine serum	165 mL

Adjust to pH 7.40-7.45.

Solid medium

Hanks' balanced salt solution (modified) (4)	200 mL
DEAE-dextran	200 mg
Agar, purified (3)	15.65 g

Mix well and sterilise by autoclaving. Cool to 100 °C. Add to 1740 mL of liquid medium as described above.

(1) *Beef heart infusion broth*

Beef heart (for preparation of the infusion)	500 g
Peptone	10 g
Sodium chloride	5 g
Distilled water	to 1000 mL

Sterilise by autoclaving.

(2) *Essential vitamins*

Biotin	100 mg
Calcium pantothenate	100 mg
Choline chloride	100 mg
Folic acid	100 mg
i-Inositol	200 mg
Nicotinamide	100 mg
Pyridoxal hydrochloride	100 mg
Riboflavine	10 mg
Thiamine hydrochloride	100 mg
Distilled water	to 1000 mL

(3) *Agar, purified*

A highly refined agar for use in microbiology and immunology, prepared by an ion-exchange procedure that results in a product having superior purity, clarity and gel strength. It contains about:

Water	12.2 per cent
Ash	1.5 per cent
Acid-insoluble ash	0.2 per cent
Chlorine	0
Phosphate (calculated as P_2O_5)	0.3 per cent
Total nitrogen	0.3 per cent
Copper	8 ppm
Iron	170 ppm
Calcium	0.28 per cent
Magnesium	0.32 per cent

(4) *Hanks' balanced salt solution (modified)*

Sodium chloride	6.4 g
Potassium chloride	0.32 g
Magnesium sulfate heptahydrate	0.08 g
Magnesium chloride hexahydrate	0.08 g
Calcium chloride, anhydrous	0.112 g
Disodium hydrogen phosphate dihydrate	0.0596 g
Potassium dihydrogen phosphate, anhydrous	0.048 g
Distilled water	to 800 mL

(5) *Brain heart infusion*

Calf-brain infusion	200 g
Beef-heart infusion	250 g
Proteose peptone	10 g
Glucose monohydrate	2 g
Sodium chloride	5 g
Disodium hydrogen phosphate, anhydrous	2.5 g
Distilled water	to 1000 mL

(6) *PPLO broth*

Beef-heart infusion	50 g
Peptone	10 g
Sodium chloride	5 g
Distilled water	to 1000 mL

INDICATOR CELL CULTURE METHOD

Cell cultures are stained with a fluorescent dye that binds to DNA. Mycoplasmas are detected by their characteristic particulate or filamentous pattern of fluorescence on the cell surface and, if contamination is heavy, in surrounding areas. Mitochondria in the cytoplasm may be stained but are readily distinguished from mycoplasmas.

If for viral suspensions the interpretation of results is affected by marked cytopathic effects, the virus may be neutralised using a specific antiserum that has no inhibitory effects on mycoplasmas or a cell culture substrate that does not allow growth of the virus may be used. To demonstrate the absence of inhibitory effects of serum, carry out the positive control tests in the presence and absence of the antiserum.

VERIFICATION OF THE SUBSTRATE

Use Vero cells or another cell culture (for example, the production cell line) that is equivalent in effectiveness for detecting mycoplasmas. Test the effectiveness of the cells to be used by applying the procedure shown below and inoculating not more than 100 CFU or CFU-like micro-organisms of suitable reference strains of *M. hyorhinis* and *M. orale*. The following strains have been found to be suitable:

M. hyorhinis			ATCC 29052
M. orale	NCTC 10112	CIP 104969	ATCC 23714

The cells are suitable if both reference strains are detected.

The indicator cells must be subcultured without an antibiotic before use in the test.

TEST METHOD

1. Seed the indicator cell culture at a suitable density (for example, 2×10^4 to 2×10^5 cells/mL, 4×10^3 to 2.5×10^4 cells/cm^2) that will yield confluence after 3 days of growth. Inoculate 1 mL of the product to be examined into the cell culture vessel and incubate at 35-38 °C.

2. After at least 3 days of incubation, when the cells have grown to confluence, make a subculture on cover slips in suitable containers or on some other surface (for example, chambered slides) suitable for the test procedure. Seed the cells at low density so that they reach 50 per cent confluence after 3-5 days of incubation. Complete confluence impairs visualisation of mycoplasmas after staining and must be avoided.

3. Remove the medium and rinse the indicator cells with *phosphate buffered saline pH 7.4 R*, then add a suitable fixing solution (a freshly prepared mixture of 1 volume of *glacial acetic acid R* and 3 volumes of *methanol R* is suitable when *bisbenzimide R* is used for staining).

4. Remove the fixing solution and wash the cells with sterile *water R*. Dry the slides completely if they are to be stained more than 1 h later (particular care is needed for staining of slides after drying owing to artefacts that may be produced).

5. Add a suitable DNA stain and allow to stand for a suitable time (*bisbenzimide working solution R* and a standing time of 10 min are suitable).

6. Remove the stain and rinse the monolayer with *water R*.

7. Mount each coverslip, where applicable (a mixture of equal volumes of *glycerol R* and *phosphate-citrate buffer solution pH 5.5 R* is suitable for mounting). Examine by fluorescence (for bisbenzimide stain a 330 nm/380 nm excitation filter and an LP 440 nm barrier filter are suitable) at 400 × magnification or greater.

8. Compare the microscopic appearance of the test cultures with that of the negative and positive controls, examining for extranuclear fluorescence. Mycoplasmas produce pinpoints or filaments over the indicator cell cytoplasm. They may also produce pinpoints and filaments in the intercellular spaces. Multiple microscopic fields are examined according to the protocol established during validation.

INTERPRETATION OF RESULTS

The product to be examined complies with the test if fluorescence typical of mycoplasmas is not present. The test is invalid if the positive controls do not show fluorescence typical of mycoplasmas. The test is invalid if the negative controls show fluorescence typical of mycoplasmas.

NUCLEIC ACID AMPLIFICATION TECHNIQUES (NAT)

NAT (*2.6.21*) may be used for detection of mycoplasmas by amplification of nucleic acids extracted from a test sample with specific primers that reveal the presence of the target nucleic acid. NAT indicate the presence of a particular nucleic acid sequence and not necessarily the presence of viable mycoplasmas. A number of different techniques are available. This general chapter does not prescribe a particular method for the test. The procedure applied must be validated as described, taking account of the guidelines presented at the end of this section. Where a commercial kit is used, certain elements of the validation may be carried out by the manufacturer and information provided to the user but it must be remembered that full information on the primers may not be available and that production of the kit may be modified or discontinued.

NAT are applied where prescribed in a monograph. They may also be used instead of the culture method and the indicator cell culture method after suitable validation.

Direct NAT Can be applied in the presence of cytotoxic material and where a rapid method is needed.

Cell-culture enrichment followed by NAT The test sample and a suitable cell substrate (as described under the indicator cell-culture method) are cultured together for a suitable period; the nucleic acids are then extracted from cells and supernatant and used for detection by NAT.

VALIDATION

Reference standards are required at various stages during validation and for use as controls during routine application of the test. The reference standards may be mycoplasmas or nucleic acids.

For validation of the limit of detection, the following species represent an optimal selection in terms of the frequency of occurrence as contaminants and phylogenetic relationships:

— *A. laidlawii*;
— *M. fermentans*;
— *M. hyorhinis* (where cell-culture enrichment is used, a fastidious strain such as ATCC 29052 is included);
— *M. orale*;
— *M. pneumoniae* or *M. gallisepticum*;
— *M. synoviae* (where there is use of or exposure to avian material during production);
— *Mycoplasma arginini*;
— *Spiroplasma citri* (where there is use of or exposure to insect or plant material during production).

Demonstration of specificity requires the use of a suitable range of bacterial species other than mycoplasmas. Bacterial genera with close phylogenetic relation to mycoplasmas are most appropriate for this validation; these include *Clostridium*, *Lactobacillus* and *Streptococcus*.

Comparability studies for use of NAT as an alternative method For each mycoplasma test species:

— as an alternative to the culture method: the NAT test system must be shown to detect 10 CFU/mL;
— as an alternative to the indicator cell culture method: the NAT test system must be shown to detect 100 CFU/mL;

or an equivalent limit of detection in terms of the number of copies of mycoplasma nucleic acid in the test sample (using suitable reference standards of mycoplasma nucleic acid).

CONTROLS

Internal controls

Internal controls are necessary for routine verification of absence of inhibition. The internal control may contain the primer binding-site, or some other suitable sequence may be used. It is preferably added to the test material before isolating the nucleic acid and therefore acts as an overall control (extraction, reverse transcription, amplification, detection).

External controls

The external positive control contains a defined number of target-sequence copies or CFUs from 1 or more suitable species of mycoplasma chosen from those used during validation of the test conditions. 1 of the positive controls is set close to the positive cut-off point to demonstrate that the expected sensitivity is achieved. The external negative control contains no target sequence but does not necessarily represent the same matrix as the test article.

INTERPRETATION OF RESULTS

The primers used may also amplify non-mycoplasmal bacterial nucleic acid, leading to false positive results. Procedures are established at the time of validation for dealing with confirmation of positive results, where necessary.

The following section is published for information.

VALIDATION OF NUCLEIC ACID AMPLIFICATION TECHNIQUES (NAT) FOR THE DETECTION OF MYCOPLASMAS: GUIDELINES

1 SCOPE

Nucleic acid amplification techniques (NAT) are either qualitative or quantitative tests for the presence of nucleic acid. For the detection of mycoplasma contamination of various samples such as vaccines and cell substrates, qualitative tests are adequate and may be considered to be limit tests.

These guidelines describe methods to validate qualitative nucleic acid amplification analytical procedures for assessing mycoplasma contamination. They may also be applicable for real-time NAT used as limit tests for the control of contaminants.

The 2 characteristics regarded as the most important for validation of the analytical procedure are the specificity and the detection limit. In addition, the robustness of the analytical procedure should be evaluated.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part or all of the analytical procedure, documented validation points already covered by the kit manufacturer can replace validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. detection limit, robustness, cross-detection of other classes of bacteria).

NAT may be used as:

— a complementary test (for example, for cytotoxic viral suspensions) or for in-process control purposes;

— an alternative method to replace an official method (indicator cell culture method or culture method).

These guidelines will thus separate these 2 objectives by presenting first a guideline for the validation of the NAT themselves, and second, a guideline for a comparability study between NAT and official methods.

2 GUIDELINE FOR MYCOPLASMA NAT VALIDATION

3 parameters should be evaluated: specificity, detection limit and robustness.

2-1 Specificity

Specificity is the ability to unequivocally assess target nucleic acid in the presence of components that may be expected to be present.

The specificity of NAT is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and detection steps).

The ability of the NAT to detect a large panel of mycoplasma species will depend on the choice of primers, probes and method parameters. This ability should be demonstrated using characterised reference panels (e.g. reference strains provided by the EDQM). Since NAT systems are usually based on a mix of primers, the theoretical analysis of primers and probes by comparison with databases is not recommended, because interpretation of the results may be quite complex and may not reflect the experimental results.

Moreover, as it is likely that the primers will detect other bacterial species, the potential cross-detection should be documented in the validation study. Bacterial genera such as gram-positive bacteria with close phylogenetic relation to mycoplasmas are most appropriate for this validation; these include *Clostridium*, *Lactobacillus* and *Streptococcus*. However, this is not an exhaustive list and species to be tested will depend on the theoretical ability (based on primers/probes sequences) of the NAT system to detect such other species.

Based on the results from this validation of the specificity, if a gap in the specificity of the method is identified (such as detection of non-mycoplasmal bacterial nucleic acid), an appropriate strategy must be proposed in the validation study to allow interpretation of positive results on a routine basis. For example, a second test may be performed using an alternative method without this specificity gap or using an official method.

2-2 Detection limit

The detection limit of an individual analytical procedure is the lowest amount of target nucleic acid in a sample that can be detected but not necessarily quantitated as an exact value.

For establishment of the detection limit, a positive cut-off point should be determined for the nucleic acid amplification analytical procedure. The positive cut-off point (as defined in general chapter *2.6.21*) is the minimum number of target sequence copies per volume of sample that can be detected in 95 per cent of test runs. This positive cut-off point is influenced by the distribution of mycoplasmal genomes in the individual samples being tested and by factors such as enzyme efficiency, and can result in different 95 per cent cut-off values for individual analytical test runs.

To determine the positive cut-off point, a dilution series of characterised and calibrated (either in CFUs or nucleic acid copies) in-house working strains or EDQM standards should be tested on different days to examine variation between test runs.

For validation of the limit of detection, the following species represent an optimal selection in terms of the frequency of occurrence as contaminants and phylogenetic relationships:
— *A. laidlawii*;
— *M. fermentans*;
— *M. hyorhinis*;
— *M. orale*;
— *M. pneumoniae* or *M. gallisepticum*;
— *M. synoviae* (where there is use of or exposure to avian material during production);
— *M. arginini*;
— *S. citri* (where there is use of or exposure to insect or plant material during production).

For each strain, at least 3 independent 10-fold dilution series should be tested, with a sufficient number of replicates at each dilution to give a total number of 24 test results for each dilution, to enable a statistical analysis of the results.

For example, a laboratory may test 3 dilution series on different days with 8 replicates for each dilution, 4 dilution series on different days with 6 replicates for each dilution, or 6 dilution series on different days with 4 replicates for each dilution. In order to keep the number of dilutions at a manageable level, a preliminary test should be performed to obtain a preliminary value for the positive cut-off point (i.e. the highest dilution giving a positive signal). The range of dilutions can then be chosen around the predetermined preliminary cut-off point. The concentration of mycoplasmas (CFUs or copies) that can be detected in 95 per cent of test runs can then be calculated using an appropriate statistical evaluation.

These results may also serve to evaluate the variability of the analytical procedure.

2-3 Robustness

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters, and provides an indication of its reliability during normal usage.

The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. However, the robustness of the method can be demonstrated during its development when small variations in the concentrations of reagents (e.g. $MgCl_2$, primers or deoxyribonucleotides) are tested. Modifications of extraction kits or extraction procedures as well as different thermal cycler types may also be evaluated.

Finally, robustness of the method can be evaluated through collaborative studies.

3 GUIDELINE FOR COMPARABILITY STUDY

NAT may be used instead of official methods (indicator cell culture method and/or culture method). In this case a comparability study should be carried out. This comparability study should include mainly a comparison of the respective detection limits of the alternative method and official methods. However, specificity (mycoplasma panel detected, putative false positive results) should also be considered.

For the detection limit, acceptability criteria are defined as follows:
— if the alternative method is proposed to replace the culture method, the NAT system must be shown to detect 10 CFU/mL for each mycoplasma test species described in paragraph 2-2;
— if the alternative method is proposed to replace the indicator cell culture method, the NAT system must be shown to detect 100 CFU/mL for each mycoplasma test species described in paragraph 2-2

For both cases, suitable standards calibrated for the number of nucleic acid copies and the number of CFUs may be used for establishing that these acceptability criteria are reached. The relation between CFUs and nucleic acid copies for the reference preparations should be previously established to compare the performance of the alternative NAT method with the performance of the official methods.

1 of the following 2 strategies can be used to perform this comparability study:
— perform the NAT alternative method in parallel with the official method(s) to evaluate simultaneously the detection limit of both methods using the same samples of calibrated strains;
— compare the performance of the NAT alternative method using previously obtained data from official method validation. In this case, calibration of standards used for both validations as well as their stabilities should be documented carefully.

Comparability study reports should describe all the validation elements described in section 2 (specificity, limit of detection and variability, as well as robustness) in order to assess all the advantages and/or disadvantages of the alternative NAT method compared to official methods.

4. Mycobacteria

(Ph. Eur. method 2.6.2)

If the sample to be examined may be contaminated by micro-organisms other than mycobacteria, treat it with a suitable decontamination solution, such as acetylcysteine-sodium hydroxide solution or sodium laurilsulfate solution.

Inoculate 0.2 mL of the sample in triplicate onto each of 2 suitable solid media (Löwenstein-Jensen medium and Middlebrook 7H10 medium are considered suitable). Inoculate 0.5 mL in triplicate into a suitable liquid medium. Incubate all media at 37 °C for 56 days.

Establish the fertility of the media in the presence of the preparation to be examined by inoculation of a suitable strain of a *Mycobacterium* sp. such as BCG and if necessary use a suitable neutralising substance.

If contaminating micro-organisms develop during the first 8 days of incubation, repeat the test and carry out at the same time a bacteriological sterility test.

If at the end of the incubation time no growth of mycobacteria occurs in any of the test media, the preparation complies with the test.

5. Extraneous Agents in Viral Vaccines

(Ph. Eur. method 2.6.16)

INTRODUCTION

A strategy for testing extraneous agents in viral vaccines must be developed based on a risk assessment following the principles of viral contamination risk detailed in general chapter *5.1.7. Viral safety*. This strategy includes a full package of suitable tests that are able to detect different families of extraneous agents that may infect the source of virus strains including cell substrates and raw material of animal or plant origin. It also takes into account the capacity of the manufacturing process to remove or inactivate viruses. The list of tests summarised in Table 2.6.16.-1 must be adapted depending on the extraneous agents that have the potential to contaminate the product: for *in vitro* tests, the risk assessment may allow, with the agreement of the competent authority, the use of other permissive cell lines or

molecular biology methods depending on the manufacturing process and the incubation temperature for the growth of particular viruses. If *in vivo* tests are more relevant than *in vitro* tests for the detection of some adventitious viruses (e.g. suckling mice for the vesicular stomatitis virus and fertilised SPF eggs for the influenza virus) the decision to maintain or to introduce such *in vivo* assays in a testing strategy must be justified by the risk assessment.

New, sensitive molecular methods with broad detection capabilities are available. These new approaches include high-throughput sequencing (HTS) methods, nucleic acid amplification techniques (NAT) (e.g. polymerase chain reaction (PCR), reverse transcriptase PCR (RT-PCR), product-enhanced reverse transcriptase (PERT) assays) for whole virus families or random-priming methods (associated or not with sequencing), hybridisation to oligonucleotide arrays, and mass spectrometry with broad-spectrum PCR. These methods may be used either as an alternative to *in vivo* tests and specific NAT or as a supplement/alternative to *in vitro* culture tests based on the risk assessment and with the agreement of the competent authority.

In tests that require prior neutralisation of the virus, use specific antibodies of non-human, non-simian origin; if the virus has been propagated in avian tissues, the antibodies must also be of non-avian origin. To prepare antiserum, use an immunising antigen produced in cell cultures from a species different from that used for the production of the vaccine and free from extraneous agents. Where the use of SPF eggs is prescribed, the eggs are obtained from a flock free from specified pathogens (*5.2.2*).

TEST METHODS

Relevant tests for extraneous agents to be carried out at various production stages are indicated in Table 2.6.16.-1 using the methods described below, based on the risk assessment.

Take samples at the time of harvesting, and if not tested immediately, keep at a temperature below −40 °C.

Bacterial and fungal contamination

Each virus seed lot and virus harvest complies with the test for sterility (*2.6.1*).

Mycoplasmas (*2.6.7*)

Each virus seed lot and virus harvest complies with the test for mycoplasmas.

Spiroplasmas

Spiroplasmas may be introduced into virus seed lots through contamination of raw materials of plant origin or when insect cell lines are used for virus propagation. When appropriate, virus seed lots are demonstrated to be free of spiroplasmas using a validated method approved by the competent authority. NAT methods for detection of mycoplasmas (*2.6.7*) may be used to detect spiroplasmas after validation and agreement from the competent authority.

Mycobacteria (*2.6.2*)

A 2.7 mL sample of each virus seed lot and each virus harvest is tested for the presence of *Mycobacterium* spp. by culture methods known to be sensitive for the detection of these organisms. NAT (*2.6.21*) may be used as an alternative, provided such an assay is validated and shown to be comparable to the culture method.

Test in suckling mice

Each virus seed lot is tested in suckling mice if the risk assessment indicates that this test provides a risk mitigation, taking into account the overall testing package. Inoculate no fewer than 20 suckling mice, each less than 24 h old, intracerebrally with 0.01 mL and intraperitoneally with at least 0.1 mL of the virus seed lot. Observe the suckling mice daily for at least 4 weeks. Carry out an autopsy of all suckling mice that die after the first 24 h of the test or that show signs of illness, and examine for evidence of viral infection by direct macroscopical observation. The virus seed lot passes the test if no suckling mice show evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the original inoculated suckling mice survive the observation period.

Table 2.6.16.-1. – *Relevant tests for extraneous agents at various production stages*

	Virus seed lots	Virus harvests	Production of culture substrates	
			Control cells	Control eggs
Bacterial and fungal contamination	+	+	-	-
Mycoplasmas	+	+	-	-
Spiroplasmas(1)	+	-	-	-
Mycobacteria	+	+	-	-
Test in suckling mice(2)	+	-	-	-
Avian viruses(3)	+	+	-	-
Test for extraneous agents in cell cultures(4)	+	+	+	+
Insect viruses(5)	+	+	-	-
Test on control cells (microscopic examination)	-	-	+	-
Haemadsorbing viruses	-	-	+	-
Test on control eggs (haemagglutinating agents)	-	-	-	+
Avian leucosis viruses(6)	-	-	+	+
Test for specific viruses by NAT(7)	+	+	-	-
Test for viruses using broad molecular methods(8)	+	+	-	-

(1) If insect cells or raw materials of plant origin are used.
(2) If the risk assessment indicates that this test provides a risk mitigation taking into account the overall testing package.
(3) If the virus is propagated in avian or primary avian tissues. If the risk assessment indicates that this test provides a risk mitigation taking into account the overall testing package.
(4) Test performed in suitable permissive cell cultures. Based on a risk assessment.
(5) If the virus is propagated in insect cells.
(6) If the virus is propagated in primary avian tissues or in eggs.
(7) Based on a risk assessment.
(8) These methods may be used either as an alternative to *in vivo* tests and specific NAT or as a supplement/alternative to *in vitro* culture tests based on the risk assessment and in agreement with the competent authority.

Avian viruses

Each virus seed lot propagated in avian tissues and each virus harvest propagated in primary avian tissues is tested for avian viruses if the risk assessment indicates that this test provides a risk mitigation taking into account the overall testing package. Neutralise a sample equivalent to 100 human doses of vaccine or 10 mL, whichever is the greater. Using 0.5 mL per egg, inoculate a group of fertilised SPF eggs, 9-11 days

old, by the allantoic route and a second group, 5-7 days old, into the yolk sac. Incubate for 7 days. The virus seed lot or harvest complies with the test if the allantoic and yolk sac fluids show no sign of the presence of any haemagglutinating agent and if all embryos and chorio-allantoic membranes examined for gross pathology, are normal. The test is not valid unless at least 80 per cent of the inoculated eggs survive for 7 days.

Test for extraneous agents in cell cultures

For each virus seed lot, each virus harvest and each production cell culture (control cells or control eggs), tests for other extraneous agents must be carried out based on a risk assessment. The origin of the cell substrate and virus strain, as well as the potential extraneous agents that may be inadvertently introduced during production processes or through the use of animal- or plant-derived raw materials, must be taken into account when choosing suitable permissive cells.

For each virus seed lot and virus harvest, neutralised samples, equivalent (unless otherwise prescribed) to 500 human doses of vaccine or 50 mL, whichever is the greater, are tested for the presence of extraneous agents by inoculation into continuous simian and human cell cultures. If the virus is grown in simian or human cells, the neutralised virus harvest is tested on a separate culture of these cells. If the virus is grown in a mammalian cell system other than simian or human, or in avian cells, cells of that species, but from a separate batch, are also inoculated. The cells are incubated at 36 ± 1 °C and observed for a period of 14 days. If the production cell culture is maintained at a temperature other than 36 ± 1 °C, a supplementary test for extraneous agents is carried out at the production temperature using the same type of cells used for growth of the virus. A subculture of 14 days is carried out followed by a haemadsorbing test. The virus seed lot or harvest passes the tests if none of the cell cultures show evidence of the presence of any extraneous agents after 14 and 28 days of incubation, and no evidence of any haemadsorbing viruses after 28 days. The test is not valid unless at least 80 per cent of the cell cultures remain viable.

Insect viruses

Each virus seed lot and virus harvest propagated in insect cells is tested for insect viruses. Neutralised samples, equivalent (unless otherwise prescribed) to 500 human doses of vaccine or 50 mL, whichever is the greater, are tested for the presence of extraneous agents by inoculation into at least 1 cell culture different from that used in production and permissible to insect viruses, and that also allows detection of human arboviruses (e.g. BHK-21). The choice of cells is approved by the competent authority and takes into account the origin of the production cells and the likely contaminants that may be detected by the chosen cells. The cells are incubated at an appropriate temperature and observed for a period of 14 days. A subculture of 14 days is carried out followed by a haemadsorbing test. The virus seed lot or harvest passes the tests if none of the cell cultures show evidence of the presence of any extraneous agents after 14 and 28 days of incubation, and no evidence of any haemadsorbing virus after 28 days. The test is not valid unless at least 80 per cent of the cell cultures remain viable.

Tests on control cells

Where cell cultures are used for virus production, examine the control cells microscopically for the absence of any virus causing cytopathic degeneration throughout the incubation time of the inoculated production cell cultures or for no less than 14 days beyond the time of inoculation of the production vessels, whichever is the longer. The test is not valid unless at least 80 per cent of the control cell cultures survive to the end of the observation period.

At 14 days or at the time of the last virus harvest, whichever is the longer, pool the supernatant fluids from the control cells and examine for the presence of extraneous agents over a period of 14 days as described above for the virus seed lot and the virus harvest by inoculation of relevant cell cultures depending on the type of cells used for virus growth.

Haemadsorbing viruses

Where cell cultures are used for virus production, a microscopic examination of the control cells is carried out as described above for the test for extraneous agents in cell cultures. At 14 days or at the time of the last virus harvest, whichever is the longer, examine no fewer than 25 per cent of the control cultures for the presence of haemadsorbing viruses by the addition of guinea-pig red blood cells. If the test for haemadsorbing viruses is not feasible, carry out a test for haemagglutinating viruses. If the guinea-pig red blood cells have been stored, they shall have been stored at 5 ± 3 °C for not more than 7 days. Read half of the cultures after incubation at 5 ± 3 °C for 30 min and the other half after incubation at 20-25 °C for 30 min. No evidence of haemadsorbing agents is found.

Tests on control eggs

Where eggs are used for virus production, examine 0.25 mL of the allantoic fluid from each control egg for haemagglutinating agents by mixing directly with chicken red blood cells and after a passage in SPF eggs carried out as follows: inoculate a 5 mL sample of the pooled amniotic fluids from the control eggs in 0.5 mL volumes into the allantoic cavity and into the amniotic cavity of SPF eggs. The control eggs comply with the test if no evidence of the presence of haemagglutinating agents is found in either test.

In addition, inoculate 5 mL samples of the pooled amniotic fluids from the control eggs into suitable permissive cells including human, simian and avian cells. Observe the cell cultures for 14 days at a suitable incubation temperature. The control eggs comply with the test if no evidence of the presence of extraneous agents is found. The test is not valid unless 80 per cent of the inoculated cultures survive to the end of the observation period.

Avian leucosis viruses

For each virus propagated in primary avian cell tissues or in eggs, the production cell culture (control cells or control eggs) is tested for avian leucosis viruses. When cell cultures are used for virus production, a microscopic examination of the control cells is carried out as described above for the test for extraneous agents prior to the test for avian leucosis viruses. At 14 days or at the time of the last virus harvest, whichever is the longer, carry out the test for avian leucosis viruses on DF-1 cells or leucosis-free chick-embryo cell cultures with amplification through 5 passages using at least 5 mL of the supernatant fluid from the control cells or at least 10 mL of a sample of the pooled amniotic fluids from the control eggs. PERT assay end-point can be used after DF-1 amplification for detection of exogenous avian retroviruses (including avian leucosis virus). For specific detection of avian leucosis virus, several end-points can be used such as immunostaining, enzyme-linked immunosorbent assay (ELISA) or complement fixation for avian leucosis (COFAL). Control cells or control eggs comply with the test if there is no evidence of the presence of any avian leucosis virus.

Tests for specific viruses by NAT

Based on a risk assessment related to the manufacturing process, each virus seed lot and each virus harvest may be tested by NAT (*2.6.21*) for specific viruses that are not detected by conventional *in vivo* or cell culture assays.

Test for viruses using broad molecular methods

With the agreement of the competent authority, broad molecular methods (e.g. HTS) may be used either as an alternative to *in vivo* tests and specific NAT, or as a supplement/alternative to *in vitro* culture tests based on the risk assessment.

Both NAT (*2.6.21*) and broad molecular methods are carried out with or without prior amplification in suitable permissive cells. In cases of positive results with either broad molecular methods or NAT, a follow-up investigation must be conducted to determine whether detected nucleic acids are due to the presence of infectious extraneous agents and/or are known to constitute a risk to human health.

C. Efficacy of Antimicrobial Preservation

(Ph. Eur. general texts 5.1.3)

If a pharmaceutical preparation does not itself have adequate antimicrobial activity, antimicrobial preservatives may be added, particularly to aqueous preparations, to prevent proliferation or to limit microbial contamination which, during normal conditions of storage and use, particularly for multidose containers, could occur in a product and present a hazard to the patient from infection and spoilage of the preparation. Antimicrobial preservatives must not be used as a substitute for good manufacturing practice.

The efficacy of an antimicrobial preservative may be enhanced or diminished by the active constituent of the preparation or by the formulation in which it is incorporated or by the container and closure used. The antimicrobial activity of the preparation in its final container is investigated over the period of validity to ensure that such activity has not been impaired by storage. Such investigations may be carried out on samples removed from the final container immediately prior to testing.

During development of a pharmaceutical preparation, it shall be demonstrated that the antimicrobial activity of the preparation as such or, if necessary, with the addition of a suitable preservative or preservatives provides adequate protection from adverse effects that may arise from microbial contamination or proliferation during storage and use of the preparation.

The efficacy of the antimicrobial activity may be demonstrated by the test described below. The test is not intended to be used for routine control purposes.

TEST FOR EFFICACY OF ANTIMICROBIAL PRESERVATION

The test consists of challenging the preparation, wherever possible in its final container, with a prescribed inoculum of suitable micro-organisms, storing the inoculated preparation at a prescribed temperature, withdrawing samples from the container at specified intervals of time and counting the organisms in the samples so removed.

The preservative properties of the preparation are adequate if, in the conditions of the test, there is a significant fall or no increase, as appropriate, in the number of micro-organisms in the inoculated preparation after the times and at the temperatures prescribed. The acceptance criteria, in terms of decrease in the number of micro-organisms with time, vary for different types of preparations according to the degree of protection intended (see Tables 5.1.3.-1/2/3).

Test micro-organisms

Pseudomonas aeruginosa	ATCC 9027; NCIMB 8626; CIP 82.118.
Staphylococcus aureus	ATCC 6538; NCTC 10788; NCIMB 9518; CIP 4.83.
Candida albicans	ATCC 10231; NCPF 3179; IP 48.72.
Aspergillus brasiliensis	ATCC 16404; IMI 149007; IP 1431.83.

Single-strain challenges are used and the designated micro-organisms are supplemented, where appropriate, by other strains or species that may represent likely contaminants to the preparation. It is recommended, for example, that *Escherichia coli* (ATCC 8739; NCIMB 8545; CIP 53.126) is used for all oral preparations and *Zygosaccharomyces rouxii* (NCYC 381; IP 2021.92) for oral preparations containing a high concentration of sugar.

Preparation of inoculum

Preparatory to the test, inoculate the surface of casein soya bean digest agar (*2.6.12*) for bacteria or Sabouraud-dextrose agar without the addition of antibiotics (*2.6.12*) for fungi, with the recently grown stock culture of each of the specified micro-organisms. Incubate the bacterial cultures at 30-35 °C for 18-24 h, the culture of *C. albicans* at 20-25 °C for 48 h, and the culture of *A. brasiliensis* at 20-25 °C for 1 week or until good sporulation is obtained. Subcultures may be needed after revival before the micro-organism is in its optimal state, but it is recommended that their number be kept to a minimum.

To harvest the bacterial and *C. albicans* cultures, use a sterile suspending fluid, containing 9 g/L of *sodium chloride R*, for dispersal and transfer of the surface growth into a suitable vessel. Add sufficient suspending fluid to reduce the microbial count to about 10^8 micro-organisms per millilitre. To harvest the *A. brasiliensis* culture, use a sterile suspending fluid containing 9 g/L of *sodium chloride R* and 0.5 g/L of *polysorbate 80 R* and adjust the spore count to about 10^8 per millilitre by adding the same solution.

Remove immediately a suitable sample from each suspension and determine the number of colony-forming units per millilitre in each suspension by plate count or membrane filtration (*2.6.12*). This value serves to determine the inoculum and the baseline to use in the test. The suspensions shall be used immediately.

METHOD

To count the viable micro-organisms in the inoculated products, use the agar medium used for the initial cultivation of the respective micro-organisms.

Inoculate a series of containers of the product to be examined, each with a suspension of one of the test organisms to give an inoculum of 10^5 to 10^6 micro-organisms per millilitre or per gram of the preparation. The volume of the suspension of inoculum does not exceed 1 per cent of the volume of the product. Mix thoroughly to ensure homogeneous distribution.

Maintain the inoculated product at 20-25 °C, protected from light. Remove a suitable sample from each container, typically 1 mL or 1 g, at zero hour and at appropriate intervals according to the type of the product and determine the number of viable micro-organisms by plate count or membrane filtration (*2.6.12*). Ensure that any residual antimicrobial activity of the product is eliminated by dilution, by filtration or by the use of a specific inactivator. When dilution procedures are used, due allowance is made for the

reduced sensitivity in the recovery of small numbers of viable micro-organisms. When a specific inactivator is used, the ability of the system to support the growth of the test organisms is confirmed by the use of appropriate controls.

The procedure is validated to verify its ability to demonstrate the required reduction in count of viable micro-organisms.

ACCEPTANCE CRITERIA

The criteria for evaluation of antimicrobial activity are given in Tables 5.1.3.-1/2/3 in terms of the log_{10} reduction in the number of viable micro-organisms against the value obtained for the inoculum.

Table 5.1.3.-1. - *Parenteral preparations, eye preparations, intrauterine preparations and intramammary preparations*

		Log_{10} reduction				
		6 h	24 h	7 d	14 d	28 d
Bacteria	A	2	3	-	-	NR
	B	-	1	3	-	NI
Fungi	A	-	-	2	-	NI
	B	-	-	-	1	NI

NR: no recovery.
NI: no increase in number of viable micro-organisms compared to the previous reading.

The A criteria express the recommended efficacy to be achieved. In justified cases where the A criteria cannot be attained, for example for reasons of an increased risk of adverse reactions, the B criteria must be satisfied.

Table 5.1.3.-2. - *Ear preparations, nasal preparations, preparations for cutaneous application and preparations for inhalation*

		Log_{10} reduction			
		2 d	7 d	14 d	28 d
Bacteria	A	2	3	-	NI
	B	-	-	3	NI
Fungi	A	-	-	2	NI
	B	-	-	1	NI

NI: no increase in number of viable micro-organisms compared to the previous reading.

The A criteria express the recommended efficacy to be achieved. In justified cases where the A criteria cannot be attained, for example for reasons of an increased risk of adverse reactions, the B criteria must be satisfied.

Table 5.1.3.-3. - *Oral preparations, oromucosal preparations and rectal preparations*

	Log_{10} reduction	
	14 d	28 d
Bacteria	3	NI
Fungi	1	NI

NI: no increase in number of viable micro-organisms compared to the previous reading.

The above criteria express the recommended efficacy to be achieved.

D. Microbiological Quality of Non-sterile Pharmaceutical Preparations and Substances for Pharmaceutical Use[1]

(Ph. Eur. general texts 5.1.4)

◊This chapter does not apply to products containing viable micro-organisms as active ingredients.◊

The presence of certain micro-organisms in non-sterile preparations may have the potential to reduce or even inactivate the therapeutic activity of the product and has a potential to adversely affect the health of the patient. Manufacturers therefore have to ensure a low bioburden of finished dosage forms by implementing current guidelines on Good Manufacturing Practice during the manufacture, storage and distribution of pharmaceutical preparations.

Microbial examination of non-sterile products is performed according to the methods given in general chapters *2.6.12* and *2.6.13*. Acceptance criteria for non-sterile pharmaceutical products based upon the total aerobic microbial count (TAMC) and the total combined yeasts/moulds count (TYMC) are given in Tables 5.1.4.-1 and 5.1.4.-2. Acceptance criteria are based on individual results or on the average of replicate counts when replicate counts are performed (e.g. direct plating methods).

When an acceptance criterion for microbiological quality is prescribed it is interpreted as follows:
- 10^1 CFU: maximum acceptable count = 20;
- 10^2 CFU: maximum acceptable count = 200;
- 10^3 CFU: maximum acceptable count = 2000, and so forth.

Table 5.1.4.-1 includes a list of specified micro-organisms for which acceptance criteria are set. The list is not necessarily exhaustive and for a given preparation it may be necessary to test for other micro-organisms depending on the nature of the starting materials and the manufacturing process.

If it has been shown that none of the prescribed tests will allow valid enumeration of micro-organisms at the level prescribed, a validated method with a limit of detection as close as possible to the indicated acceptance criterion is used.

In addition to the micro-organisms listed in Table 5.1.4.-1, the significance of other micro-organisms recovered is evaluated in terms of:
- use of the product: hazard varies according to the route of administration (eye, nose, respiratory tract);
- nature of the product: its ability to support growth, the presence of adequate antimicrobial preservation;
- method of application;
- intended recipient: risk may differ for neonates, infants, the debilitated;
- use of immunosuppressive agents, corticosteroids;
- presence of disease, wounds, organ damage.

Where warranted, a risk-based assessment of the relevant factors is conducted by personnel with specialised training in microbiology and the interpretation of microbiological data. For raw materials, the assessment takes account of processing to which the product is subjected, the current technology of testing and the availability of materials of the desired quality.

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

Table 5.1.4.-1. – *Acceptance criteria for microbiological quality of non-sterile dosage forms*

Route of administration	TAMC (CFU/g or CFU/mL)	TYMC (CFU/g or CFU/mL)	Specified micro-organisms
Non-aqueous preparations for oral use	10^3	10^2	Absence of *Escherichia coli* (1 g or 1 mL)
Aqueous preparations for oral use	10^2	10^1	Absence of *Escherichia coli* (1 g or 1 mL)
Rectal use	10^3	10^2	-
Oromucosal use Gingival use Cutaneous use Nasal use Auricular use	10^2	10^1	Absence of *Staphylococcus aureus* (1 g or 1 mL) Absence of *Pseudomonas aeruginosa* (1 g or 1 mL)
Vaginal use	10^2	10^1	Absence of *Pseudomonas aeruginosa* (1 g or 1 mL) Absence of *Staphylococcus aureus* (1 g or 1 mL) Absence of *Candida albicans* (1 g or 1 mL)
Transdermal patches (limits for 1 patch including adhesive layer and backing)	10^2	10^1	Absence of *Staphylococcus aureus* (1 patch) Absence of *Pseudomonas aeruginosa* (1 patch)
◊Orodispersible films (limits for 1 film)	10^2	10^1	Absence of *Escherichia coli* (1 film) Absence of *Staphylococcus aureus* (1 film) Absence of *Pseudomonas aeruginosa* (1 film)◊
Inhalation use (special requirements apply to liquid preparations for nebulisation)	10^2	10^1	Absence of *Staphylococcus aureus* (1 g or 1 mL) Absence of *Pseudomonas aeruginosa* (1 g or 1 mL) Absence of bile-tolerant gram-negative bacteria (1 g or 1 mL)
♦Special Ph. Eur. provision for oral dosage forms containing raw materials of natural (animal, vegetal or mineral) origin for which antimicrobial pretreatment is not feasible and for which the competent authority accepts TAMC of the raw material exceeding 10^3 CFU/g or CFU/mL.	10^4	10^2	Not more than 10^2 CFU of bile-tolerant gram-negative bacteria (1 g or 1 mL) Absence of *Salmonella* (10 g or 10 mL) Absence of *Escherichia coli* (1 g or 1 mL) Absence of *Staphylococcus aureus* (1 g or 1 mL)♦
♦Special Ph. Eur. provision for premixes for medicated feeding stuffs for veterinary use using excipients of plant origin for which antimicrobial treatment is not feasible.	10^5	10^4	Not more than 10^4 CFU of bile-tolerant gram-negative bacteria (1 g or 1 mL) Absence of *Escherichia coli* (1 g or 1 mL) Absence of *Salmonella* (25 g or 25 mL)♦

Table 5.1.4.-2. – *Acceptance criteria for microbiological quality of non-sterile substances for pharmaceutical use*

	TAMC (CFU/g or CFU/mL)	TYMC (CFU/g or CFU/mL)
Substances for pharmaceutical use	10^3	10^2

♦*Recommended acceptance criteria for microbiological quality of herbal medicinal products for oral use and extracts used in their preparation are given in general chapter 5.1.8.*♦

E. Microbiological Examination of Cell-based Preparations

(Ph. Eur. method 2.6.27)

This chapter does not concern the examination of human blood or blood components, which is covered by Directive 2002/98/EC of the European Parliament and of the Council of 27 January 2003 and Commission Directive 2004/33/EC of 22 March 2004 implementing Directive 2002/98/EC.

1 INTRODUCTION

The approaches to microbiological examination of cell-based preparations outlined in this general chapter take into account the characteristics and limitations of these preparations, in particular their shelf-life, which may not always allow for completion of conventional microbiological examination tests before administration to the patient, as well as the amounts available for testing and sampling-related issues. These approaches may be applied when the test for sterility, described in general chapter *2.6.1. Sterility*, is required but cannot be performed for technical reasons or due to the characteristics of the specific cell-based preparation.

1-1 SHELF-LIFE

The shelf-life of cell-based preparations is dependent on the cell characteristics and on the preservation conditions.
For non-cryopreserved cell-based preparations, the shelf-life usually does not exceed 3-4 days and sometimes not more than a few hours. In such cases the microbiological status of the final preparation cannot be determined, according to general chapter *2.6.1*, before the time of administration.

1-2 SAMPLE COMPOSITION

Microbial contaminants may be found either inside or on the surface of cells or other components of the cell-based preparation and may not be detected if only supernatants, such as culture or transport media, are analysed. The sample tested must be representative of all of the components of the cell-based preparation, unless otherwise justified.

1-3 SAMPLE SIZE

Due to constraints surrounding the use of a single donor or manufacturing-related capacities, the sample volume available for testing at the end of the production process may be limited. Nevertheless, with regard to the sampling error, which may lead to microbial contamination not being

detected, the sample size must be sufficient to ensure suitable sensitivity and specificity of the chosen test method.

1-4 RATIONALE FOR METHOD SELECTION

Method selection must be based on the characteristics of the final preparation and the manufacturing process. To ensure safety for the intended use, the choice of method or combination of methods could be supported by a risk analysis of the potential exposure to microbiological contaminants, and the characteristics and intended use of the cell-based preparation. The media and incubation times used in these methods must be chosen taking into account the properties of the source material and the conditions during the manufacturing process that may support growth of specific micro-organisms (e.g. psychrophilic, thermophilic or fastidious bacteria or fungi). The composition of the cell-based preparation may impede certain test methods for physical reasons such as initial turbidity of the culture media after addition of the test sample.

The following approaches to microbiological examination may be applied:

— automated growth-based methods;
— a combination of preculturing and detection by alternative methods (*5.1.6*);
— direct detection by alternative methods (*5.1.6*);
— methods based on the sterility test prescribed in general chapter *2.6.1*.

2 GENERAL CONSIDERATIONS

2-1 GENERAL PRECAUTIONS

The test is carried out under aseptic conditions according to current regulations for potentially infective material.
The precautions taken to avoid contamination are such that they do not affect any micro-organisms that are to be revealed in the test. The test is performed under working conditions that are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls. Testing shall take account of the potential for the presence of inhibitory substances in the sample that may affect the outcome of the test.

2-2 HANDLING CONSTRAINTS

2-2-1 Shelf-life

'Negative-to-date' is understood as an intermediate reading of a test method (*2.6.1* or an automated growth-based method) that has not yet been completed. Where cell-based preparations have limiting shelf-lives, 'negative-to-date' results may be used as the readout, where justified. Based on the risk analysis of the characteristics and intended use of the cell-based preparation, results from additional microbiological in-process control may be needed at the time of use.

2-2-2 Sampling

The test sample must be representative of all of the components of the cell-based preparation and be taken from the final preparation. Where this is not possible, surrogate testing may be performed, for example on the liquids last in contact with the cells being processed.

3 METHODS FOR MICROBIOLOGICAL EXAMINATION OF CELL-BASED PREPARATIONS

3-1 AUTOMATED GROWTH-BASED METHOD

3-1-1 Growth promotion test

This section outlines the conditions for confirming the suitability of the culture media used for microbiological examination.

At least 2 suitable culture media intended for detection of fungi and aerobic and anaerobic bacteria are used. Each batch of sterile medium is tested for its growth-promoting capacities by inoculating duplicate test containers of each medium with not more than 100 CFU of each of the strains listed in Table 2.6.27.-1, and incubating for a maximum of 7 days for detection of microbial growth at the temperature defined for testing (see Table 2.6.27.-3). The test media are satisfactory if there is clear evidence of growth in all inoculated media containers within this incubation period.

Table 2.6.27.-1. – *Micro-organisms used for growth promotion test*

Aerobic medium	
Staphylococcus aureus	for example, ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518
Bacillus subtilis	for example, ATCC 6633, CIP 52.62, NCIMB 8054
Pseudomonas aeruginosa	for example, ATCC 9027, NCIMB 8626, CIP 82.118
Candida albicans	for example, ATCC 10231, IP 48.72, NCPF 3179
Aspergillus brasiliensis	for example, ATCC 16404, IP 1431.83, IMI 149007
Anaerobic medium	
Clostridium sporogenes	for example, ATCC 19404, CIP 79.3, NCTC 532 or ATCC 11437
Bacteroides fragilis	for example, ATCC 25285, CIP 77.16, NCTC 9343

3-1-2 Method suitability

For a validated automated growth-based method only a confirmation of the suitability of the method for the given cell-based preparation must be performed with respect to specificity (absence of false positive results), sensitivity, reproducibility and robustness. Regardless of the type of cell-based preparation, the manufacturing process, the sample volume analysed or the type of test system, the suitability of the method is to be confirmed in the presence of the test sample. During the confirmation of the suitability of the method, particularly to determine sensitivity, the test is carried out using the micro-organisms listed in Table 2.6.27.-2. Sensitivity is meant as the capacity to detect 100 CFU or less. Not more than 100 CFU of the chosen micro-organisms are inoculated into the medium in the presence of the test sample, using at least 3 replicates.
The microbial count in the micro-organism suspensions used for inoculation is determined by streaking an appropriate sample on agar plates. If between 1 and 100 CFU are detected for each strain within the duration of the assay, the method is suitable for the intended test sample.

It may be necessary to modify the list of micro-organisms in Table 2.6.27.-2 depending on the origin of the cells and any micro-organisms previously found or associated with the particular type of cells.

In some cases, the cell-based preparation itself can inactivate contaminating micro-organisms. Appropriate measures must be taken to ensure the suitability of any additional microbial strains used for confirmation of method suitability.

Table 2.6.27.-2. – *Micro-organisms used for method suitability*

Aerobic medium	
Aspergillus brasiliensis	for example, ATCC 16404, IP 1431.83, IMI 149007
Bacillus subtilis	for example, ATCC 6633, CIP 52.62, NCIMB 8054
Candida albicans	for example, ATCC 10231, IP 48.72, NCPF 3179
Pseudomonas aeruginosa	for example, ATCC 9027, NCIMB 8626, CIP 82.118
Staphylococcus aureus	for example, ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518
Streptococcus pyogenes	for example, ATCC 19615, CIP 1042.26, NCIMB 13285
Micrococcus sp.	for example, ATCC 700405
Anaerobic medium	
Clostridium sporogenes	for example, ATCC 19404, CIP 79.3, NCTC 532 or ATCC 11437
Cutibacterium acnes	for example, ATCC 11827

3-1-3 Testing of the preparation to be examined

Sample A sample that is representative of the characteristics of the cell-based preparation is tested. The sample is added to the culture medium as soon as possible. If it is necessary to store samples, the impact of the storage on potential contaminants is evaluated.

For cell-based preparations where the total volume (*V*) of the batch is between 1 mL and 1 L in a single container, the following table indicates the inoculation volume to be used.

Total cell-based preparation volume (mL)	Total inoculum volume (divided between aerobic and anaerobic bottles)
$10 \leq V \leq 1000$	1 per cent of total volume of preparation to be tested
$1 \leq V < 10$	100 µL
$V < 1$	Not applicable

For other volumes or multiple containers, alternative approaches should be used and have to be justified (see section 2-2-2). Enlargement of the total volume by means of dilution may be envisaged to assure complete inoculation of sample volumes of 100 µL. For preparation volumes less than 1 mL, where final sampling is not possible, surrogate testing, in-process testing or other appropriate testing should be used and has to be justified.

Analysis Samples are inoculated into containers of culture medium as soon as possible and incubated for not less than 7 days. Depending on the results obtained during method suitability testing and considering relevant micro-organisms, the incubation period may be extended up to 14 days. Selection of incubation temperatures should enable detection of a broad range of micro-organisms. This is typically in the range of 30-37 °C; however, for cell-based preparations with a very short shelf-life, a growth-accelerating temperature of not less than 35 °C may be more appropriate to obtain a relevant 'negative-to-date' readout of the test. In addition, for preparations where there is a significant risk of contamination from the environment, 2 temperature ranges of, for example, 20-25 °C (for aerobic) and 30-37 °C (for anaerobic) are used, in order to cover both environmental and clinical micro-organisms.

Table 2.6.27.-3 lists possible alternative approaches for the choice of incubation temperatures. The temperature and time for incubation are based on the results of the suitability study for the specific cell-based preparation.

Table 2.6.27.-3. – *Possible temperature settings in automated culturing systems used alone or in combination with manual testing*

	Aerobic incubation	Anaerobic incubation
Option 1	20-25 °C (automated system), if necessary 30-35 °C (automated system)	30-35 °C (automated system)
Option 2	35-37 °C (automated system); where relevant, additional incubation at a lower temperature (manual method)*	35-37 °C (automated system)
Option 3	30-32 °C (automated system)	30-32 °C (automated system)
Option 4	30-32 °C (automated system)	35-37 °C (automated system)

* Where relevant, incubate in addition at a temperature between 20 °C and 30 °C. Incubation can be performed using commercially available microbiological media, either aerobic bottles intended for automated systems or casein soya bean digest broth.

3-1-4 Observation and interpretation of results

Media are examined, visually or with automated systems, at least daily and at the end of the observation period for evidence of microbial growth. If no growth is observed during or at the end of the observation period, the product is 'culture negative'. If growth is observed in a valid test, the product is 'culture positive'.

If the inoculated bottles are stored for more than 12 h before being placed into the automated culturing system, a subculture of each incubated bottle is performed to check for false negatives. This addresses cases in which, where a micro-organism is fast-growing and the conditions are optimal, micro-organisms may start to proliferate during storage. As a consequence, there may not be a significant increase in the relevant parameters at the time of testing and microbial contaminants may not be recognised by the system (false negative result).

3-2 ALTERNATIVE METHODS

3-2-1 Combination of preculturing and detection by alternative methods

The samples to be tested are incubated in both aerobic and anaerobic liquid cultivation media or equivalent solid media for a short period of time (e.g. 12-24 h depending on the sensitivity of the alternative approach used). An alternative method suitable for rapid detection of micro-organisms is then performed (e.g. nucleic acid amplification techniques (*2.6.21*), flow cytometry (*2.7.24*), bioluminescence (*5.1.6*)).

3-2-2 Direct detection by alternative methods (*5.1.6*)

Where a cell-based preparation has a very short shelf-life (e.g. a few hours) or where standard methods do not provide satisfactory detection of micro-organisms, non-growth-based, direct detection methods may be carried out for microbiological examination (e.g. nucleic acid amplification techniques (*2.6.21*), flow cytometry (*2.7.24*), bioluminescence (*5.1.6*)).

This approach enables a result to be obtained within a very short time, although at the expense of lower sensitivity, in comparison to growth-based methods. Depending on the approach used, both viable and non-viable micro-organisms may be detected.

3-2-3 Method validation

Validation is carried out according to the general recommendations of general chapter *5.1.6* and according to the recommendations specific to cell-based preparations in section 3-1-2 for automated growth-based methods.

The sensitivity of these approaches must be validated considering the doubling times of potentially contaminating micro-organisms during pre-incubation.

F. Microbiological Examination of Herbal Medicinal Products for Oral Use and Extracts used in their Preparation

(Ph. Eur. method 2.6.31)

1 MICROBIAL ENUMERATION TESTS

Total aerobic microbial count (TAMC)

Perform as described in general chapter *2.6.12.*

Total combined yeasts/moulds count (TYMC)

Perform as described in general chapter *2.6.12.* Due to the natural high bioburden in the products covered by general chapter *5.1.8*, use of Sabouraud-dextrose agar containing antibiotics is suitable.

2 TEST FOR SPECIFIED MICRO-ORGANISMS

2-1 INTRODUCTION

The tests described hereafter will allow determination of the absence or limited occurrence of specified micro-organisms that may be detected under the conditions described.

The tests are designed primarily to determine whether a product, substance or preparation (hereinafter referred to as 'the product') complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2-2 GENERAL PROCEDURES

The preparation of samples is carried out as described in general chapter *2.6.12.*

If the product to be examined has antimicrobial activity, this is as far as possible removed or neutralised as described in general chapter *2.6.12.*

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated as described in general chapter *2.6.12.*

2-3 GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA, SUITABILITY OF THE TEST AND NEGATIVE CONTROLS

The ability of the test to detect micro-organisms in the presence of the product to be examined must be established. Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

2-3-1 PREPARATION OF TEST STRAINS

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed lot.

2-3-1-1 Aerobic micro-organisms

Grow each of the bacterial test strains separately in casein soya bean digest broth or on casein soya bean digest agar at 30-35 °C for 18-24 h.

- *Staphylococcus aureus* such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276;
- *Pseudomonas aeruginosa* such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275;
- *Escherichia coli* such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972;
- *Salmonella enterica* subsp. *enterica* serovar Typhimurium such as ATCC 14028 or, as an alternative, *S. enterica* subsp. *enterica* serovar Abony such as NBRC 100797, NCTC 6017 or CIP 80.39;
- *Bacillus subtilis* such as ATCC 6633, NCIMB 8054, CIP 52.62 or NBRC 3134.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions. Use the suspensions within 2 h, or within 24 h if stored at 2-8 °C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period of time.

2-3-2 NEGATIVE CONTROL

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described in section 2-4. A failed negative control requires an investigation.

2-3-3 GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from the ingredients described.

Verify suitable properties of relevant media as described in Table 2.6.31.-1.

Test for growth-promoting properties, liquid media

Inoculate a portion of the appropriate medium with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Incubate the casein soya bean digest broth at 30-35 °C for not more than 3 days. Clearly visible growth of the micro-organism comparable to that obtained with a previously tested and approved batch of medium occurs.

Test for growth-promoting properties, solid media

Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism comparable to that obtained with a previously tested and approved batch of medium occurs.

Test for inhibitory properties, liquid or solid media

Inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test micro-organism occurs.

Test for indicative properties

Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those obtained with a previously tested and approved batch of medium.

2-3-4 SUITABILITY OF THE TEST METHOD

For each product to be examined, perform the sample preparation as described in the relevant paragraph in section 2-4. Add each test strain at the time of mixing, in the prescribed growth medium (casein soya bean digest broth or

Table 2.6.31.-1. – *Growth-promoting, inhibitory and indicative properties of media*

	Medium	Property	Test strains
Test for bile-tolerant gram-negative bacteria	Casein soya bean digest broth	Growth promoting	*S. aureus* *P. aeruginosa* *B. subtilis*
	Enterobacteria enrichment broth-Mossel	Growth promoting	*E. coli* *P. aeruginosa*
		Inhibitory	*S. aureus*
	Violet red bile glucose agar	Growth promoting + indicative	*E. coli* *P. aeruginosa*
Test for *Escherichia coli*	Casein soya bean digest broth	Growth promoting	*S. aureus* *P. aeruginosa* *B. subtilis*
	MacConkey broth	Growth promoting	*E. coli*
		Inhibitory	*S. aureus*
	MacConkey agar	Growth promoting + indicative	*E. coli*
Test for *Salmonella*	Buffered peptone medium	Growth promoting	*S. enterica* subsp. *enterica* serovar Typhimurium or *S. enterica* subsp. *enterica* serovar Abony
	Rappaport Vassiliadis *Salmonella* enrichment broth	Growth promoting	*S. enterica* subsp. *enterica* serovar Typhimurium or *S. enterica* subsp. *enterica* serovar Abony
		Inhibitory	*S. aureus*
	Xylose, lysine, deoxycholate agar	Growth promoting + indicative	*S. enterica* subsp. *enterica* serovar Typhimurium or *S. enterica* subsp. *enterica* serovar Abony

buffered peptone medium). For the enumeration method for bile-tolerant gram-negative bacteria, inoculate *E. coli* and *P. aeruginosa* individually. For the tests for *E. coli* and *Salmonella*, inoculate the specified micro-organism individually.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see section 4-5-3 of general chapter *2.6.12*).

If for a given product the antimicrobial activity with respect to a micro-organism for which testing is prescribed cannot be neutralised, then it is to be assumed that the inhibited micro-organism will not be present in the product.

2-3-4-1 Test for absence

Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation. Perform the test as described in the relevant paragraph in section 2-4 using the shortest incubation period prescribed. The specified micro-organisms must be detected with the indication reactions as described in section 2-4.

2-3-4-2 Enumeration test

Semi-quantitative test (probable-number method).

Use a number of micro-organisms equivalent to not more than 100 CFU per gram or millilitre of product. Perform the test as described in the relevant paragraph in section 2-4 using the shortest incubation period prescribed. The dilution corresponding to 0.1 g or 0.1 mL of product must be positive.

2-4 TESTING OF PRODUCTS

2-4-1 BILE-TOLERANT GRAM-NEGATIVE BACTERIA

2-4-1-1 Enumeration test

Semi-quantitative test (probable-number method).

2-4-1-1-1 Sample preparation and pre-incubation. Prepare a sample using a 10-fold dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, but using casein soya bean digest broth as the chosen diluent, mix and incubate at 20-25 °C for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the organisms (2-3 h).

2-4-1-1-2 Selection and subculture. Inoculate suitable quantities of enterobacteria enrichment broth-Mossel with the preparation as described above and/or, depending on the limit applied for the particular product, with 3 of the 4 dilutions of the preparation, which contain respectively 0.1 g, 0.01 g, 0.001 g and 0.0001 g (or 0.1 mL, 0.01 mL, 0.001 mL and 0.0001 mL) of the product to be examined. Incubate at 30-35 °C for 24-48 h. Subculture each of the cultures on a plate of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

2-4-1-1-3 Interpretation. Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result.

Determine from Table 2.6.31.-2 the probable number of bacteria.

Table 2.6.31.-2. – *Interpretation of results*

Results for each quantity of product				Probable number of bacteria per gram or millilitre of product
0.1 g or 0.1 mL	0.01 g or 0.01 mL	0.001 g or 0.001 mL	0.0001 g or 0.0001 mL	
+	+	+	+	$> 10^4$
+	+	+	-	$< 10^4$ and $> 10^3$
+	+	-	-	$< 10^3$ and $> 10^2$
+	-	-	-	$< 10^2$ and > 10
-	-	-	-	< 10

2-4-2 ESCHERICHIA COLI

2-4-2-1 Test for absence

2-4-2-1-1 Sample preparation and pre-incubation. Prepare a sample using a 10-fold dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described in section 2-3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

2-4-2-1-2 Selection and subculture. Shake the container, transfer 1 mL of casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h.

Subculture on a plate of MacConkey agar at 30-35 °C for 18-72 h.

2-4-2-1-3 Interpretation. Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The product complies with the test if no colonies are present or if the identification tests are negative.

2-4-2-2 Enumeration test

Semi-quantitative test (probable-number method).

2-4-2-2-1 Sample preparation and pre-incubation. Prepare a sample using a 10-fold dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use the quantities corresponding respectively to 0.1 g, 0.01 g and 0.001 g (or 0.1 mL, 0.01 mL and 0.001 mL) to inoculate a suitable amount (determined as described in section 2-3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

2-4-2-2-2 Selection and subculture. Shake the container, transfer 1 mL of casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on a plate of MacConkey agar at 30-35 °C for 18-72 h.

2-4-2-2-3 Interpretation. Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result.

Determine from Table 2.6.31.-3 the probable number of bacteria.

Table 2.6.31.-3. – *Interpretation of results*

Results for each quantity of product			Probable number of bacteria per gram or millilitre of product
0.1 g or 0.1 mL	0.01 g or 0.01 mL	0.001 g or 0.001 mL	
+	+	+	$> 10^3$
+	+	-	$< 10^3$ and $> 10^2$
+	-	-	$< 10^2$ and > 10
-	-	-	< 10

2-4-3 SALMONELLA

2-4-3-1 Test for absence

2-4-3-1-1 Sample preparation and pre-incubation. Use 25 g or 25 mL of the product to be examined to inoculate 225 mL of buffered peptone medium and mix (e.g. homogenise in a filter bag by using a blender). Incubate at 30-35 °C for 18-24 h.

2-4-3-1-2 Selection and subculture. Transfer 0.1 mL of buffered peptone medium to 10 mL of Rappaport Vassiliadis *Salmonella* enrichment broth and incubate at 30-35 °C for 18-24 h. Subculture on plates of xylose, lysine and deoxycholate agar. Incubate at 30-35 °C for 18-48 h.

2-4-3-1-3 Interpretation. The possible presence of *Salmonella* is indicated by the growth of well-developed, red colonies, with or without black centres. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the identification tests are negative.

The following section is given for information.

RECOMMENDED SOLUTIONS AND CULTURE MEDIA

The solutions and culture media mentioned in this chapter and described in general chapter *2.6.13* and the following buffered peptone medium have been found to be satisfactory for the purposes for which they are prescribed in this chapter. Other media may be used provided that their suitability can be demonstrated.

Buffered peptone medium

Potassium dihydrogen phosphate	1.5 g
Disodium hydrogen phosphate dodecahydrate	9.0 g
Sodium chloride	5.0 g
Peptone	10.0 g
Purified water	1000 mL

Adjust the pH so that after sterilisation it is 7.0 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

G. Microbiological Quality of Herbal Medicinal Products for Oral Use and Extracts Used in their Preparation

(Ph. Eur. general texts 5.1.8)

This general chapter presents recommended acceptance criteria for the microbiological quality of both herbal medicinal products for oral use and the extracts that are used in their preparation.

Microbial examination of non-sterile products is performed according to the methods given in general chapters *2.6.12*, *2.6.13* and *2.6.31*. Acceptance criteria based upon the total aerobic microbial count (TAMC) and the total combined yeasts/moulds count (TYMC) are given below.

Acceptance criteria are based on individual results or on the average of replicate counts when replicate counts are performed (e.g. direct plating methods).

A list of specified micro-organisms for which acceptance criteria are set can be found below. The list is not necessarily exhaustive and for a given preparation it may be necessary to test for other micro-organisms depending on the nature of the starting materials, the manufacturing process and the intended use.

Medicinal products containing live yeasts (live biotherapeutic products) are not within the scope of this general chapter.

HERBAL MEDICINAL PRODUCTS

A. Herbal medicinal products containing herbal drugs, with or without excipients, intended for the preparation of infusions and decoctions using boiling water (for example herbal teas, with or without added flavourings)

TAMC (*2.6.12*)	Acceptance criterion: 10^7 CFU/g Maximum acceptable count: 50 000 000 CFU/g
TYMC (*2.6.12*)	Acceptance criterion: 10^5 CFU/g Maximum acceptable count: 500 000 CFU/g
Escherichia coli (*2.6.31*)	Acceptance criterion: 10^3 CFU/g
Salmonella (*2.6.31*)	Absence (25 g)

B. Herbal medicinal products containing, for example, extracts and/or herbal drugs, with or without excipients, where the method of processing (for example, extraction) or, where appropriate, in the case of herbal drugs, of pre-treatment reduces the levels of organisms to below those stated for this category

TAMC (*2.6.12*)	Acceptance criterion: 10^4 CFU/g or CFU/mL Maximum acceptable count: 50 000 CFU/g or CFU/mL
TYMC (*2.6.12*)	Acceptance criterion: 10^2 CFU/g or CFU/mL Maximum acceptable count: 500 CFU/g or CFU/mL
Bile-tolerant gram-negative bacteria (*2.6.31*)	Acceptance criterion: 10^2 CFU/g or CFU/mL
Escherichia coli (*2.6.31*)	Absence (1 g or 1 mL)
Salmonella (*2.6.31*)	Absence (25 g or 25 mL)

C. Herbal medicinal products containing, for example, extracts and/or herbal drugs, with or without excipients, where it can be demonstrated that the method of processing (for example, extraction with low-strength ethanol or water that is not boiling, or low-temperature concentration) or, in the case of herbal drugs, of pre-treatment, would not reduce the level of organisms sufficiently to reach the criteria required under B

TAMC (*2.6.12*)	Acceptance criterion: 10^5 CFU/g or CFU/mL Maximum acceptable count: 500 000 CFU/g or CFU/mL
TYMC (*2.6.12*)	Acceptance criterion: 10^4 CFU/g or CFU/mL Maximum acceptable count: 50 000 CFU/g or CFU/mL
Bile-tolerant gram-negative bacteria (*2.6.31*)	Acceptance criterion: 10^4 CFU/g or CFU/mL
Escherichia coli (*2.6.31*)	Absence (1 g or 1 mL)
Salmonella (*2.6.31*)	Absence (25 g or 25 mL)

EXTRACTS

Extracts should fulfill the acceptance criteria for category B herbal medicinal products. However, where it can be demonstrated that the method of processing would not reduce the level of micro-organisms sufficiently to reach the category B criteria, the extracts shall meet the requirements for category C herbal medicinal products.

The recommended acceptance criteria apply to extracts that are to be incorporated into herbal medicinal products for oral use. More-stringent acceptance criteria may be required for extracts that are to be incorporated into pharmaceutical preparations to be administered by other routes in order to satisfy the acceptance criteria for the intended route of administration (*5.1.4*).

It is recognised that for some herbal medicinal products and extracts used in their preparation the criteria given above for TAMC, TYMC and bile-tolerant gram-negative bacteria cannot be met because of the typical level of microbial contamination. Less-stringent acceptance criteria may be applied on the basis of a risk assessment that takes account of qualitative and quantitative characterisation of the microbial contamination and the intended use of the herbal medicinal product or extract.

If it has been shown that none of the prescribed tests for a herbal medicinal product or extract will allow valid enumeration of micro-organisms at the level prescribed, a validated method with a limit of detection as close as possible to the indicated acceptance criterion is used.

H. Microbiological Examination of Live Biotherapeutic Products

Microbiological Examination of Live Biotherapeutic Products: Tests for Enumeration of Microbial Contaminants

(Ph. Eur. method 2.6.36)

1. INTRODUCTION

The tests described hereafter will allow enumeration of live biotherapeutic product (LBP) contaminants: mesophilic bacteria and yeasts/moulds that may grow under aerobic conditions.

The tests are designed primarily to determine whether an LBP substance or preparation complies with the established specifications for microbial contamination.

Alternative microbiological procedures (*5.1.6*), including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2. GENERAL PROCEDURES

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the LBP to be tested. The precautions taken to avoid contamination must be such that they do not affect any contaminant micro-organisms that are to be revealed in the test.

If the LBP to be tested prevents the enumeration of contaminant micro-organisms, apply the decision tree shown in Figure 2.6.36.-1.

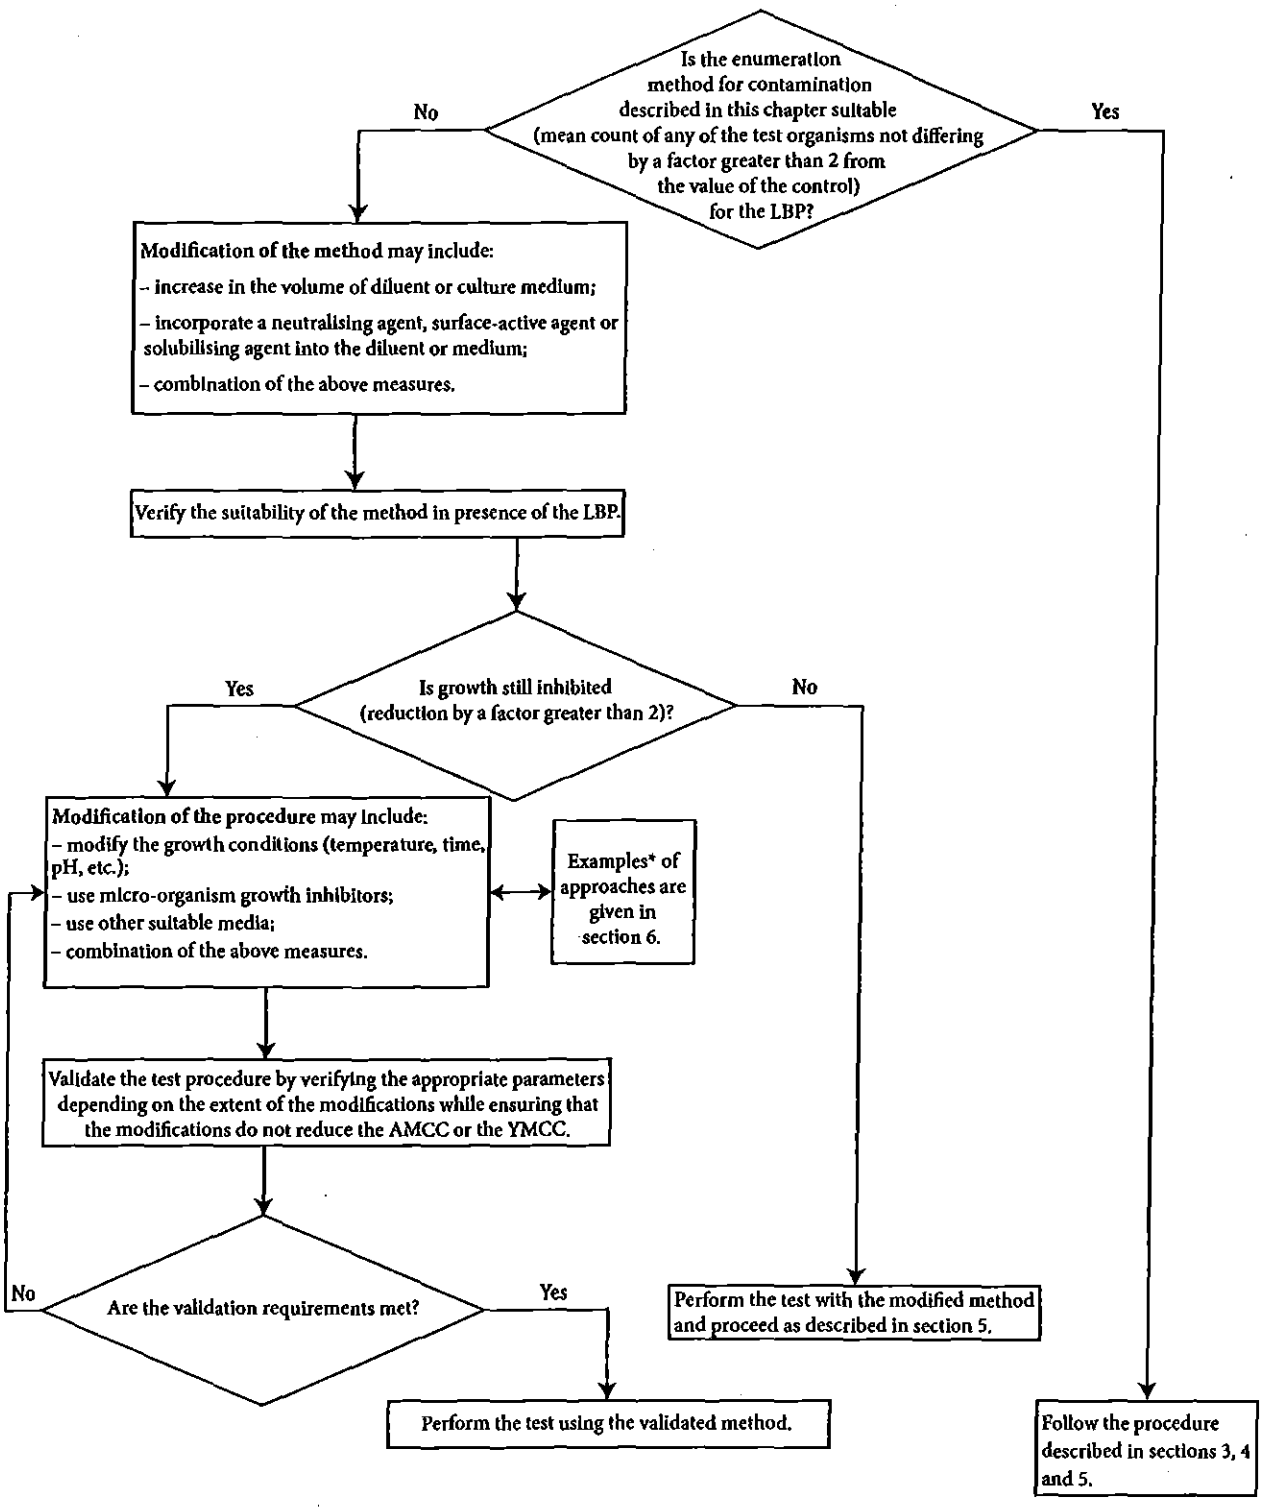
If components other than the active substance (i.e. the micro-organism) of the LBP to be tested have inhibitory activity, this is insofar as possible removed or neutralised as described in general chapter *2.6.12*. If inactivators are used for this purpose, their efficacy and their absence of toxicity for the target contaminant micro-organisms must be demonstrated.

If surface-active substances are used for sample preparation, their absence of toxicity for the target contaminant micro-organisms and their compatibility with inactivators used must be demonstrated.

3. ENUMERATION METHODS

Use the plate-count or the most-probable-number (MPN) method. The MPN method is generally the least accurate method for microbial counts.

The choice of method is based on factors such as the nature of the LBP and the required limit of microbial contamination. The chosen method must allow testing of a sufficient sample size to judge compliance with the specification. The suitability of the method chosen must be established.



* This section should be understood as informative suggestion. Other procedures are possible as far as they are justified.

Figure 2.6.36.-1. – *Decision tree for the microbial contamination enumeration methods*

4. GROWTH PROMOTION TEST, SUITABILITY OF THE COUNTING METHOD AND NEGATIVE CONTROLS

4-1. GENERAL CONSIDERATIONS

The ability of the test to detect microbial contamination in the presence of the LBP to be tested must be established.

Suitability must be confirmed if a change in testing performance, or in the LBP, which may affect the outcome of the test is introduced.

4-2. PREPARATION OF TEST STRAINS

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in Table 2.6.36.-1.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions; to suspend *A. brasiliensis* spores, 0.05 per cent of polysorbate 80 may be added to the buffer. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *A. brasiliensis* or *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period of time.

4-3. NEGATIVE CONTROL

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the LBP as described in section 5. A failed negative control requires an investigation.

4-4. GROWTH PROMOTION OF THE MEDIA

Test each batch of ready-prepared medium and each batch of medium, prepared either from dehydrated medium or from the ingredients described.

Inoculate portions/plates of casein soya bean digest broth and casein soya bean digest agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.36.-1, using a separate portion/plate of medium for each. Inoculate plates of Sabouraud-dextrose agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.36.-1, using a separate plate of medium for each. Incubate in the conditions described in Table 2.6.36.-1.

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardised inoculum. For a freshly prepared inoculum, growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs. Liquid media are suitable if clearly visible growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

4-5. SUITABILITY OF THE COUNTING METHOD IN THE PRESENCE OF THE LBP TO BE TESTED

4-5-1. Preparation of the sample

The method for sample preparation depends upon the physical characteristics of the LBP to be tested. If none of the procedures described below can be demonstrated to be satisfactory, an alternative procedure must be developed.

Prepare a homogenous suspension of the LBP to be tested (usually a 1 in 10 dilution is prepared) in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. A surface-active agent such as a 1 g/L solution of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

4-5-2. Inoculation and dilution

Add to the sample prepared as described above (4-5-1) and to a control (with no test material included) a sufficient volume of the microbial suspension to obtain an inoculum of not more than 100 CFU. The volume of the suspension of the inoculum should not exceed 1 per cent of the volume of diluted LBP.

To demonstrate acceptable recovery of the test micro-organisms from the LBP, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to inhibitory activity of the LBP, further appropriate protocols must be developed (see decision tree shown in Figure 2.6.36.-1). If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the test micro-organisms may be added after neutralisation or dilution.

Inhibitory activity The number of micro-organisms recovered from the prepared sample diluted as described in 4-5-2 and incubated following the procedure described in 4-5-3, is compared to the number of micro-organisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), follow the decision tree shown in Figure 2.6.36.-1 and modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example, (1) an increase in the volume of the diluent or culture medium, (2) incorporation of specific or general neutralising agents into the diluent, (3) membrane filtration, or (4) a combination of the above measures.

If growth is still inhibited (reduction by a factor greater than 2) continue to follow the decision tree shown in Figure 2.6.36.-1.

A new approach needs to be validated using the appropriate parameters depending on the extent of modification, while ensuring that the modifications do not reduce the AMCC or the YMCC.

4-5-3. Recovery of the test micro-organisms in the presence of an LBP

For each of the test micro-organisms listed, separate tests are performed. Only micro-organisms of the added test strain are counted.

4-5-3-1. Plate-count methods Perform plate-count methods at least in duplicate for each medium and use the mean count of the result.

4-5-3-1-1. Pour-plate method

For Petri dishes 9 cm in diameter, add to the dish 1 mL of the sample prepared as described under 4-5-1 and 4-5-2, and 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar, both media being at not more than 45 °C. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the micro-organisms listed in Table 2.6.36.-1, at least 2 Petri dishes are used. Incubate the plates as indicated in Table 2.6.36.-1. Take the arithmetic mean of the counts per medium and calculate the number of CFU in the original inoculum.

4-5-3-1-2. Surface-spread method

For Petri dishes 9 cm in diameter, add 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar at about 45 °C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a laminar-air-flow cabinet or an incubator. For each of the micro-organisms listed in Table 2.6.36.-1, at least 2 Petri dishes are used. Spread a measured volume of not less than 0.1 mL of the sample prepared as described under 4-5-1 and 4-5-2 over the surface of the medium. Incubate and count as prescribed under 4-5-3-1-1.

4-5-3-2. Most-probable-number (MPN) method The precision and accuracy of the MPN method is less than the plate-count method. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of AMCC

Table 2.6.36.-1. – *Preparation and use of test micro-organisms*

Micro-organism	Preparation of test strain	Growth promotion		Suitability of counting method in the presence of the LBP	
		Aerobic microbial contamination count (AMCC)	Yeasts and moulds contamination count (YMCC)	Aerobic microbial contamination count (AMCC)	Yeasts and moulds contamination count (YMCC)
Staphylococcus aureus such as: ATCC 6538 NCIMB 9518 CIP 4.83 NBRC 13276	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN: casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Pseudomonas aeruginosa such as: ATCC 9027 NCIMB 8626 CIP 82.118 NBRC 13275	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN: casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Bacillus subtilis such as: ATCC 6633 NCIMB 8054 CIP 52.62 NBRC 3134	Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h	Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-	Casein soya bean digest agar/MPN: casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days	-
Candida albicans such as: ATCC 10231 NCPF 3179 IP 48.72 NBRC 1594	Sabouraud- dextrose agar or Sabouraud-dextrose broth 20-25 °C 2-3 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days	Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable	Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days
Aspergillus brasiliensis such as: ATCC 16404 IMI 149007 IP 1431.83 NBRC 9455	Sabouraud- dextrose agar or potato-dextrose agar 20-25 °C 5-7 days, or until good sporulation is achieved	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days	Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days	Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable	Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days

in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least 3 serial tenfold dilutions of the LBP as described under 4-5-1 and 4-5-2. From each level of dilution, 3 aliquots of 1 g or 1 mL are used to inoculate 3 tubes with 9-10 mL of casein soya bean digest broth. If necessary, a surface-active agent such as polysorbate 80 may be added to the medium. Thus, if 3 levels of dilution are prepared, 9 tubes are inoculated.

Incubate all tubes at 30-35 °C for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the LBP to be tested, subculture in the same broth, or in casein soya bean digest agar, for 1-2 days at the same temperature and use these results. Determine the most probable number of micro-organisms per gram or millilitre of the LBP to be tested from Table 2.6.36.-2.

4-6. RESULTS AND INTERPRETATION

When verifying the suitability of the plate-count method, a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in 4-5-2 in the absence of the LBP must be obtained. When verifying the suitability of the MPN method the calculated value from the inoculum must be within 95 per cent confidence limits of the results obtained with the control.

If the above criteria cannot be met, follow the decision tree shown in Figure 2.6.36.-1 and modify the procedure for the particular enumeration test to ensure the validity of the results.

5. TESTING OF LIVE BIOTHERAPEUTIC PRODUCTS

5-1. AMOUNT USED FOR THE TEST

Unless otherwise prescribed, use 10 g or 10 mL of the LBP to be tested taken with the precautions referred to above.

For LBP where the total number of entities in a batch is less than 200 (e.g. samples used in clinical trials), the sample size may be reduced to 2 units, or 1 unit if the size is less than 100.

Select the sample(s) at random from the bulk material or from the available containers of the preparation. To obtain the required quantity, mix the contents of a sufficient number of containers to provide the sample.

Table 2.6.36.-2. – *Most-probable-number values of micro-organisms*

Observed combinations of numbers of tubes showing growth in each set			MPN per gram or per millilitre of LBP	95 per cent confidence limits
Number of grams or millilitres of LBP per tube				
0.1	0.01	0.001		
0	0	0	< 3	0 - 9.4
0	0	1	3	0.1 - 9.5
0	1	0	3	0.1 - 10
0	1	1	6.1	1.2 - 17
0	2	0	6.2	1.2 - 17

Observed combinations of numbers of tubes showing growth in each set			MPN per gram or per millilitre of LBP	95 per cent confidence limits
Number of grams or millilitres of LBP per tube				
0.1	0.01	0.001		
0	3	0	9.4	3.5 - 35
1	0	0	3.6	0.2 - 17
1	0	1	7.2	1.2 - 17
1	0	2	11	4 - 35
1	1	0	7.4	1.3 - 20
1	1	1	11	4 - 35
1	2	0	11	4 - 35
1	2	1	15	5 - 38

3	3	0	240	40 - 990
3	3	1	460	90 - 1980
3	3	2	1100	200 - 4000
3	3	3	> 1100	

5-2. EXAMINATION OF THE LBP

5-2-1. Plate-count methods

5-2-1-1. Pour-plate method Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare for each medium at least 2 Petri dishes for each level of dilution. Incubate the plates of casein soya bean digest agar at 30-35 °C for 3-5 days and the plates of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Select the plates corresponding to a given dilution and showing the highest number of contaminating colonies less than 250 for AMCC and 50 for YMCC. Take the arithmetic mean per culture medium of the counts and calculate the number of CFU per gram or per millilitre of LBP.

5-2-1-2. Surface-spread method Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare at least 2 Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of contaminant CFU proceed as described for the pour-plate method.

5-2-2. Most-probable-number method

Prepare and dilute the sample using a method that has been shown to be suitable as described in section 4. Incubate all tubes at 30-35 °C for 3-5 days. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of contaminant micro-organisms per gram or millilitre of the LBP to be tested from Table 2.6.36.-2.

5-3. INTERPRETATION OF THE RESULTS

The aerobic microbial contamination count (AMCC) is considered to be equal to the number of contaminating CFU found using casein soya bean digest agar; if colonies of contaminating yeasts/moulds are detected on this medium, they are counted as part of the AMCC. The combined yeasts/moulds contaminants count (YMCC) is considered to be equal to the number of CFU found using Sabouraud-dextrose agar; if colonies of contaminating bacteria are detected on this medium, they may be excluded from the YMCC. When the YMCC is expected to exceed the acceptance criterion due to bacterial growth, Sabouraud-dextrose agar containing antibiotics can be used (see decision tree shown in Figure 2.6.36.-1). If the count is carried out by the MPN method the calculated value is the AMCC.

When an acceptance criterion for microbial contamination is prescribed it is interpreted as follows:

— 10^1 CFU: maximum acceptable count = 20;
— 10^2 CFU: maximum acceptable count = 200;
— 10^3 CFU: maximum acceptable count = 2000.

The recommended solutions and media are described in general chapter *2.6.13.*

6. APPROACHES FOR ENUMERATION OF MICROBIAL CONTAMINANTS IN THE PRESENCE OF INHIBITION DUE TO THE LBP

This section should be understood as informative suggestion. Other procedures are possible as far as they are justified. Examples of approaches for enumeration of microbial contaminants for LBP inhibiting the microbial contamination enumeration are indicated below.

Each approach needs to be validated using the appropriate parameters depending on the extent of modification, while ensuring that the modifications do not reduce the AMCC or the YMCC.

The test strains indicated in Table 2.6.36.-1 are used. Preparation of test strains is performed as described in 4-2. Negative control is performed as described in 4-3. Growth promotion and suitability of new culture media chosen is carried out by inoculating each batch of the medium with a small number (not more than 100 CFU) of the micro-organisms. Growth obtained does not differ by a factor greater than 2 from the calculated value for a standardised

inoculum counted on casein soya bean digest agar (AMCC) or Sabouraud-dextrose agar (YMCC).

6-1. ENUMERATION OF AEROBIC MICROBIAL CONTAMINANTS

LBP containing lactic acid bacteria may be tested for aerobic microbial contamination on sugar-free agar plates incubated aerobically at 30-35 °C for 72 h. Lactic acid bacteria grow slowly as pinpoint colonies, while contaminants can easily be detected as larger colonies and are fast growing.

Alternatively, the aerobic microbial contamination may be tested on casein soya bean digest agar plates supplemented with 5 per cent of sheep blood at 30-35 °C for 44-48 h. The addition of blood enhances growth of contaminants and formation of distinctive colony morphology that are better discriminated in the presence of lactic acid bacteria.

For LBP containing *Bacillus clausii* spores, the aerobic microbial contamination may be enumerated on sporulating agar. The medium, by promoting the sporulation of *Bacillus clausii*, inhibits the vegetative growth of the LBP micro-organism, making the detection of contaminants possible. Plates are incubated at 33-37 °C for 48 h.

LBP containing *Saccharomyces cerevisiae*, var. *boulardii* may be tested for aerobic microbial contamination on casein soya bean digest agar containing cycloheximide, a suitable inhibitor of *Saccharomyces*. Plates are incubated at 30-35 °C for 3-5 days.

For LBP for which suitable media and growth conditions to enumerate aerobic microbial contamination are not available, not only the absence of specific contaminants (*Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Salmonella* spp. and bile-tolerant Gram-negative bacteria) is verified using the method described in general chapter *2.6.38*, and tests for other contaminating micro-organisms are carried out based on a risk assessment (e.g. specific environmental contaminants).

6-2. ENUMERATION OF YEAST AND MOULD CONTAMINANTS

For LBP containing bacteria, the test may be carried out with Sabouraud-dextrose agar containing antimicrobials (e.g. chloramphenicol) incubated at 20-25 °C for 5-7 days.

For LBP containing *Saccharomyces cerevisae*, var. *boulardii*, yeasts and moulds may be determined using several media (Sabouraud-dextrose agar supplemented with chloramphenicol and cycloheximide, Czapek-Dox agar, potato dextrose agar).

Microbiological Examination of Live Biotherapeutic Products: Tests for Specified Micro-organisms

(Ph. Eur. method 2.6.38)

1. INTRODUCTION

The tests described hereafter are intended for determination of the absence or limited occurrence of specified micro-organisms that may be detected under the conditions described. The tests are designed primarily to determine whether a live biotherapeutic product (LBP) complies with the established specification for microbiological quality.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2. GENERAL PROCEDURES

The preparation of samples is carried out as described in general chapter *2.6.36*.

If the LBP to be tested prevents the detection of specified micro-organisms apply the decision tree shown in Figure 2.6.38.-1.

If components other than the active substance (i.e. the micro-organism) of the LBP to be tested have inhibitory activity against the target contaminant micro-organisms, this is insofar as possible removed or neutralised as described in general chapter *2.6.36*.

If surface-active agents are used for sample preparation, their absence of toxicity for the target contaminant micro-organisms and their compatibility with inactivators used must be demonstrated as described in general chapter *2.6.36*.

3. GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA, SUITABILITY OF THE TEST AND NEGATIVE CONTROLS

The ability of the test to detect the target micro-organisms in the presence of the LBP to be tested must be established. Suitability must be confirmed if a change is introduced in the testing procedure or the LBP, which may affect the outcome of the test.

3-1. PREPARATION OF TEST STRAINS

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

3-1-1. Aerobic micro-organisms

Grow each of the bacterial test strains separately in casein soya bean digest broth or on casein soya bean digest agar at 30-35 °C for 18-24 h. Grow the test strain for *Candida albicans* separately on Sabouraud-dextrose agar or in Sabouraud-dextrose broth at 20-25 °C for 2-3 days.

- *Staphylococcus aureus* such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276;
- *Pseudomonas aeruginosa* such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275;
- *Escherichia coli* such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972;
- *Salmonella enterica* subsp. *enterica* serovar Typhimurium, such as ATCC 14028 or, as an alternative, *Salmonella enterica* subsp. *enterica* serovar Abony such as NBRC 100797, NCTC 6017 or CIP 80.39;
- *Candida albicans* such as ATCC 10231, NCPF 3179, IP 48.72 or NBRC 1594.

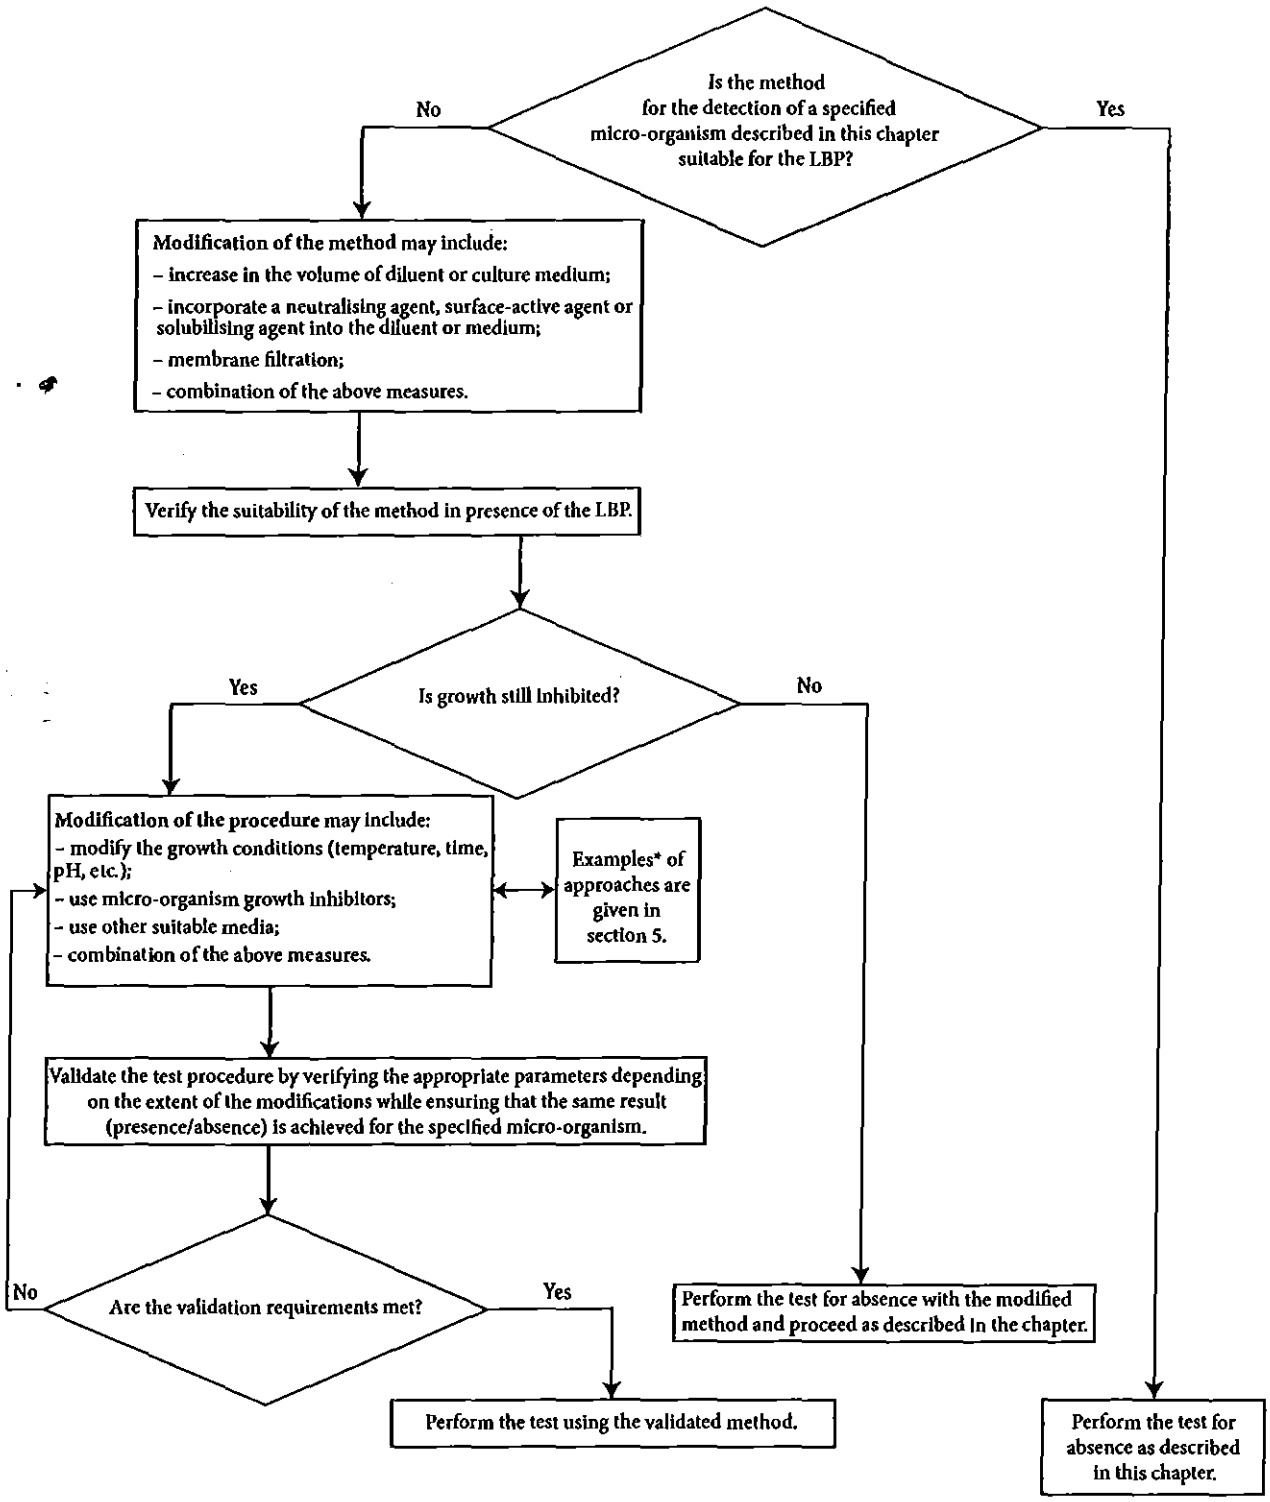
Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C.

3-1-2. Anaerobic micro-organisms

Clostridia. Use a *Clostridium sporogenes* strain such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.03) or NBRC 14293. Grow the clostridial test strain under anaerobic conditions in reinforced medium for Clostridia at 30-35 °C for 24-48 h. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of *C. sporogenes*, a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period.

3-2. NEGATIVE CONTROL

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the LBP as described in section 4. A failed negative control requires an investigation.



* This section should be understood as informative suggestion. Other procedures are possible as far as they are justified.

Figure 2.6.38.-1. – *Decision tree for the test for specified micro-organisms*

3-3. GROWTH PROMOTION AND INHIBITORY PROPERTIES OF THE MEDIA

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients.

Verify suitable properties of relevant media as described in Table 2.6.38.-1.

3-3-1. Test for growth promoting properties, liquid media

Inoculate a portion of the appropriate medium of the same volume to be used in the test (see sections 3-4 and 4) with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Clearly visible growth of the micro-organism comparable to

that previously obtained with a previously tested and approved batch of medium occurs.

3-3-2. Test for growth promoting properties, solid media

Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism is comparable to that previously obtained with a previously tested and approved batch of medium and does not differ by a factor greater than 2.

3-3-3. Test for inhibitory properties, liquid or solid media

Inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test micro-organism occurs.

3-3-4. Test for indicative properties

Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest validated period of time specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

3-4. SUITABILITY OF THE TEST METHOD

For each LBP to be tested, perform the sample preparation as described in the relevant paragraph in section 4. Inoculate the test strains individually. Add each test strain at the time of mixing, in the prescribed growth medium. Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation. The inoculum should not exceed 1 per cent of the volume of the growth medium. Perform the test as described in the relevant paragraph in section 4 using for each step of the test the shortest incubation time to be used in the test.

The specified micro-organisms must be detected with the appearance and indication reactions described in section 4. If non-characteristic colonies and reactions are obtained, the method may still be suitable provided that all colony types are identified when performing the test.

Any inhibitory activity of the LBP against the target micro-organisms necessitates a modification of the test procedure (see decision tree shown in Figure 2.6.38.-1) and then the suitability for the LBP must be confirmed.

4. TESTING OF LIVE BIOTHERAPEUTIC PRODUCTS

4-1. BILE-TOLERANT GRAM-NEGATIVE BACTERIA

4-1-1. Sample preparation and pre-incubation

Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36*, but using casein soya bean digest broth as the chosen diluent, mix and incubate at 20-25 °C for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the micro-organisms (usually 2 h but not more than 5 h).

4-1-2. Test for absence

Unless otherwise prescribed, use the volume corresponding to 1 g of the LBP, as prepared in 4-1-1, to inoculate enterobacteria enrichment broth-Mossel. Incubate at 30-35 °C for 24-48 h. Subculture on violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

Table 2.6.38.-1. – *Growth promoting, inhibitory and indicative properties of media*

	Medium	Property	Test strains
Test for bile-tolerant Gram-negative bacteria	Enterobacteria enrichment broth-Mossel	Growth promoting	*E. coli* *P. aeruginosa*
		Inhibitory	*S. aureus*
	Violet red bile glucose agar	Growth promoting + indicative	*E. coli* *P. aeruginosa*
Test for *Escherichia coli*	MacConkey broth	Growth promoting	*E. coli*
		Inhibitory	*S. aureus*
	MacConkey agar	Growth promoting + indicative	*E. coli*
Test for *Salmonella*	Rappaport Vassiliadis *Salmonella* enrichment broth	Growth promoting	*Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony
		Inhibitory	*S. aureus*
	Xylose, lysine, deoxycholate agar	Growth promoting + indicative	*Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony
Test for *Pseudomonas aeruginosa*	Cetrimide agar	Growth promoting	*P. aeruginosa*
		Inhibitory	*E. coli*
Test for *Staphylococcus aureus*	Mannitol salt agar	Growth promoting + indicative	*S. aureus*
		Inhibitory	*E. coli*
Test for Clostridia	Reinforced medium for Clostridia	Growth promoting	*C. sporogenes*
	Columbia agar	Growth promoting	*C. sporogenes*
Test for *Candida albicans*	Sabouraud-dextrose broth	Growth promoting	*C. albicans*
	Sabouraud-dextrose agar	Growth promoting + indicative	*C. albicans*

The LBP complies with the test if there is no growth of colonies.

4-2. ESCHERICHIA COLI

4-2-1. Sample preparation and pre-enrichment

Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as

described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

4-2-2. Selection and subculture
Shake the container, transfer 1 mL of the casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on MacConkey agar at 30-35 °C for 18-72 h.

4-2-3. Interpretation
Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The LBP complies with the test if colonies are not present or if the confirmatory identification tests are negative.

4-3. SALMONELLA

4-3-1. Sample preparation and pre-enrichment
Prepare the LBP to be tested as described in general chapter *2.6.36* and use the quantity corresponding to not less than 10 g or 10 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

4-3-2. Selection and subculture
Transfer 0.1 mL of the casein soya bean digest broth to 10 mL of Rappaport Vassiliadis *Salmonella* enrichment broth and incubate at 30-35 °C for 18-24 h. Subculture on xylose, lysine, deoxycholate agar. Incubate at 30-35 °C for 18-48 h.

4-3-3. Interpretation
Growth of well-developed, red colonies, with or without black centres indicates the possible presence of *Salmonella*. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-4. PSEUDOMONAS AERUGINOSA

4-4-1. Sample preparation and pre-enrichment
Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. Incubate at 30-35 °C for 18-24 h.

4-4-2. Selection and subculture
Subculture on cetrimide agar and incubate at 30-35 °C for 18-72 h.

4-4-3. Interpretation
Growth of colonies indicates the possible presence of *P. aeruginosa*. This is confirmed by identification tests.

The LBP complies with the test if colonies are not present or if the confirmatory identification tests are negative.

4-5. STAPHYLOCOCCUS AUREUS

4-5-1. Sample preparation and pre-enrichment
Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. Incubate at 30-35 °C for 18-24 h.

4-5-2. Selection and subculture
Subculture on mannitol salt agar and incubate at 30-35 °C for 18-72 h.

4-5-3. Interpretation
Growth of yellow/white colonies surrounded by a yellow zone indicates the possible presence of *S. aureus*. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-6. CLOSTRIDIA

4-6-1. Sample preparation and heat treatment
Prepare a sample using a 1 in 10 dilution (with a minimum total volume of 20 mL) of not less than 2 g or 2 mL of the LBP to be tested as described in general chapter *2.6.36*. Divide the sample into 2 portions of at least 10 mL. Heat 1 portion at 80 °C for 10 min and cool rapidly. Do not heat the other portion.

4-6-2. Selection and subculture
Use 10 mL or the quantity corresponding to 1 g or 1 mL of the LBP to be tested of both portions to inoculate suitable amounts (determined as described under 3-4) of reinforced medium for Clostridia. Incubate under anaerobic conditions at 30-35 °C for 48 h. After incubation, make subcultures from each container on Columbia agar and incubate under anaerobic conditions at 30-35 °C for 48-72 h.

4-6-3. Interpretation
The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction may indicate the presence of Clostridia. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-7. CANDIDA ALBICANS

4-7-1. Sample preparation and pre-enrichment
Prepare the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to not less than 1 g or 1 mL to inoculate 100 mL of Sabouraud-dextrose broth and mix. Incubate at 30-35 °C for 3-5 days.

4-7-2. Selection and subculture
Subculture on Sabouraud-dextrose agar and incubate at 30-35 °C for 24-48 h.

4-7-3. Interpretation
Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

5. APPROACHES FOR TESTING SPECIFIED MICRO-ORGANISMS AND ADDITIONAL TESTING

This section should be understood as informative suggestion. Other procedures are possible as far as they are justified.

If the detection of the specified micro-organism is inhibited by the LBP, its detection is carried out under conditions that neutralise the inhibition or limit the growth of the LBP micro-organisms. The modified test for specified micro-organisms is validated using the appropriate validation parameters depending on the extent of the modifications while ensuring that the same result (presence/absence) is achieved for the specified micro-organism.

A suitable combination of antibiotics may be used to inhibit the LBP and detect the specified micro-organism.
For example, for LBP samples containing *S. cerevisiae*, var. *boulardii*, pre-enrichment and selective media (Sabouraud-dextrose broth and agar) can be supplemented with chloramphenicol and cycloheximide to detect contaminant *C. albicans*.

Alternative pre-enrichment media (e.g. buffered peptone medium for *Salmonella* — see general chapter *2.6.31*), media and test/growth conditions may be used to support growth of the target micro-organisms while limiting growth of the micro-organisms of the LBP.

LBP containing *Bacillus clausii* spores are tested for contaminating *Bacillus cereus* on chromogenic selective agar media plates. Incubation time and temperature depends on the specific medium.

A proposed approach to detect *Bacillus cereus* is described below.

Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount of casein soya bean digest broth, mix and incubate at 35-37 °C for 18-24 h. Subculture on selective media (e.g. *B. cereus* Mossel agar). For each LBP to be tested, validate incubation time and temperature. The appearance of *B. cereus* colonies depends on the medium used. The LBP complies with the test if no *B. cereus* colonies are present.

For LBP containing *E. coli*, use *Enterococcus faecalis* and *Enterococcus faecium* as microbial indicators of faecal contamination to replace the test for absence of *E. coli*. Use selective or differential chromogenic media and, for each LBP to be tested, validate incubation time and temperature. The LBP complies with the test when there is no growth of *Enterococcus* spp.

A search for pathogenic *E. coli* strains may be carried out by suitable methods (e.g. molecular methods for the detection of gene *stx* or *eae*) based on risk-assessment.

6. RECOMMENDED SOLUTIONS AND CULTURE MEDIA

The solutions and culture media mentioned in this chapter and described in chapter *2.6.13* have been found satisfactory for bile-tolerant Gram-negative bacteria, *E. coli*, *P. aeruginosa*, *S. aureus*, Clostridia, *Salmonella* and *C. albicans*. Other media may be used provided that their suitability can be demonstrated and the analytical method where they are used is validated with the appropriate validation parameters.

Appendix XVII

A. Particle Size of Powders

1. Particle Size Classification of Powders (Sieve Test)

(Ph. Eur. method 2.9.12)

The degree of fineness of a powder may be expressed by reference to sieves that comply with the specifications for non-analytical sieves (*2.1.4*).

Where the degree of fineness of powders is determined by sieving, it is defined in relation to the sieve number(s) used either by means of the following terms or, where such terms cannot be used, by expressing the fineness of the powder as a percentage *m/m* passing the sieve(s) used.

The following terms are used in the description of powders:

Coarse powder
Not less than 95 per cent by mass passes through a number 1400 sieve and not more than 40 per cent by mass passes through a number 355 sieve.

Moderately fine powder
Not less than 95 per cent by mass passes through a number 355 sieve and not more than 40 per cent by mass passes through a number 180 sieve.

Fine powder
Not less than 95 per cent by mass passes through a number 180 sieve and not more than 40 per cent by mass passes through a number 125 sieve.

Very fine powder
Not less than 95 per cent by mass passes through a number 125 sieve and not more than 40 per cent by mass passes through a number 90 sieve.

If a single sieve number is given, not less than 97 per cent of the powder passes through the sieve of that number, unless otherwise prescribed.

Assemble the sieves and operate in a suitable manner until sifting is practically complete. Weigh the separated fractions of the powder.

Additional points for monographs other than those of the European Pharmacopoeia

Within the monographs of the British Pharmacopoeia, the above terms may be used to specify the degree of coarseness or fineness of a medicinal or pharmaceutical substance in powder form that is to be incorporated into a formulated preparation. The following terms may also be used for such purposes.

When the use of sieves is inappropriate, the definition is expressed in terms of the particle size as determined by suitable microscopical examination.

Moderately coarse powder Not less than 95% by weight passes through a number 710 sieve and not more than 40% by weight passes through a number 250 sieve.

Microfine powder Not less than 90% by weight passes through a number 45 sieve.

Superfine powder Not less than 90% by number of the particles are less than 10 µm in size.

2. Powder Fineness[1]

(Ph. Eur. method 2.9.35)

Particle-size distribution is estimated by analytical sieving (*2.9.38*) or by application of other suitable methods where appropriate. A simple descriptive classification of powder fineness is provided in this chapter. For practical reasons, sieves are commonly used to measure powder fineness. Sieving is most suitable where a majority of the particles are larger than about 75 µm, although it can be used for some powders having smaller particle sizes where the method can be validated. Light diffraction is also a widely used technique for measuring the size of a wide range of particles.

Where the cumulative distribution has been determined by analytical sieving or by application of other methods, particle size may be characterised in the following manner:

x_{90} = particle size corresponding to 90 per cent of the cumulative undersize distribution;

x_{50} = median particle size (i.e. 50 per cent of the particles are smaller and 50 per cent of the particles are larger);

x_{10} = particle size corresponding to 10 per cent of the cumulative undersize distribution.

It is recognised that the symbol d is also widely used to designate these values. Therefore, the symbols d_{90}, d_{50}, d_{10} may be used.

The following parameters may be defined based on the cumulative distribution.

$Q_r(x)$ = cumulative distribution of particles with a dimension less than or equal to x where the subscript r reflects the distribution type.

r	Distribution type
0	Number
1	Length
2	Area
3	Volume

Therefore, by definition:

$Q_r(x) = 0.90$ when $x = x_{90}$

$Q_r(x) = 0.50$ when $x = x_{50}$

$Q_r(x) = 0.10$ when $x = x_{10}$

An alternative but less informative method of classifying powder fineness is by use of the descriptive terms in Table 2.9.35.-1.

Table 2.9.35.-1.

Classification of powders by fineness		
Descriptive term	x_{50} (µm)	Cumulative distribution by volume basis, $Q_3(x)$
Coarse	> 355	$Q_3(355) < 0.50$
Moderately fine	180 - 355	$Q_3(180) < 0.50$ and $Q_3(355) \geq 0.50$
Fine	125 - 180	$Q_3(125) < 0.50$ and $Q_3(180) \geq 0.50$
Very fine	≤ 125	$Q_3(125) \geq 0.50$

[1] *See the International Standard ISO 3310/1 (1975).*

B. Sieves and Filters

1. Sieves

(Ph. Eur. method 2.1.4)

Sieves are constructed of suitable materials with square meshes. For purposes other than analytical procedures, sieves with circular meshes may be used, the internal diameters of which are 1.25 times the aperture of the square mesh of the corresponding sieve size. There must be no reaction between the material of the sieve and the substance being sifted. Degree of comminution is prescribed in the monograph using the sieve number, which is the size of the mesh in micrometres, given in parenthesis after the name of the substance (Table 2.1.4.-1).

Maximum tolerance[1] for an aperture (+ X): no aperture size shall exceed the nominal size by more than X, where:

$$X = \frac{2(w^{0.75})}{3} + 4(w^{0.25})$$

w = width of aperture.

Tolerance for mean aperture (± Y): the average aperture size shall not depart from the nominal size by more than ± Y, where:

$$Y = \frac{w^{0.98}}{27} + 1.6$$

Intermediary tolerance (+ Z): not more than 6 per cent of the total number of apertures shall have sizes between "nominal + X" and "nominal + Z", where:

$$Z = \frac{X + Y}{2}$$

Wire diameter d: the wire diameters given in Table 2.1.4.-1 apply to woven metal wire cloth mounted in a frame. The nominal sizes of the wire diameters may depart from these values within the limits d_{max} and d_{min}. The limits define a permissible range of choice ± 15 per cent of the recommended nominal dimensions. The wires in a test sieve shall be of a similar diameter in warp and weft directions.

[1] *See the International Standard ISO 3310/1 (1975).*

40 - 100	Fine filtration, filtration of mercury, fine dispersion of gases
100 - 160	Filtration of coarse materials, dispersion and washing of gases, support for other filter materials
160 - 500	Filtration of very coarse materials, dispersion and washing of gases.

3. Particle-size Distribution Estimation by Analytical Sieving[4]

(Ph. Eur. method 2.9.38)

Sieving is one of the oldest methods of classifying powders and granules by particle-size distribution. When using a woven sieve cloth, the sieving will essentially sort the particles by their intermediate size dimension (i.e. breadth or width). Mechanical sieving is most suitable where the majority of the particles are larger than about 75 µm. For smaller particles, their light weight provides insufficient force during sieving to overcome the surface forces of cohesion and adhesion that cause the particles to stick to each other and to the sieve, and thus cause particles that would be expected to pass through the sieve to be retained. For such materials other means of agitation such as air-jet sieving or sonic-sifter sieving may be more appropriate. Nevertheless, sieving can sometimes be

[2] *The given limits are only approximate.*

[3] *The European Pharmacopoeia has adopted the system proposed by the International Organization for Standardization (ISO).*

[4] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

used for some powders or granules having median particle sizes smaller than 75 µm where the method can be validated. In pharmaceutical terms, sieving is usually the method of choice for classification of the coarser grades of single powders or granules. It is a particularly attractive method in that powders and granules are classified only on the basis of particle size, and in most cases the analysis can be carried out in the dry state.

Among the limitations of the sieving method are the need for an appreciable amount of sample (normally at least 25 g, depending on the density of the powder or granule, and the diameter of the test sieves) and the difficulty in sieving oily or other cohesive powders or granules that tend to clog the sieve openings. The method is essentially a two-dimensional estimate of size because passage through the sieve aperture is frequently more dependent on maximum width and thickness than on length.

This method is intended for estimation of the total particle-size distribution of a single material. It is not intended for determination of the proportion of particles passing or retained on 1 or 2 sieves.

Estimate the particle-size distribution as described under Dry sieving method, unless otherwise specified in the individual monograph. Where difficulty is experienced in reaching the endpoint (i.e. material does not readily pass through the sieves) or when it is necessary to use the finer end of the sieving range (below 75 µm), serious consideration must be given to the use of an alternative particle-sizing method.

Sieving is carried out under conditions that do not cause the test sample to gain or lose moisture. The relative humidity of the environment in which the sieving is carried out must be controlled to prevent moisture uptake or loss by the sample. In the absence of evidence to the contrary, analytical test sieving is normally carried out at ambient humidity. Any special conditions that apply to a particular material must be detailed in the individual monograph.

Principles of analytical sieving

Analytical test sieves are constructed from a woven-wire mesh, which is of simple weave that is assumed to give nearly square apertures and is joined to the base of an open cylindrical container. The basic analytical method involves stacking the sieves on top of one another in ascending degrees of coarseness, and then placing the test powder on the top sieve. The nest of sieves is subjected to a standardised period of agitation, and then the mass of material retained on each sieve is accurately determined. The test gives the mass percentage of powder in each sieve size range.

This sieving process for estimating the particle-size distribution of a single pharmaceutical powder is generally intended for use where at least 80 per cent of the particles are larger than 75 µm. The size parameter involved in determining particle-size distribution by analytical sieving is the length of the side of the minimum square aperture through which the particle will pass.

TEST SIEVES

Test sieves suitable for pharmacopoeial tests conform to the current edition of *ISO 3310-1: Test sieves – Technical requirements and testing - Part 1: Test sieves of metal wire cloth* (see Table 2.9.38.-1). Unless otherwise specified in the monograph, use those ISO sieves listed as principal sizes in Table 2.9.38.-1 that are recommended in the particular region.

Sieves are selected to cover the entire range of particle sizes present in the test sample. A nest of sieves having a $\sqrt{2}$ progression of the area of the sieve openings is recommended. The nest of sieves is assembled with the coarsest screen at the top and the finest at the bottom. Use micrometres or millimetres in denoting test sieve openings.

Test sieves are made from stainless steel or, less preferably, from brass or another suitable non-reactive wire.

Calibration and recalibration of test sieves is in accordance with the current edition of ISO 3310-1. Sieves are carefully examined for gross distortions and fractures, especially at their screen frame joints, before use. Sieves may be calibrated optically to estimate the average opening size, and opening variability, of the sieve mesh. Alternatively, for the evaluation of the effective opening of test sieves in the size range of 212-850 µm, standard glass spheres are available. Unless otherwise specified in the individual monograph, perform the sieve analysis at controlled room temperature and at ambient relative humidity.

Cleaning test sieves Ideally, test sieves are cleaned using only a low-pressure air jet or a liquid stream. If some apertures remain blocked by test particles, careful gentle brushing may be used as a last resort.

Test sample

If the test sample mass is not given in the monograph for a particular material, use a test sample having a mass of 25-100 g, depending on the bulk density of the material, for test sieves having a 200 mm diameter. For 76 mm sieves, the amount of material that can be accommodated is approximately 1/7 that which can be accommodated by a 200 mm sieve. Determine the most appropriate mass for a given material by test sieving accurately weighed samples of different masses, such as 25 g, 50 g and 100 g, for the same time period on a mechanical shaker (note: if the test results are similar for the 25 g and 50 g samples, but the 100 g sample shows a lower percentage through the finest sieve, the 100 g sample size is too large). Where only a sample of 10-25 g is available, smaller diameter test sieves conforming to the same mesh specifications may be substituted, but the endpoint must be redetermined. The use of test samples having a smaller mass (e.g. down to 5 g) may be needed. For materials with low apparent particle density, or for materials mainly comprising particles with a highly iso-diametrical shape, sample masses below 5 g for a 200 mm screen may be necessary to avoid excessive blocking of the sieve. During validation of a particular sieve-analysis method, it is expected that the problem of sieve blocking will have been addressed.

If the test material is prone to absorbing or losing significant amounts of water with varying humidity, the test must be carried out in an appropriately controlled environment. Similarly, if the test material is known to develop an electrostatic charge, careful observation must be made to ensure that such charging does not influence the analysis. An antistatic agent, such as colloidal silicon dioxide and/or aluminum oxide, may be added at a 0.5 per cent (*m/m*) level to minimise this effect. If both of the above effects cannot be eliminated, an alternative particle-sizing technique must be selected.

Agitation methods

Several different sieve and powder-agitation devices are commercially available, all of which may be used to perform sieve analyses. However, the different methods of agitation may give different results for sieve analyses and endpoint determinations because of the different types and magnitudes of the forces acting on the individual particles under test.

	40 µm					
		38 µm			38	391

Methods using mechanical agitation or electromagnetic agitation, and that can induce either a vertical oscillation or a horizontal circular motion, or tapping or a combination of both tapping and horizontal circular motion are available. Entrainment of the particles in an air stream may also be used. The results must indicate which agitation method was used and the agitation parameters used (if they can be varied), since changes in the agitation conditions will give different results for the sieve analysis and endpoint determination, and may be sufficiently different to give a failing result under some circumstances.

Endpoint determination

The test sieving analysis is complete when the mass on any of the test sieves does not change by more than 5 per cent or 0.1 g (10 per cent in the case of 76 mm sieves) of the previous mass on that sieve. If less than 5 per cent of the total sample mass is present on a given sieve, the endpoint for that sieve is increased to a mass change of not more than 20 per cent of the previous mass on that sieve.

If more than 50 per cent of the total sample mass is found on any one sieve, unless this is indicated in the monograph, the test is repeated, but with the addition to the sieve nest of a more coarse sieve intermediate between that carrying the excessive mass and the next coarsest sieve in the original nest, i.e. addition of the ISO series sieve omitted from the nest of sieves.

SIEVING METHODS

Mechanical agitation (Dry sieving method)

Tare each test sieve to the nearest 0.1 g. Place an accurately weighed quantity of test sample on the top (coarsest) sieve, and replace the lid. Agitate the nest of sieves for 5 min, then carefully remove each sieve from the nest without loss of material. Reweigh each sieve, and determine the mass of material on each one. Determine the mass of material in the collecting pan in a similar manner. Re-assemble the nest of sieves, and agitate for 5 min. Remove and weigh each sieve as previously described. Repeat these steps until the endpoint criteria are met (see Endpoint determination under Test sieves). Upon completion of the analysis, reconcile the masses of material. Total loss must not exceed 5 per cent of the mass of the original test sample.

Repeat the analysis with a fresh sample, but using a single sieving time equal to that of the combined times used above. Confirm that this sieving time conforms to the requirements for endpoint determination. When this endpoint has been validated for a specific material, then a single fixed time of sieving may be used for future analyses, providing the particle-size distribution falls within normal variation.

If there is evidence that the particles retained on any sieve are aggregates rather than single particles, the use of mechanical dry sieving is unlikely to give good reproducibility, and a different particle-size analysis method must be used.

Air-entrainment methods (Air-jet and sonic-sifter sieving)

Different types of commercial equipment that use a moving air current are available for sieving. A system that uses a single sieve at a time is referred to as air-jet sieving. It uses the same general sieving methodology as that described under Dry sieving method, but with a standardised air jet replacing the normal agitation mechanism. It requires sequential analyses on individual sieves starting with the finest sieve to obtain a particle-size distribution. Air-jet sieving often includes the use of finer test sieves than used in ordinary dry sieving. This technique is more suitable where only oversize or undersize fractions are needed.

In the sonic-sifter method, a nest of sieves is used, and the test sample is carried in a vertically oscillating column of air that lifts the sample and then carries it back against the mesh openings at a given number of pulses per minute. It may be necessary to lower the sample amount to 5 g when sonic sifting is employed.

The air-jet sieving and sonic-sifter sieving methods may be useful for powders or granules when the mechanical sieving techniques are incapable of giving a meaningful analysis.

These methods are highly dependent upon proper dispersion of the powder in the air current. This requirement may be hard to achieve if the method is used at the lower end of the sieving range (i.e. below 75 µm), when the particles tend to be more cohesive, and especially if there is any tendency for the material to develop an electrostatic charge. For the above reasons endpoint determination is particularly critical, and it is very important to confirm that the oversize material comprises single particles and is not composed of aggregates.

INTERPRETATION

The raw data must include the mass of the test sample, the total sieving time, the precise sieving methodology, and the set values for any variable parameters, in addition to the masses retained on the individual sieves and in the pan.

It may be convenient to convert the raw data into a cumulative mass distribution, and if it is desired to express the distribution in terms of a cumulative mass undersize, the range of sieves used must include a sieve through which all the material passes. If there is evidence on any of the test sieves that the material remaining on it is composed of aggregates formed during the sieving process, the analysis is invalid.

C. Specific Surface Area by Air Permeability

(Ph. Eur. method 2.9.14)

The test is intended for the determination of the specific surface area of dry powders expressed in square metres per gram in the sub-sieve region. The effect of molecular flow ("slip flow") which may be important when testing powders consisting of particles less than a few micrometres is not taken into account in the equation used to calculate the specific surface area.

APPARATUS

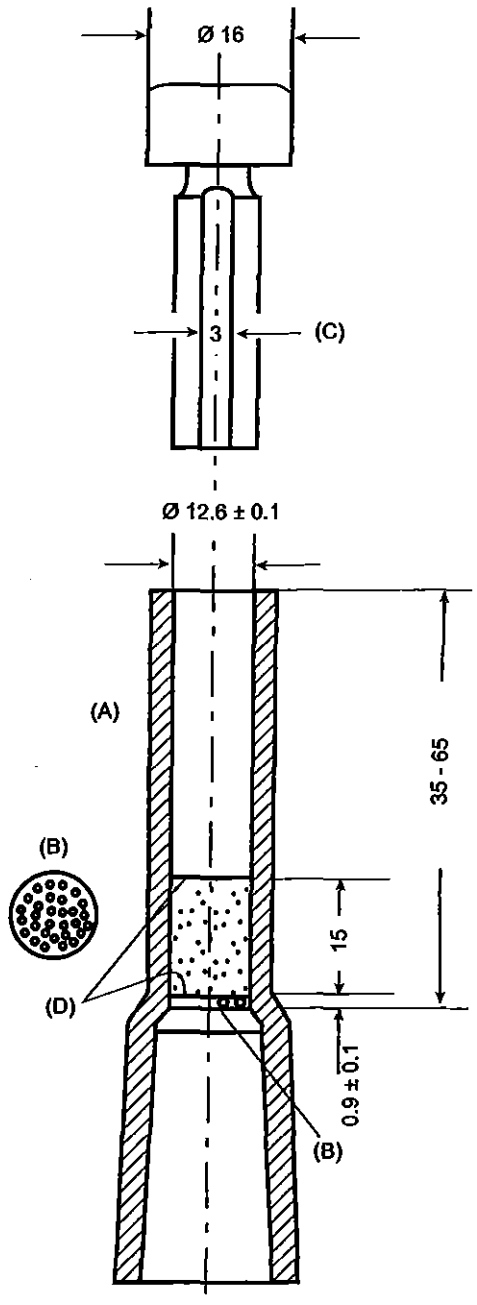

Figure 2.9.14.-1. – *Permeability cell*
Dimensions in millimetres

The apparatus consists of the following parts:

(a) a *permeability cell* (see Figure 2.9.14.-1), which consists of a cylinder with an inner diameter of 12.6 ± 0.1 mm (*A*), constructed of glass or non-corroding metal. The bottom of the cell forms an airtight connection (for example, via an adapter) with the manometer (Figure 2.9.14.-2). A ledge 0.5-1 mm in width is located 50 ± 15 mm from the top of the cell. It is an integral part of the cell or firmly fixed so as to be airtight. It supports a perforated metal disk (*B*), constructed of non-corroding metal. The disk has a thickness

of 0.9 ± 0.1 mm and is perforated with 30 to 40 holes 1 mm in diameter evenly distributed over this area.

The plunger (*C*) is made of non-corroding metal and fits into the cell with a clearance of not more than 0.1 mm.

The bottom of the plunger has sharp square edges at right angles to the principal axis. There is an air vent 3 mm long and 0.3 mm deep on one side of the plunger. The top of the plunger has a collar such that when the plunger is placed in the cell and the collar is brought into contact with the top of the cell, the distance between the bottom of the plunger and the top of the perforated disk (*B*) is 15 ± 1 mm.

The filter paper disks (*D*) have smooth edges and the same diameter as the inside of the cell.

(b) a *U-tube manometer* (*E*) (Figure 2.9.14.-2) is made of nominal 9 mm outer diameter and 7 mm inner diameter glass tubing with standard walls. The top of one arm of the manometer forms an airtight connection with the permeability cell (*F*). The manometer arm connected to the permeability cell has a line etched around the tube at 125-145 mm below the top of the side outlet and three other lines at distances of 15 mm, 70 mm and 110 mm above that line (*G*). The side outlet, 250-305 mm above the bottom of the manometer, is used to evacuate the manometer arm connected to the permeability cell. A tap is provided on the side outlet not more than 50 mm from the manometer arm.

The manometer is mounted firmly in such a manner that the arms are vertical. It is filled to the lowest mark with the liquid recommended by the manufacturer of the equipment or water.

METHOD

If prescribed, dry the powder to be examined and sift through a suitable sieve (for example no. 125) to disperse agglomerates. Calculate the mass (*M*) of the powder to be used from the following expression:

$$V \times \rho \times (1 - \varepsilon) \qquad (1)$$

V = bulk volume of the compacted bed of powder,
ρ = density of the substance to be examined in grams per millilitre,
ε = porosity of the compacted bed of powder.

Assume first a porosity of 0.5 and introduce this value in expression (1) to calculate the mass (*M*) of the powder to be examined.

Place a filter paper disk on top of the perforated metal disk (*B*). Weigh the calculated mass (*M*) of the powder to be examined to the nearest 1 mg. Carefully transfer the powder into the cleaned, tared permeability cell and carefully tap the cell so that the surface of the powder bed is level and cover it with a second filter paper disk. Slowly compact the powder by means of the plunger, avoiding rotary movement. Maintain the pressure until the plunger is completely inserted into the permeability cell. If this is not possible, decrease the quantity of the powder used. If, on the contrary, there is not enough resistance, increase the quantity of the powder. In this case calculate the porosity again. After at least 10 s, remove the plunger.

Attach the permeability cell to the tube of the manometer by means of an airtight connection. Evacuate the air from the manometer by means of a rubber bulb until the level of the coloured liquid is at the highest mark. Close the tap and check that the apparatus is airtight by closing the upper end of the cell, for example with a rubber stopper. Remove the stopper and, using a timer, measure the time taken for the liquid to fall from the second to the third mark.

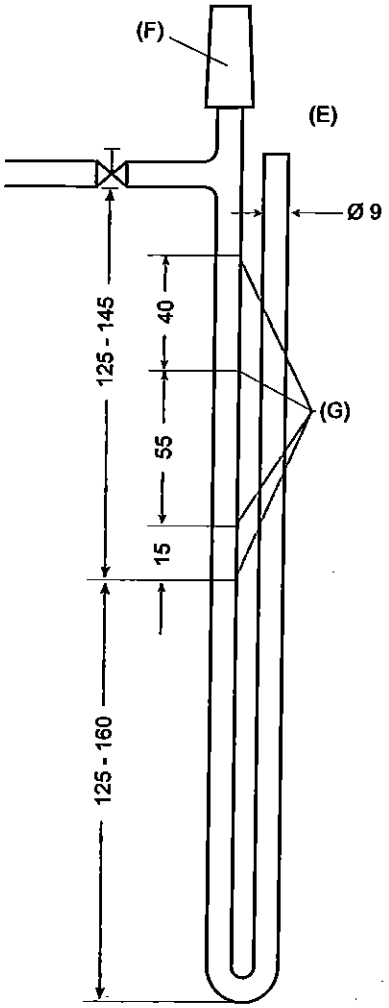

Figure 2.9.14.-2. – *Manometer*
Dimensions in millimetres

Using the measured flow time, calculate the specific surface area (*S*), expressed in square metres per gram, from the following expression:

$$\frac{K \times \sqrt{\varepsilon^3} \times \sqrt{t}}{\rho \times (1 - \varepsilon) \times \sqrt{\eta}} \qquad (2)$$

t = flow time in seconds,
η = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1),
K = apparatus constant determined according to expression (4),
ρ = density of the substance to be examined in grams per millilitre,
ε = porosity of the compacted bed of powder.

CALIBRATION OF THE APPARATUS

Bulk volume of the compacted powder bed

It is determined by the mercury displacement method as follows:

Place two filter paper disks in the permeability cell, pressing down the edges with a rod slightly smaller than the cell diameter until the filter disks lie flat on the perforated metal disk; fill the cell with mercury, removing any air bubbles adhering to the wall of the cell and wipe away the excess to create a plane surface of mercury at the top of the cell. If the cell is made of material that will amalgamate, grease the cell and the metal disk first with a thin layer of liquid paraffin. Pour out the mercury into a tared beaker and determine the mass (M_A) and the temperature of the mercury.

Make a compacted bed using the reference powder and again fill the cell with mercury with a planar surface at the top of the cell. Pour out the mercury in a tared beaker and again determine the mass of the mercury (M_B). Calculate the bulk volume (V) of the compacted bed of powder from the following expression:

$$\frac{M_A - M_B}{\rho_{Hg}} \qquad (3)$$

$M_A - M_B$ = difference between the determined masses of mercury in grams,

ρ_{Hg} = density of mercury at the determined temperature in grams per millilitre.

Repeat the procedure twice, changing the powder each time; the range of values for the calculated volume (V) is not greater than 0.01 mL. Use the mean value of the three determined volumes for the calculations.

Apparatus constant (K)

It is determined using a reference powder with known specific surface area and density as follows:

Calculate the required quantity of the reference powder to be used (expression (1)) using the stated density and the determined volume of the compacted powder bed (expression (3)).

Homogenise and loosen up the powder by shaking it for 2 min in a 100 mL bottle. Prepare a compacted powder bed and measure the flow time of air as previously described. Calculate the apparatus constant (K) from the following expression:

$$\frac{S_{sp} \times \rho \times (1 - \epsilon) \times \sqrt{\eta}}{\sqrt{\epsilon^3} \times \sqrt{t}} \qquad (4)$$

S_{sp} = stated specific surface area of the reference powder,
ρ = density of the substance to be examined in grams per millilitre,
ϵ = porosity of the compacted bed of powder,
t = flow time in seconds,
η = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1).

The density of mercury and the viscosity of air over a range of temperatures are shown in Table 2.9.14.-1.

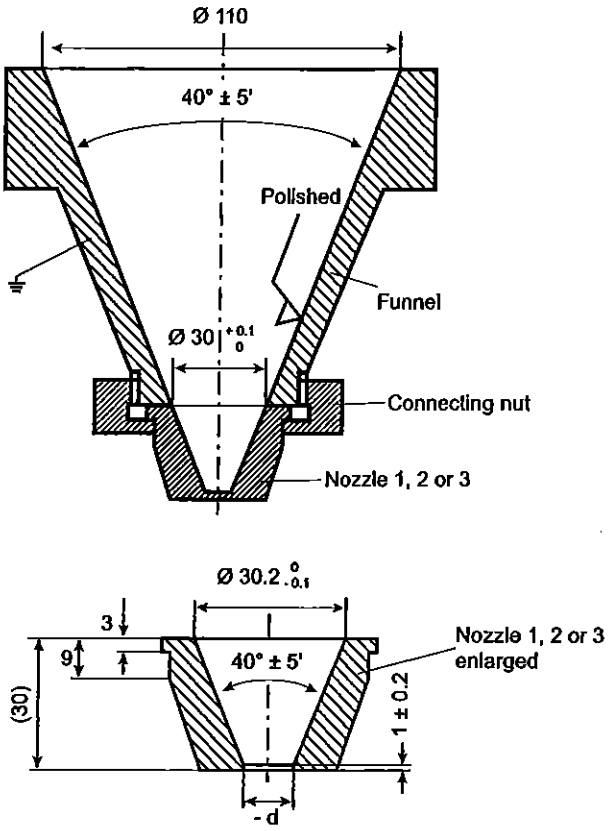
Table 2.9.14.-1.

Temperature (°C)	Density of mercury (g/mL)	Viscosity of air (η) (mPa·s)	$\sqrt{\eta}$
16	13.56	0.01800	0.1342
17	13.56	0.01805	0.1344
18	13.55	0.01810	0.1345
19	13.55	0.01815	0.1347
20	13.55	0.01819	0.1349
21	13.54	0.01824	0.1351
22	13.54	0.01829	0.1353
23	13.54	0.01834	0.1354
24	13.54	0.01839	0.1356

E. Flowability

(Ph. Eur. Method 2.9.16)

The test for flowability is intended to determine the ability of divided solids (for example, powders and granules) to flow vertically under defined conditions.



Nozzle	Diameter (d) of the outflow opening (millimetres)
1	10 ± 0.01
2	15 ± 0.01
3	25 ± 0.01

Figure 2.9.16.-1. – *Flow funnel and nozzle. Nozzle is made of stainless, acid-resistant steel (V4A,CrNi)*

Dimensions in millimetres

APPARATUS

According to the flow properties of the material to be tested, funnels with or without stem, with different angles and orifice diameters are used. Typical apparatuses are shown in Figures 2.9.16.-1 and 2.9.16.-2. The funnel is maintained upright by a suitable device. The assembly must be protected from vibrations.

METHOD

Into a dry funnel, whose bottom opening has been blocked by suitable means, introduce without compacting a test sample weighed with 0.5 per cent accuracy. The amount of the sample depends on the apparent volume and the apparatus used. Unblock the bottom opening of the funnel and measure the time needed for the entire sample to flow out of the funnel. Carry out three determinations.

EXPRESSION OF RESULTS

The flowability is expressed in seconds and tenths of seconds, related to 100 g of sample.

The results depend on the storage conditions of the material to be tested.

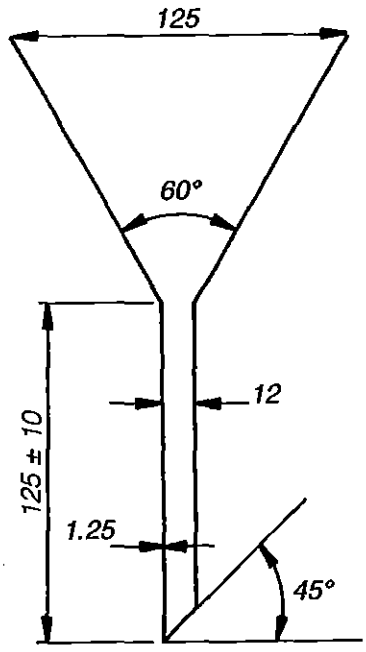


Figure 2.9.16.-2
Dimensions in millimetres

The results can be expressed as the following:

a) the mean of the determinations, if none of the individual values deviates from the mean value by more than 10 per cent;

b) as a range, if the individual values deviate from the mean value by more than 10 per cent;

c) as a plot of the mass against the flow time;

d) as an infinite time, if the entire sample fails to flow through.

F. Measurement of Consistency and Texture Analysis

1. Measurement of Consistency by Penetrometry

(Ph. Eur. method 2.9.9)

This test is intended to measure, under determined and validated conditions, the penetration of an object into the product to be examined in a container with a specified shape and size.

APPARATUS

The apparatus consists of a penetrometer made up of a stand and a penetrating object. A suitable apparatus is shown in Figure 2.9.9.-1.

A. Scale showing the depth of penetration, graduated in tenths of millimetres.

B. Vertical shaft to maintain and guide the penetrating object.

C. Device to retain and to release the penetrating object automatically and for a constant time.

D. Device to ensure that the penetrating object is vertical and that the base is horizontal.

E. Penetrating object (see Figures 2.9.9.-2 and 3).

F. Container.

G. Horizontal base.

H. Control for the horizontal base.

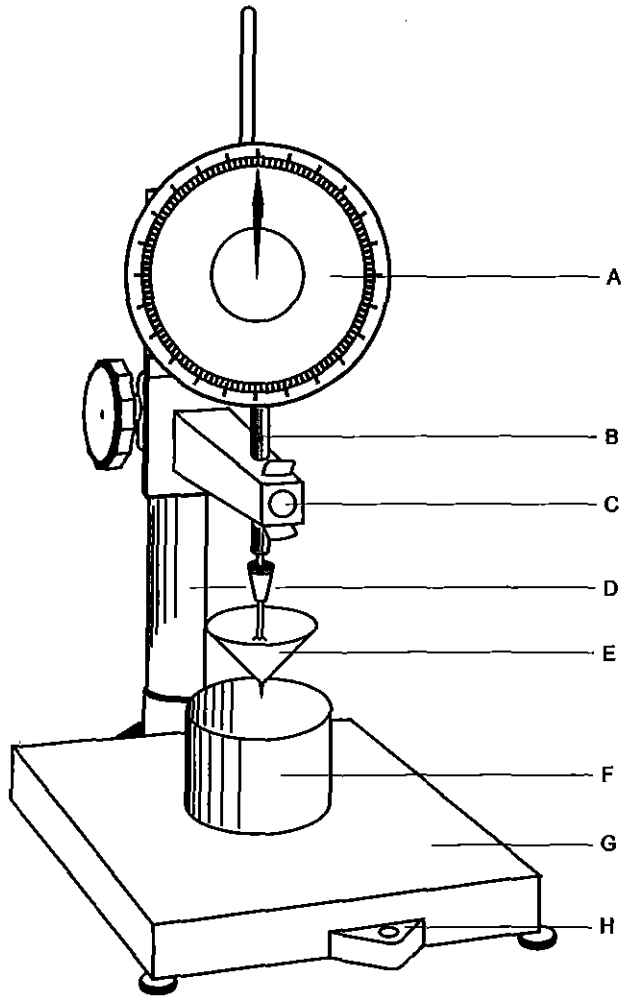

Figure 2.9.9.-1. – *Penetrometer*

The stand is made up of:
- a vertical shaft to maintain and guide the penetrating object;
- a horizontal base;
- a device to ensure that the penetrating object is vertical;
- a device to check that the base is horizontal;
- a device to retain and release the penetrating object;
- a scale showing the depth of penetration, graduated in tenths of a millimetre.

The penetrating object, made of a suitable material, has a smooth surface, and is characterised by its shape, size and mass (*m*).

Suitable penetrating objects are shown in Figures 2.9.9.-2 and 2.9.9.-3.

PROCEDURE

Prepare the test samples according to one of the following procedures.

A. Carefully and completely fill 3 containers, without forming air bubbles. Level if necessary to obtain a flat surface. Store the samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed.

B. Store 3 samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed. Apply a suitable shear to the samples for 5 min. Carefully and completely fill 3 containers, without forming air bubbles, and level if necessary to obtain a flat surface.

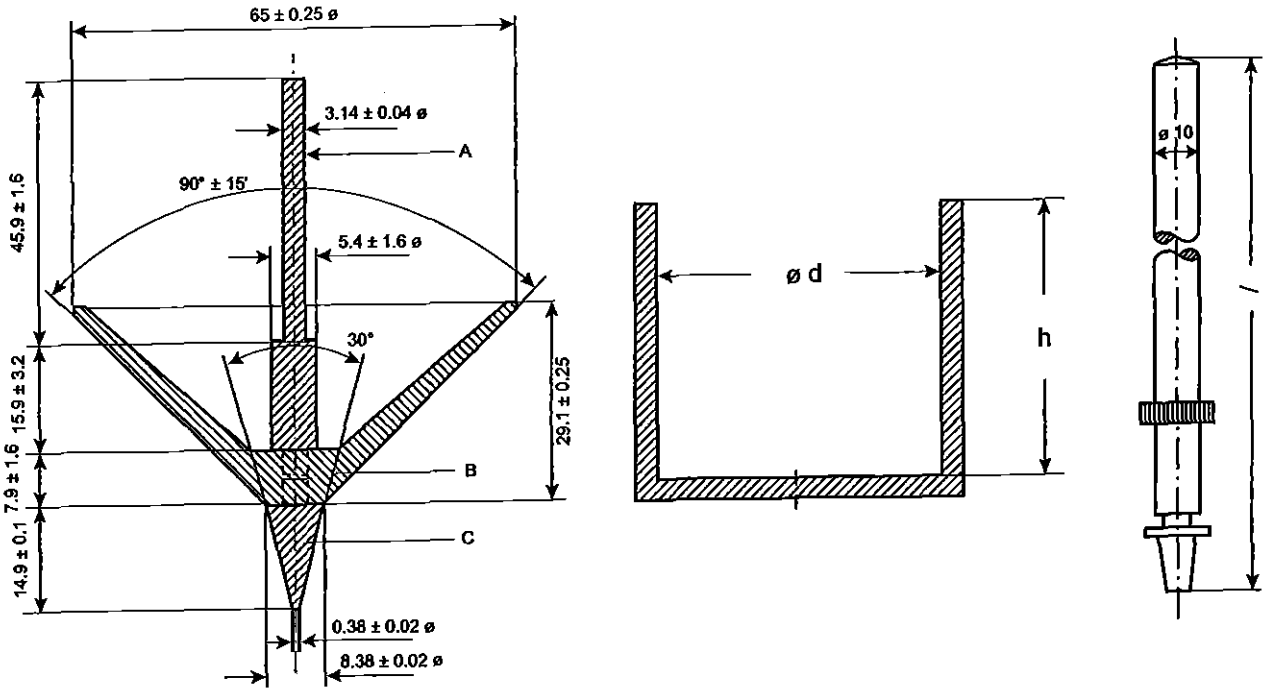

Figure 2.9.9.-2. – *Cone (m = 102.5 ± 0.05 g), suitable container (d = 102 mm or 75 mm; h ≥ 62 mm) and shaft (l = 162 mm; m = 47.5 ± 0.05 g).*
Dimensions in millimetres

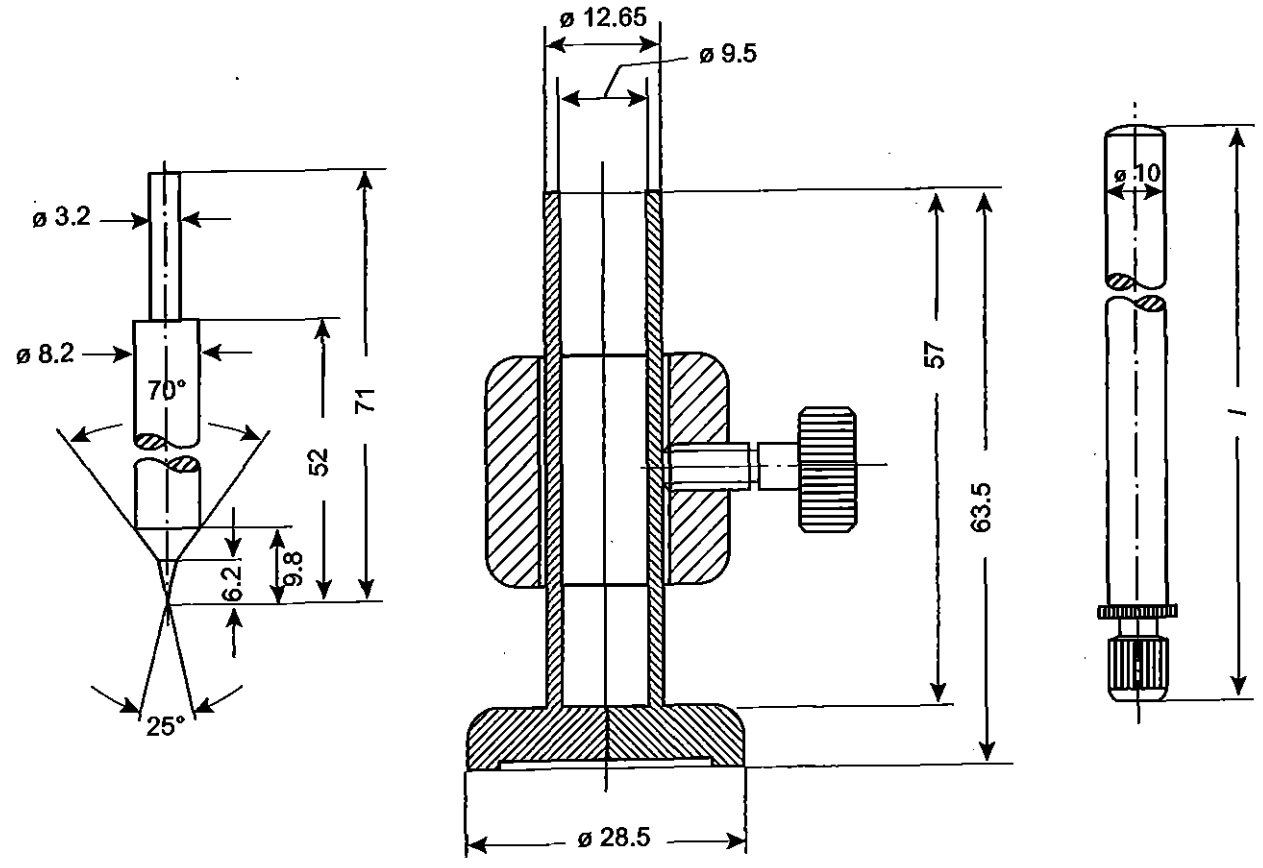

Figure 2.9.9.-3 – *Micro-cone (m = 7.0 g), suitable container and shaft (l = 116 mm; m = 16.8 g)*
Dimensions in millimetres

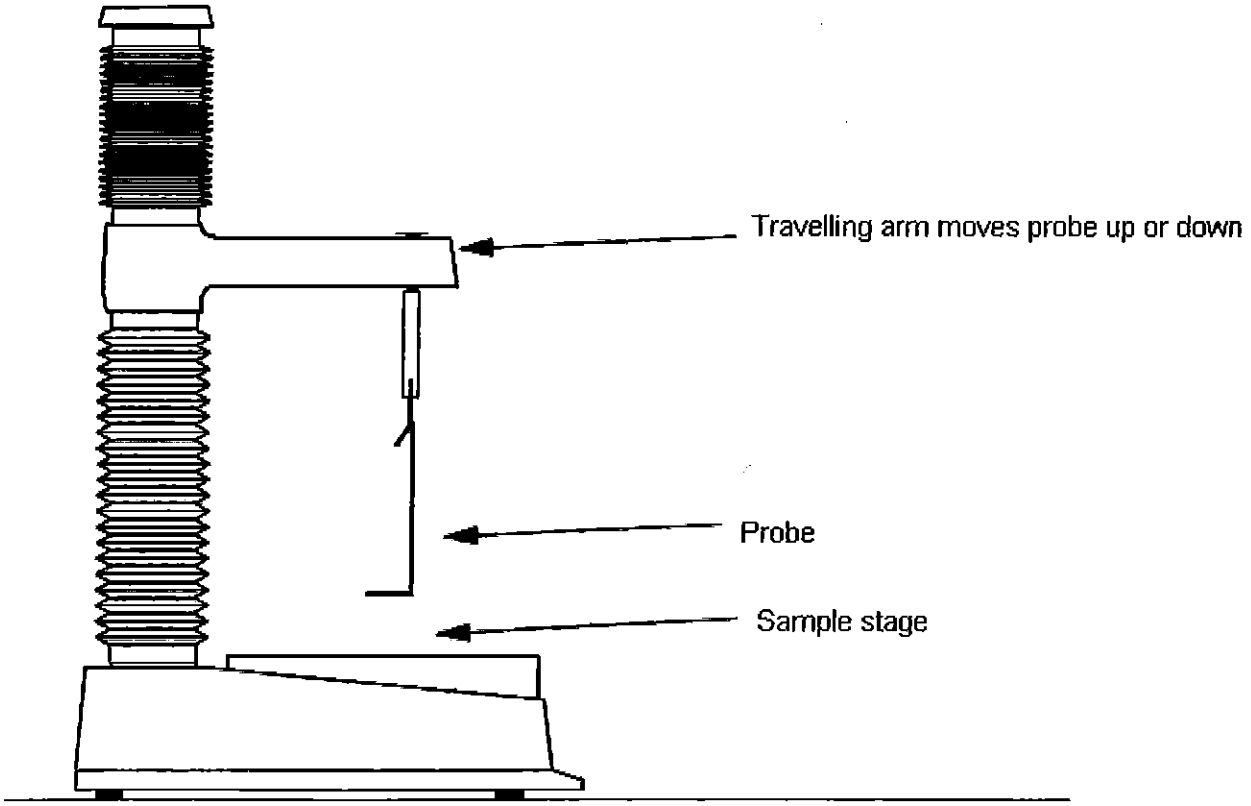

Fig. 17F-1 *Texture Analyser*

C. Melt 3 samples and carefully and completely fill 3 containers, without forming air bubbles. Store the samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed.

Determination of penetration

Place the test sample on the base of the penetrometer. Verify that its surface is perpendicular to the vertical axis of the penetrating object. Bring the temperature of the penetrating object to 25 ± 0.5 °C and then adjust its position such that its tip just touches the surface of the sample. Release the penetrating object and hold it free for 5 s. Clamp the penetrating object and measure the depth of penetration. Repeat the test with the 2 remaining containers.

EXPRESSION OF THE RESULTS

The penetration is expressed in tenths of a millimetre as the arithmetic mean of the 3 measurements. If any of the individual results differ from the mean by more than 3 per cent, repeat the test and express the results of the 6 measurements as the mean and the relative standard deviation.

2. Texture Analysis of Semi-solids or Gels

(No Ph. Eur. method)

This test determines, under defined conditions, the force required to penetrate a semi-solid or gel sample.

This test applies to samples consisting of a semi solid or gel-like mass which retains its form. It is not applicable to suspensions consisting of fine solid particles in a liquid.

Apparatus A suitable texture analyser, (see Fig. 17F-1) consisting of:

- a suitable platform or device to hold the sample being examined,
- a mobile arm that can be moved in a vertical direction towards or away from the sample,
- a probe attachment, which may be of various shapes such as a platen, a cylinder, a cone, a needle, a sphere or a wire,
- a load cell capable of measuring the load or tensile forces experienced by the probe as the mobile arm moves up or down.

Calibration The apparatus is calibrated using a suitable certified weight.

Method Check that the apparatus is vertical.

Place the sample being examined in a suitable holder as specified in the monograph. Programme the apparatus in accordance with the manufacturer's specifications to move the probe up or down at a defined speed or force as specified in the monograph. Measure the forces experienced by the probe through the sample.

The maximum peak force (in g) required to penetrate the sample is measured by the load cell.

Carry out each measurement six times.

G. Friability

1. Uncoated Tablets[1]

(Ph. Eur. method 2.9.7)

This chapter provides guidelines for the friability determination of compressed, uncoated tablets. The test procedure presented in this chapter is generally applicable to most compressed tablets. Measurement of tablet friability

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

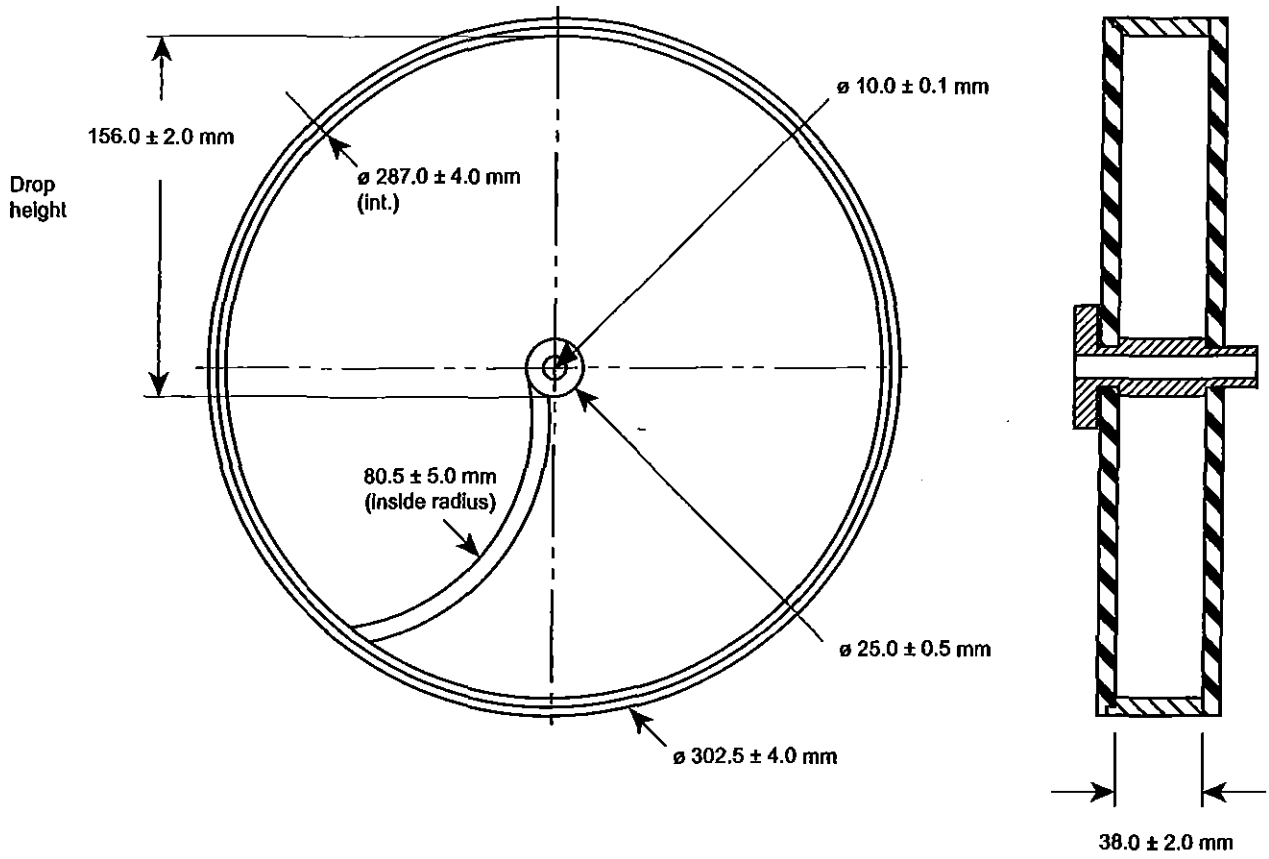

Figure 2.9.7.-1. – *Tablet friability apparatus*

supplements other physical strength measurements, such as tablet breaking force.

Use a drum, with an internal diameter between 283-291 mm and a depth between 36-40 mm, of transparent synthetic polymer with polished internal surfaces, and subject to minimum static build-up (see Figure 2.9.7.-1.). One side of the drum is removable. The tablets are tumbled at each turn of the drum by a curved projection with an inside radius between 75.5-85.5 mm that extends from the middle of the drum to the outer wall. The outer diameter of the central ring is between 24.5-25.5 mm. The drum is attached to the horizontal axis of a device that rotates at 25 ± 1 r/min. Thus, at each turn the tablets roll or slide and fall onto the drum wall or onto each other.

For tablets with a unit mass equal to or less than 650 mg, take a sample of whole tablets corresponding as near as possible to 6.5 g. For tablets with a unit mass of more than 650 mg, take a sample of 10 whole tablets. The tablets are carefully dedusted prior to testing. Accurately weigh the tablet sample, and place the tablets in the drum. Rotate the drum 100 times, and remove the tablets. Remove any loose dust from the tablets as before, and accurately weigh.

Generally, the test is run once. If obviously cracked, cleaved, or broken tablets are present in the tablet sample after tumbling, the sample fails the test. If the results are difficult to interpret or if the weight loss is greater than the targeted value, the test is repeated twice and the mean of the 3 tests determined. A maximum loss of mass (obtained from a single test or from the mean of 3 tests) not greater than 1.0 per cent is considered acceptable for most products.

If tablet size or shape causes irregular tumbling, adjust the drum base so that the base forms an angle of about 10° with the horizontal and the tablets no longer bind together when lying next to each other, which prevents them from falling freely.

Effervescent tablets and chewable tablets may have different specifications as far as friability is concerned. In the case of hygroscopic tablets, a humidity-controlled environment is required for testing.

A drum with dual scooping projections, or apparatus with more than one drum, for the running of multiple samples at one time, are also permitted.

2. Granules and Spheroids

(Ph. Eur. method 2.9.41)

This chapter describes 2 methods for determination of the friability of granules and spheroids, which may be used during development studies. It is recognised, however, that many methods with equal suitability may be used.

This test is intended to determine, under defined conditions, the friability of granules and spheroids. Friability is defined as a reduction in the mass of the granules or spheroids or in the formation of fragments of granules or spheroids, occurring when the granules or spheroids are subjected to mechanical strain during handling (tumbling, vibration, fluidisation, etc.). Examples of changes are abrasion, breakage or deformation of granules or spheroids.

METHOD A

Apparatus (fluidised-bed apparatus)

The apparatus (see Figure 2.9.41.-1) consists of a glass cylinder (A) with a conical lower part. The cylinder is provided with a sieve lid (B) having an aperture size of 500 µm or any other suitable sieve. The conical end is connected to a U-shaped glass tube (C) that can be disconnected from the cylinder for removal of the granules or spheroids. The U-tube is attached to a T-coupling (D).

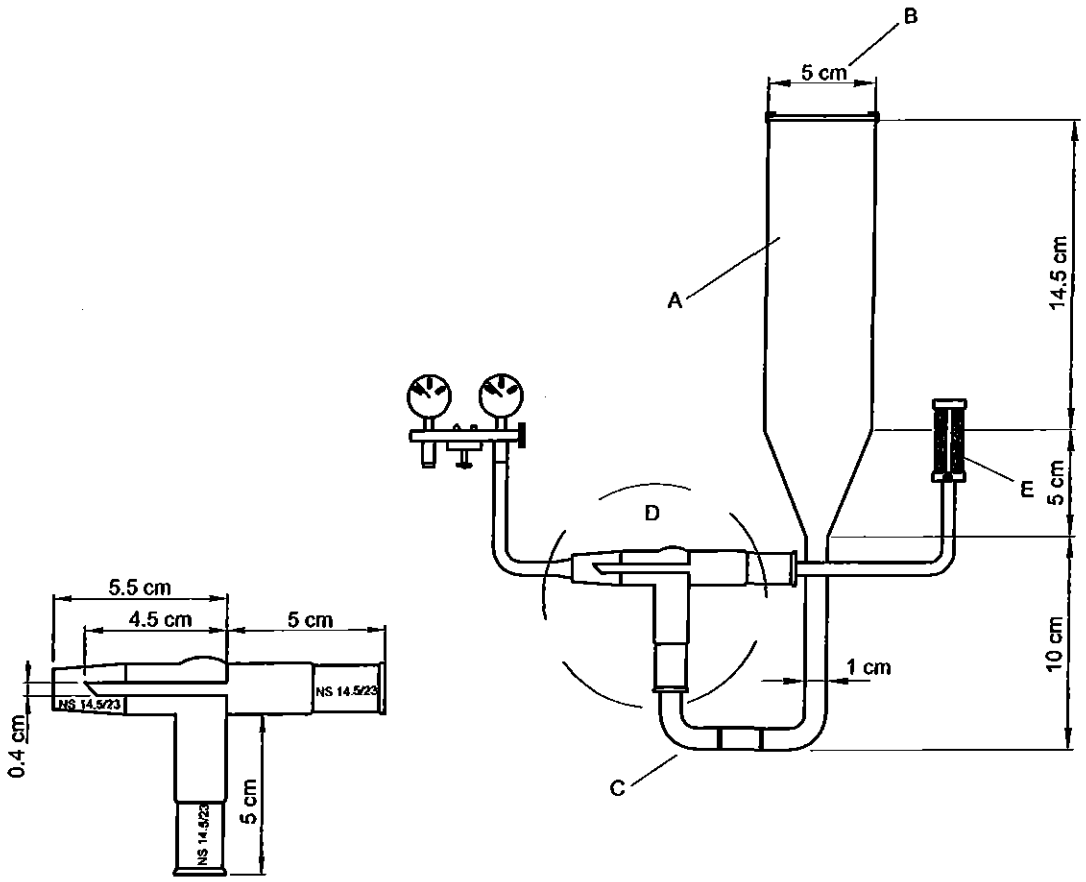

Figure 2.9.41.-1. – *Fluidised-bed apparatus*

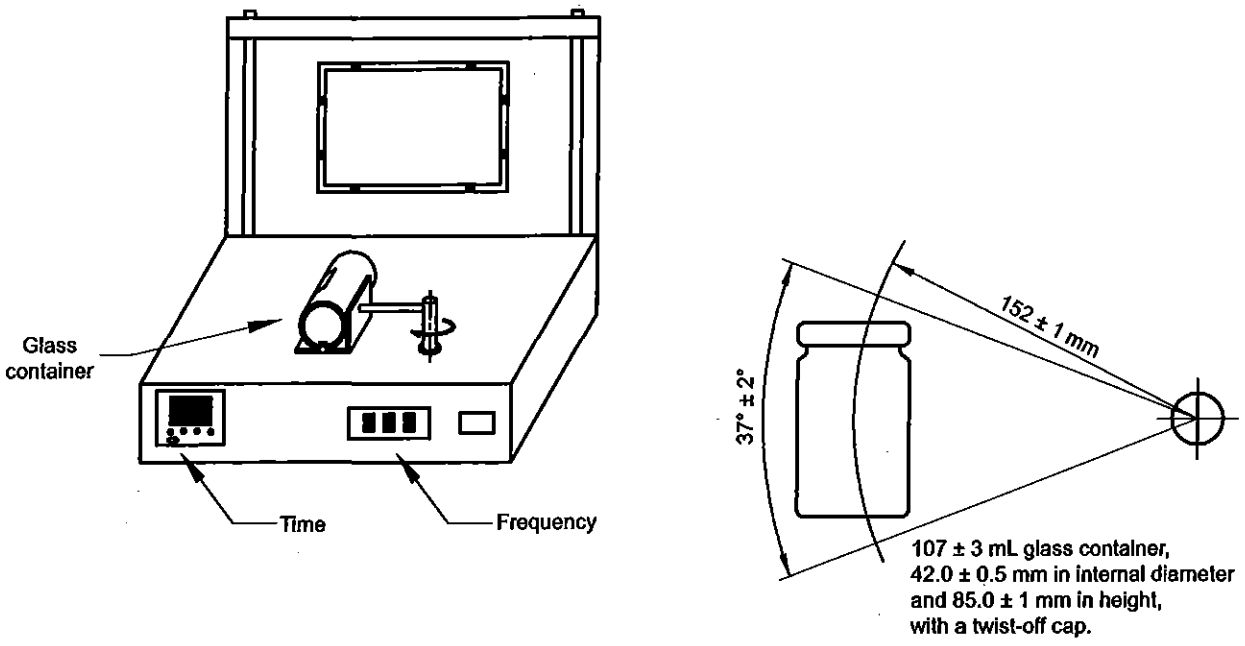

Figure 2.9.41.-2. – *Oscillating apparatus*

One inlet of the T-coupling is joined by a silicone tube to a manometer for regulating the compressed-air flow (use compressed air complying with the test for water in the monograph *Medicinal air (1238)*), the other one is connected via a silicone tube to a by-pass flowmeter (E) (0.10-1.00 $m^3 \cdot h^{-1}$).

Procedure

The following procedure is usually suitable Remove the fine particles by sieving (sieve having an aperture size of 710 µm or any other suitable sieve). Introduce about 8.0 g (m_1) of granules or spheroids into the cylinder (A). Close the apparatus with the sieve lid (B). Adjust the flow rate of the compressed air to 0.45 $m^3 \cdot h^{-1}$. After 15 min, remove the granules or spheroids from the apparatus by

disconnecting the U-tube and weigh again (m_2). Test 3 samples and calculate the mean value. It is recommended to spray the inside of the apparatus with an antistatic agent every 3 determinations in order to prevent electrostatic charging.

Loss on drying Dry in an oven at 105 °C, unless otherwise prescribed. Alternatively, other drying conditions as described in general chapter *2.2.32* may be used.

Calculation

$$F = \frac{m_1(100 - T_1) - m_2(100 - T_2)}{m_1} \times 100$$

F = friability;
T_1 = percentage loss on drying before the test (mean of 2 determinations);
T_2 = percentage loss on drying after the test (mean of 2 determinations);
m_1 = mass of the granules or spheroids before the test, in grams;
m_2 = mass of the granules or spheroids after the test, in grams.

METHOD B

Apparatus (oscillating apparatus)

The apparatus (see Figure 2.9.41.-2) consists of a glass container, containing the granules or spheroids to be examined, which is subjected to horizontal oscillations. The frequency and duration of the oscillations can be varied continuously. The frequency can be adjusted, using a scale, to a value in the range 0-400 oscillations/min. The duration can be set to a value in the range 0-9999 s.

Procedure

The following procedure is usually suitable Remove the fine particles by sieving (sieve having an aperture size of 355 µm or any other suitable sieve). In the glass container, weigh about 10.00 g (m_1) of the granules or spheroids. Install the container in the apparatus. Shake for 240 s at the highest frequency for hard granules or spheroids, or for 120 s at a lower frequency (e.g. 140 oscillations/min) for soft granules or spheroids. Sieve (355 µm, or the same sieve as used previously) and weigh the granules or spheroids again (m_2). Test 3 samples and calculate the mean value.

Loss on drying Dry in an oven at 105 °C, unless otherwise prescribed. Alternatively, other drying conditions as described in general chapter *2.2.32* may be used.

Calculation

$$F = \frac{m_1(100 - T_1) - m_2(100 - T_2)}{m_1} \times 100$$

F = friability;
T_1 = percentage loss on drying before the test (mean of 2 determinations);
T_2 = percentage loss on drying after the test (mean of 2 determinations);
m_1 = mass of the granules or spheroids before the test, in grams;
m_2 = mass of the granules or spheroids after the test, in grams.

H. Resistance to Crushing of Tablets

(Ph. Eur. method 2.9.8)

This test is intended to determine, under defined conditions, the resistance to crushing of tablets, measured by the force needed to disrupt them by crushing.

APPARATUS

The apparatus consists of 2 jaws facing each other, one of which moves towards the other. The flat surfaces of the jaws are perpendicular to the direction of movement. The crushing surfaces of the jaws are flat and larger than the zone of contact with the tablet. The apparatus is calibrated using a system with a precision of 1 newton.

OPERATING PROCEDURE

Place the tablet between the jaws, taking into account, where applicable, the shape, the break-mark and the inscription; for each measurement orient the tablet in the same way with respect to the direction of application of the force. Carry out the measurement on 10 tablets, taking care that all fragments of tablets have been removed before each determination.

This procedure does not apply when fully automated equipment is used.

EXPRESSION OF RESULTS

Express the results as the mean, minimum and maximum values of the forces measured, all expressed in newtons.

Indicate the type of apparatus and, where applicable, the orientation of the tablets.

J. Softening Time Determination of Lipophilic Suppositories

(Ph. Eur. method 2.9.22)

The test is intended to determine, under defined conditions, the time which elapses until a suppository maintained in water softens to the extent that it no longer offers resistance when a defined weight is applied.

APPARATUS A

The apparatus (see Figure 2.9.22.-1) consists of a glass tube 15.5 mm in internal diameter with a flat bottom and a length of about 140 mm. The tube is closed by a removable plastic cover having an opening 5.2 mm in diameter. The apparatus comprises a rod 5.0 mm in diameter which becomes wider towards the lower end, reaching a diameter of 12 mm. A metal needle 2 mm in length and 1 mm in diameter is fixed on the flat underside.

The rod consists of 2 parts, a lower part made of plastic material and an upper part made of plastic material or metal with a weight disk. The upper and lower parts are either fitted together (manual version) or separate (automated version). The weight of the entire rod is 30 ± 0.4 g. The upper part of the rod carries a sliding mark ring. When the rod is introduced into the glass tube so that it touches the bottom, the mark ring is adjusted to coincide with the upper level of the plastic cover.

Method

Place the glass tube containing 10 mL of water in a water-bath and equilibrate at 36.5 ± 0.5 °C. Fix the glass tube vertically and immerse to a depth of at least 7 cm below the surface but without touching the bottom of the water-bath. Introduce a suppository, tip first, into the tube followed by the rod with the free gliding plastic cover into the glass tube until the metal needle touches the flat end of the suppository. Put the cover on the tube (beginning of time measurement). Note the time which elapses until the rod sinks down to the bottom of the glass tube and the mark ring reaches the upper level of the plastic cover.

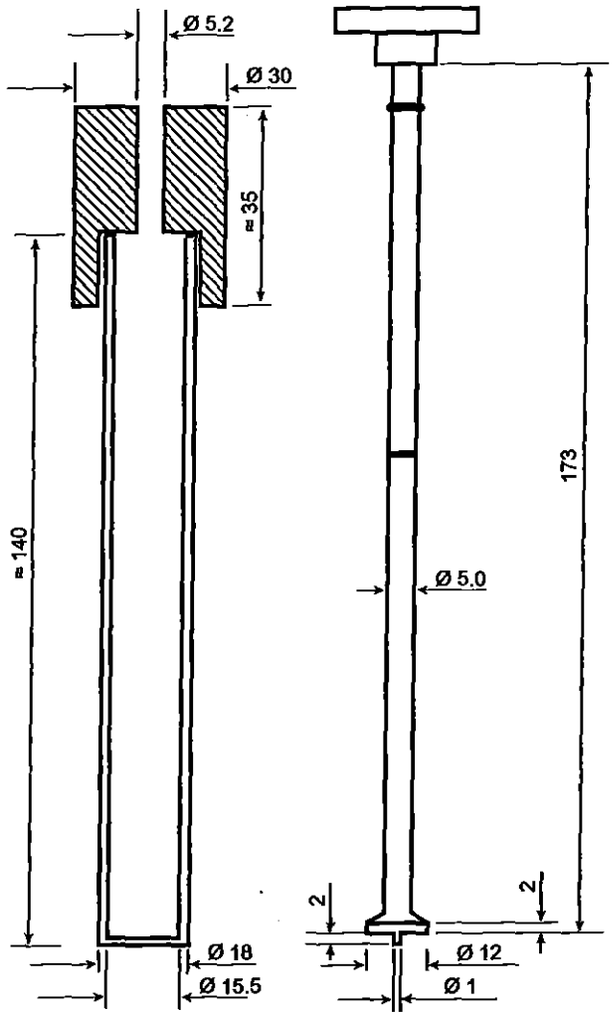

Figure 2.9.22.-1. – *Apparatus A for measuring the softening time of lipophilic suppositories*

Dimensions in millimetres

APPARATUS B

The apparatus (see Figure 2.9.22.-2) consists of a water-bath (B) into which an inner tube (A) is inserted and fixed with a stopper. The inner tube is closed by a stopper at the bottom. The apparatus is fitted with a thermometer. 2 insets are available:

— a glass rod (C1) in the form of a tube sealed at both ends, carrying a rim at its lower end weighed with lead shot, which has a weight of 30 ± 0.4 g,

— a penetration inset (C2) consisting of a rod (7.5 ± 0.1 g) in a tube which has an enlargement for the suppository, both made of stainless steel.

Method

Pour 5 mL of water at 36.5 ± 0.5 °C into the inner tube (A), introduce a suppository with the tip downwards and onto that, place the inset (C1 or C2). Note the time which elapses between this moment and the moment when the lower, rimmed end of the glass rod (C1) or the steel rod (C2) reaches the narrowed part of the inner glass tube. Melting or dissolution is then considered as complete.

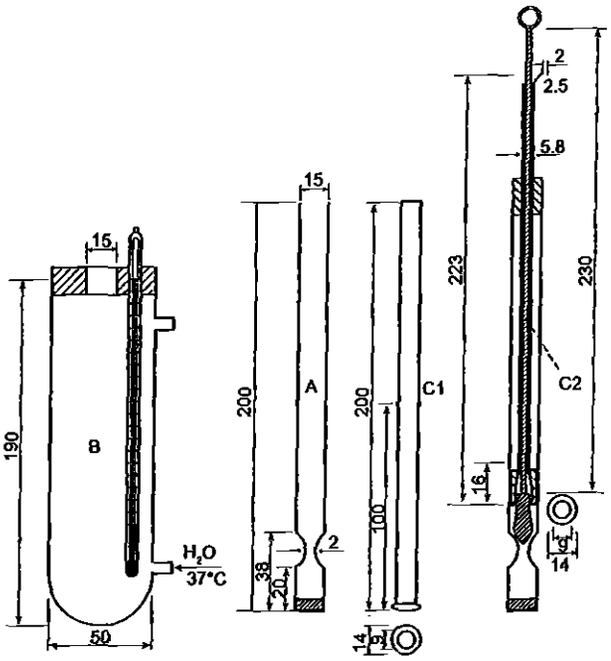

Figure 2.9.22.-2. – *Apparatus B for measuring the softening time of lipophilic suppositories*

Dimensions in millimetres

K. Pycnometric Density of Solids[1]

(Ph. Eur. method 2.9.23)

Gas pycnometric density is determined by measuring the volume occupied by a known mass of powder, which is equivalent to the volume of gas displaced by the powder using a gas displacement pycnometer. In gas pycnometric density measurements, the volume determined excludes the volume occupied by open pores; however, it includes the volume occupied by sealed pores or pores inaccessible to the gas.

Usually, helium is used as a test gas due to its high diffusivity into small open pores. If gases other than helium are used, different values would be obtained, since the penetration of the gas is dependent on the size of the pore as well as the cross-sectional area of the gas molecules.

The measured density is a volume-weighted average of the densities of individual powder particles. It is called the particle density, distinct from the true density of a solid or the bulk density of a powder. The density of solids is expressed in grams per cubic centimetre (g/cm^3), although the International Unit is the kilogram per cubic metre (1 g/cm^3 = 1000 kg/m^3).

APPARATUS

The apparatus (see Figure 2.9.23.-1) consists of the following:

— a sealed test cell, with empty cell volume V_c, connected through a valve to an expansion cell, with volume V_r;

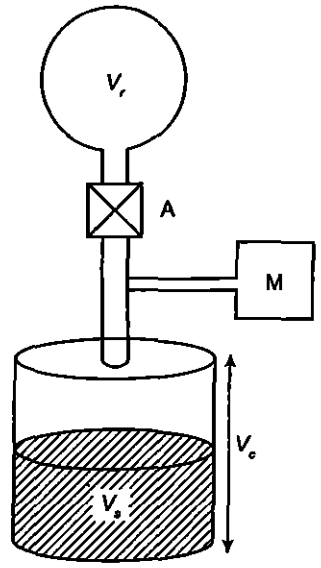
— a system capable of pressurising the test cell with the measurement gas until a defined pressure (P) indicated by a manometer;

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8. Pharmacopoeial harmonisation.*

— the system is connected to a source of measurement gas, preferably helium, unless another gas is specified.

The gas pycnometric density measurement is performed at a temperature between 15 °C and 30 °C that does not vary by more than 2 °C during the course of measurement.

The apparatus is calibrated, which means that the volumes V_c and V_r are determined using a suitable calibration standard whose volume is known to the nearest 0.001 cm^3. The procedure described below is followed in 2 runs, firstly with an empty test cell, and secondly with the calibration standard placed in the test cell. The volumes V_c and V_r are calculated using the equation for the sample volume (V_s), taking into account that V_s is zero in the first run.



A = valve;
V_r = expansion volume, in cubic centimetres;
V_c = cell volume, in cubic centimetres;
V_s = sample volume, in cubic centimetres;
M = manometer.

Figure 2.9.23.-1. – *Schematic diagram of a gas pycnometer*

METHOD

Volatile contaminants in the powder are removed by degassing the powder under a constant purge of helium prior to the measurement. Occasionally, powders may have to be degassed under vacuum. Because volatiles may be evolved during the measurement, weighing of the sample is carried out after the pycnometric measurement of volume.

Weigh the test cell of the pycnometer and record the mass. Fill the test cell with a given mass of powder of the substance to be examined. Seal the test cell in the pycnometer. Record the system reference pressure (P_r) as indicated by the manometer while the valve that connects the expansion cell with the test cell is open. Close the valve to separate the expansion cell from the test cell. Pressurise the test cell with the gas to an initial pressure (P_i) and record the value obtained. Open the valve to connect the expansion cell with the test cell. Record the final pressure (P_f). Repeat the measurement sequence for the same powder sample until consecutive measurements of the sample volume (V_s) agree to within 0.2 per cent. Unload the test cell and measure the final powder mass (m), expressed in grams. If the pycnometer differs in operation or construction from the one shown in Figure 2.9.23.-1, follow the instructions of the manufacturer of the pycnometer.

EXPRESSION OF THE RESULTS

The sample volume (V_s) is given by the equation:

$$V_s = V_c - \frac{V_r}{\frac{P_i - P_r}{P_f - P_r} - 1}$$

The density (ρ) is given by the equation:

$$\rho = \frac{m}{V_s}$$

The sample conditioning is indicated with the results. For example, indicate whether the sample was tested as is or dried under specific conditions such as those described for loss on drying.

M. Specific Surface Area by Gas Adsorption[1]

(Ph. Eur. method 2.9.26)

INTRODUCTION

The specific surface area of a powder is determined by physical adsorption of a gas on the surface of the solid and by calculating the amount of adsorbate gas corresponding to a monomolecular layer on the surface. Physical adsorption results from relatively weak forces (van der Waals forces) between the adsorbate gas molecules and the adsorbent surface of the test powder. The determination is usually carried out at the temperature of liquid nitrogen.

The amount of gas adsorbed can be measured by a volumetric or continuous flow procedure.

BRUNAUER, EMMETT AND TELLER (BET) THEORY AND SPECIFIC SURFACE AREA DETERMINATION

MULTI-POINT MEASUREMENT

The data are treated according to the Brunauer, Emmett and Teller (BET) adsorption isotherm equation:

$$\frac{1}{\left[V_a\left(\frac{P_o}{P} - 1\right)\right]} = \frac{C-1}{V_m C} \times \frac{P}{P_o} + \frac{1}{V_m C} \qquad (1)$$

P = partial vapour pressure of adsorbate gas in equilibrium with the surface at 77.4 K (b.p. of liquid nitrogen), in pascals,
P_o = saturated pressure of adsorbate gas, in pascals,
V_a = volume of gas adsorbed at standard temperature and pressure (STP) [273.15 K and atmospheric pressure (1.013×10^5 Pa)], in millilitres,
V_m = volume of gas adsorbed at STP to produce an apparent monolayer on the sample surface, in millilitres,
C = dimensionless constant that is related to the enthalpy of adsorption of the adsorbate gas on the powder sample.

A value of V_a is measured at each of not less than 3 values of P/P_o.

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

Then the BET value

$$\frac{1}{\left[V_a\left(\frac{P_o}{P}-1\right)\right]}$$

is plotted against P/P_o according to equation (1). This plot should yield a straight line usually in the approximate relative pressure range 0.05 to 0.3. The data are considered acceptable if the correlation coefficient, r, of the linear regression is not less than 0.9975; that is, r^2 is not less than 0.995. From the resulting linear plot, the slope, which is equal to $(C-1)/V_mC$, and the intercept, which is equal to $1/V_mC$, are evaluated by linear regression analysis. From these values, V_m is calculated as $1/(slope + intercept)$, while C is calculated as $(slope/intercept) + 1$. From the value of V_m so determined, the specific surface area, S, in $m^2 \cdot g^{-1}$, is calculated by the equation:

$$S = \frac{V_m N a}{m \times 22400} \quad (2)$$

N	=	Avogadro constant (6.022×10^{23} mol^{-1}),
a	=	effective cross-sectional area of one adsorbate molecule, in square metres (0.162 nm^2 for nitrogen and 0.195 nm^2 for krypton),
m	=	mass of test powder, in grams,
22400	=	volume occupied by 1 mole of the adsorbate gas at STP allowing for minor departures from the ideal, in millilitres.

A minimum of 3 data points is required. Additional measurements may be carried out, especially when non-linearity is obtained at a P/P_o value close to 0.3. Because non-linearity is often obtained at a P/P_o value below 0.05, values in this region are not recommended. The test for linearity, the treatment of the data, and the calculation of the specific surface area of the sample are described above.

SINGLE-POINT MEASUREMENT

Normally, at least 3 measurements of V_a each at different values of P/P_o are required for the determination of specific surface area by the dynamic flow gas adsorption technique (*Method I*) or by volumetric gas adsorption (*Method II*). However, under certain circumstances described below, it may be acceptable to determine the specific surface area of a powder from a single value of V_a measured at a single value of P/P_o such as 0.300 (corresponding to 0.300 mole of nitrogen or 0.001038 mole fraction of krypton), using the following equation for calculating V_m:

$$V_m = V_a\left(1-\frac{P}{P_o}\right) \quad (3)$$

The specific surface area is then calculated from the value of V_m by equation (2) given above.

The single-point method may be employed directly for a series of powder samples of a given material for which the material constant C is much greater than unity. These circumstances may be verified by comparing values of specific surface area determined by the single-point method with that determined by the multiple-point method for the series of powder samples. Close similarity between the single-point values and multiple-point values suggests that $1/C$ approaches zero.

The single-point method may be employed indirectly for a series of very similar powder samples of a given material for which the material constant C is not infinite but may be assumed to be invariant. Under these circumstances, the error associated with the single-point method can be reduced or eliminated by using the multiple-point method to evaluate C for one of the samples of the series from the BET plot, from which C is calculated as $(1 + slope/intercept)$. Then V_m is calculated from the single value of V_a measured at a single value of P/P_o by the equation:

$$V_m = V_a\left(\frac{P_o}{P}-1\right)\left[\frac{1}{C}+\frac{C-1}{C}\times\left(\frac{P}{P_o}\right)\right] \quad (4)$$

The specific surface area is calculated from V_m by equation (2) given above.

EXPERIMENTAL TECHNIQUES

This section describes the methods to be used for the sample preparation, the dynamic flow gas adsorption technique (*Method I*) and the volumetric gas adsorption technique (*Method II*).

SAMPLE PREPARATION

Outgassing

Before the specific surface area of the sample can be determined, it is necessary to remove gases and vapours that may have become physically adsorbed onto the surface after manufacture and during treatment, handling and storage. If outgassing is not achieved, the specific surface area may be reduced or may be variable because an intermediate area of the surface is covered with molecules of the previously adsorbed gases or vapours. The outgassing conditions are critical for obtaining the required precision and accuracy of specific surface area measurements on pharmaceuticals because of the sensitivity of the surface of the materials.

Conditions The outgassing conditions must be demonstrated to yield reproducible BET plots, a constant weight of test powder, and no detectable physical or chemical changes in the test powder.

The outgassing conditions defined by the temperature, pressure and time should be chosen so that the original surface of the solid is reproduced as closely as possible. Outgassing of many substances is often achieved by applying a vacuum, by purging the sample in a flowing stream of a non-reactive, dry gas, or by applying a desorption-adsorption cycling method. In either case, elevated temperatures are sometimes applied to increase the rate at which the contaminants leave the surface. Caution should be exercised when outgassing powder samples using elevated temperatures to avoid affecting the nature of the surface and the integrity of the sample.

If heating is employed, the recommended temperature and time of outgassing are as low as possible to achieve reproducible measurement of specific surface area in an acceptable time. For outgassing sensitive samples, other outgassing methods such as the desorption-adsorption cycling method may be employed.

Adsorbate

The standard technique is the adsorption of nitrogen of analytical quality at liquid nitrogen temperature.

For powders of low specific surface area (< 0.2 m$^2 \cdot$g^{-1}) the proportion adsorbed is low. In such cases the use of krypton at liquid nitrogen temperature is preferred because the low vapour pressure exerted by this gas greatly reduces error. The use of larger sample quantities where feasible (equivalent to 1 m^2 or greater total surface area using nitrogen) may compensate for the errors in determining low surface areas.

All gases used must be free from moisture.

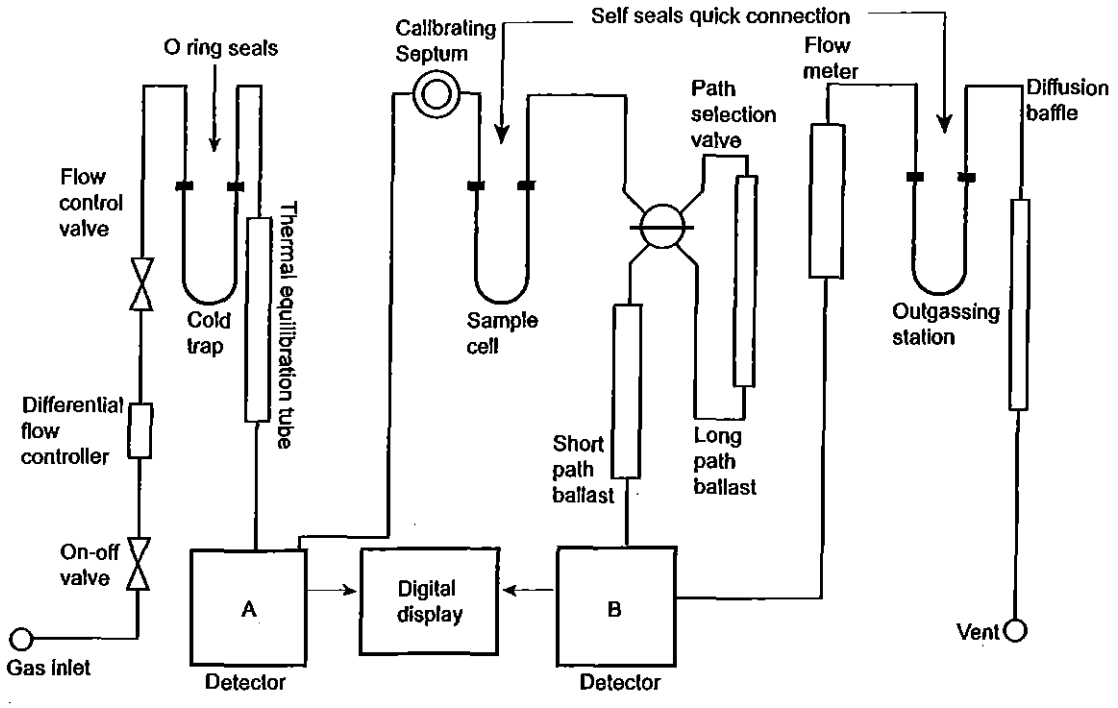


Figure 2.9.26.-1. – *Schematic diagram of the dynamic flow method apparatus*

Quantity of sample

Accurately weigh a quantity of the test powder such that the total surface of the sample is at least 1 m^2 when the adsorbate is nitrogen and 0.5 m^2 when the adsorbate is krypton.

Lower quantities of sample may be used after appropriate validation.

MEASUREMENTS

Because the amount of gas adsorbed under a given pressure tends to increase on decreasing the temperature, adsorption measurements are usually made at a low temperature. Measurement is performed at 77.4 K, the boiling point of liquid nitrogen.

Method I: the dynamic flow method

Principle

In the dynamic flow method (see Figure 2.9.26.-1), the recommended adsorbate gas is dry nitrogen or krypton, while helium is employed as a diluent gas, which is not adsorbed under the recommended conditions.

A minimum of 3 mixtures of the appropriate adsorbate gas with helium are required within the P/P_o range 0.05 to 0.30.

The gas detector-integrator should provide a signal that is approximately proportional to the volume of the gas passing through it under defined conditions of temperature and pressure. For this purpose, a thermal conductivity detector with an electronic integrator is one among various suitable types. A minimum of 3 data points within the recommended range of 0.05 to 0.30 for P/P_o is to be determined.

Procedure

A known mixture of the gases, usually nitrogen and helium, is passed through a thermal conductivity cell, through the sample, again through the thermal conductivity cell and then to a recording potentiometer.

Immerse the sample cell in liquid nitrogen, then the sample adsorbs nitrogen from the mobile phase. This unbalances the thermal conductivity cell, and a pulse is generated on a recorder chart.

Remove from the coolant; this gives a desorption peak equal in area and in the opposite direction to the adsorption peak. Since this is better defined than the adsorption peak, it is the one used for the determination.

To effect the calibration, inject a known quantity of adsorbate into the system, sufficient to give a peak of similar magnitude to the desorption peak and obtain the proportion of gas volume per unit peak area.

Use a nitrogen/helium mixture for a single-point determination and several such mixtures or premixing 2 streams of gas for a multiple-point determination.

Calculation is essentially the same as for the volumetric method.

Method II: the volumetric method

Principle

In the volumetric method (see Figure 2.9.26.-2), the recommended adsorbate gas is nitrogen which is admitted into the evacuated space above the previously outgassed powder sample to give a defined equilibrium pressure, P, of the gas. The use of a diluent gas, such as helium, is therefore unnecessary, although helium may be employed for other purposes, such as to measure the dead volume.

Since only pure adsorbate gas, instead of a gas mixture, is employed, interfering effects of thermal diffusion are avoided in this method.

Procedure

Admit a small amount of dry nitrogen into the sample tube to prevent contamination of the clean surface, remove the sample tube, insert the stopper, and weigh it. Calculate the weight of the sample. Attach the sample tube to the volumetric apparatus. Cautiously evacuate the sample down to the specified pressure (e.g. between 2 Pa and 10 Pa). Alternatively, some instruments operate by evacuating to a defined rate of pressure change (e.g. less than 13 Pa/30 s) and holding for a defined period of time before commencing the next step.

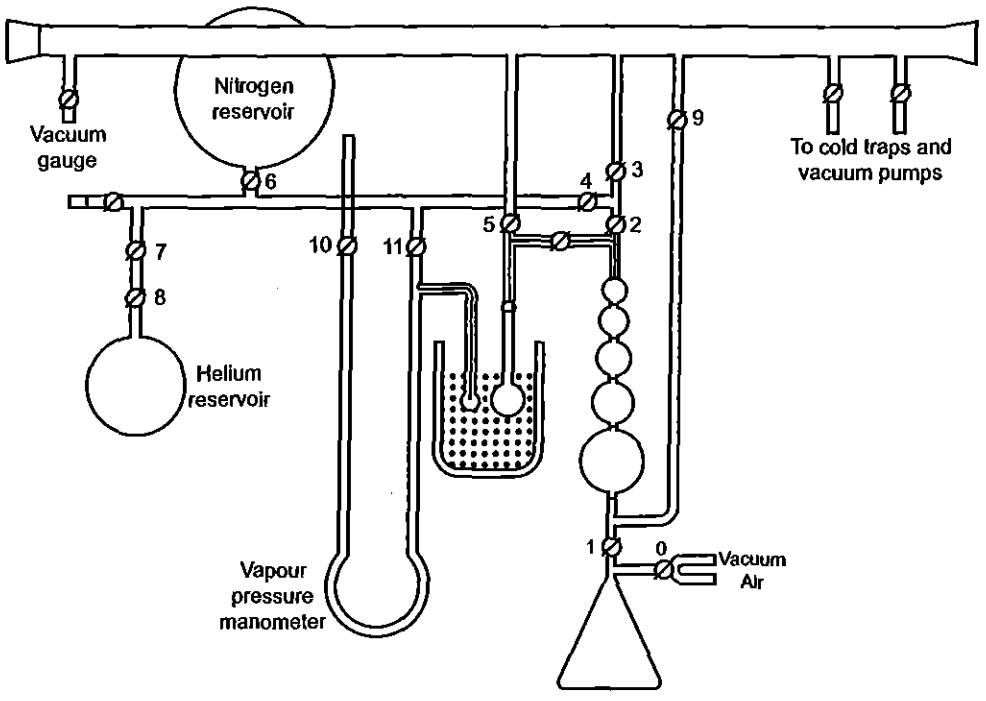

Figure 2.9.26.-2. – *Schematic diagram of the volumetric method apparatus*

If the principle of operation of the instrument requires the determination of the dead volume in the sample tube, for example, by the admission of a non-adsorbed gas, such as helium, this procedure is carried out at this point, followed by evacuation of the sample. The determination of dead volume may be avoided using difference measurements, that is, by means of reference and sample tubes connected by a differential transducer. The adsorption of nitrogen gas is then measured as described below.

Raise a Dewar vessel containing liquid nitrogen at 77.4 K up to a defined point on the sample cell. Admit a sufficient volume of adsorbate gas to give the lowest desired relative pressure. Measure the volume adsorbed, V_a. For multipoint measurements, repeat the measurement of V_a at successively higher P/P_o values. When nitrogen is used as the adsorbate gas, P/P_o values of 0.10, 0.20, and 0.30 are often suitable.

REFERENCE MATERIALS

Periodically verify the functioning of the apparatus using appropriate reference materials of known surface area, such as α-alumina, which should have a specific surface area similar to that of the sample to be examined.

N1. Powder Flow[1]

(Ph. Eur. method 2.9.36)

The widespread use of powders in the pharmaceutical industry has generated a variety of methods for characterising powder flow. Not surprisingly, scores of references appear in the pharmaceutical literature, attempting to correlate the various measures of powder flow to manufacturing properties. The development of such a variety of test methods was inevitable; powder behavior is multifaceted and thus complicates the effort to characterise powder flow.

The purpose of this chapter is to review the methods for characterising powder flow that have appeared most frequently in the pharmaceutical literature. In addition, while it is clear that no single and simple test method can adequately characterise the flow properties of pharmaceutical powders, this chapter proposes the standardisation of test methods that may be valuable during pharmaceutical development.

4 commonly reported methods for testing powder flow are:
— angle of repose,
— compressibility index or Hausner ratio,
— flow rate through an orifice,
— shear cell.

In addition, numerous variations of each of these basic methods are available. Given the number of test methods and variations, standardising the test methodology, where possible, would be advantageous.

With this goal in mind, the most frequently used methods are discussed below. Important experimental considerations are identified and recommendations are made regarding standardisation of the methods. In general, any method of measuring powder flow must be practical, useful, reproducible and sensitive, and must yield meaningful results. It bears repeating that no simple powder flow method will adequately or completely characterise the wide range of flow properties experienced in the pharmaceutical industry. An appropriate strategy may well be the use of multiple standardised test methods to characterise the various aspects of powder flow as needed by the pharmaceutical scientist.

ANGLE OF REPOSE

The angle of repose has been used in several branches of science to characterise the flow properties of solids. Angle of repose is a characteristic related to interparticulate friction, or resistance to movement between particles. Angle of repose test results are reported to be very dependent upon the method used. Experimental difficulties arise due to segregation of material and consolidation or aeration of the powder as the cone is formed. Despite its difficulties, the

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

method continues to be used in the pharmaceutical industry, and a number of examples demonstrating its value in predicting manufacturing problems appear in the literature.

The angle of repose is the constant, three-dimensional angle (relative to the horizontal base) assumed by a cone-like pile of material formed by any of several different methods, described briefly below.

Basic methods for angle of repose

A variety of angle of repose test methods are described in the literature. The most common methods for determining the static angle of repose can be classified based on 2 important experimental variables:

— the height of the 'funnel' through which the powder passes may be fixed relative to the base, or the height may be varied as the pile forms;
— the base upon which the pile forms may be of fixed diameter or the diameter of the powder cone may be allowed to vary as the pile forms.

Variations in angle of repose methods

Variations of the above methods have also been used to some extent in the pharmaceutical literature:

— *drained angle of repose*: this is determined by allowing an excess quantity of material positioned above a fixed diameter base to 'drain' from the container. Formation of a cone of powder on the fixed diameter base allows determination of the drained angle of repose;
— *dynamic angle of repose*: this is determined by filling a cylinder (with a clear, flat cover on one end) and rotating it at a specified speed. The dynamic angle of repose is the angle (relative to the horizontal) formed by the flowing powder. The internal angle of kinetic friction is defined by the plane separating those particles sliding down the top layer of the powder and those particles that are rotating with the drum (with roughened surface).

General scale of flowability for angle of repose

While there is some variation in the qualitative description of powder flow using the angle of repose, much of the pharmaceutical literature appears to be consistent with the classification by Carr[2], which is shown in Table 2.9.36.-1. There are examples in the literature of formulations with an angle of repose in the range of 40-50 degrees that manufactured satisfactorily. When the angle of repose exceeds 50 degrees, the flow is rarely acceptable for manufacturing purposes.

Table 2.9.36.-1. – *Flow properties and corresponding angles of repose*[2]

Flow property	Angle of repose (degrees)
Excellent	25-30
Good	31-35
Fair (aid not needed)	36-40
Passable (may hang up)	41-45
Poor (must agitate, vibrate)	46-55
Very poor	56-65
Very, very poor	> 66

Experimental considerations for angle of repose

Angle of repose is not an intrinsic property of the powder, that is to say, it is very much dependent upon the method used to form the cone of powder. On this subject, the existing literature raises these important considerations:

— the peak of the cone of powder can be distorted by the impact of powder from above. By carefully building the powder cone, the distortion caused by impact can be minimised;
— the nature of the base upon which the powder cone is formed influences the angle of repose. It is recommended that the powder cone be formed on a 'common base', which can be achieved by forming the cone of powder on a layer of powder. This can be done by using a base of fixed diameter with a protruding outer edge to retain a layer of powder upon which the cone is formed.

Recommended procedure for angle of repose

Form the angle of repose on a fixed base with a retaining lip to retain a layer of powder on the base. The base must be free of vibration. Vary the height of the funnel to carefully build up a symmetrical cone of powder. Care must be taken to prevent vibration as the funnel is moved. The funnel height is maintained at approximately 2-4 cm from the top of the powder pile as it is being formed in order to minimise the impact of falling powder on the tip of the cone. If a symmetrical cone of powder cannot be successfully or reproducibly prepared, this method is not appropriate. Determine the angle of repose by measuring the height of the cone of powder and calculating the angle of repose, α, from the following equation:

$$\tan(\alpha) = \frac{\text{height}}{0.5 \times \text{base}}$$

COMPRESSIBILITY INDEX AND HAUSNER RATIO

In recent years the compressibility index and the closely related Hausner ratio have become the simple, fast, and popular methods of predicting powder flow characteristics. The compressibility index has been proposed as an indirect measure of bulk density, size and shape, surface area, moisture content, and cohesiveness of materials, because all of these can influence the observed compressibility index. The compressibility index and the Hausner ratio are determined by measuring both the bulk volume and tapped volume of a powder.

Basic methods for compressibility index and Hausner ratio

While there are some variations in the method of determining the compressibility index and Hausner ratio, the basic procedure is to measure the unsettled apparent volume, (V_0), and the final tapped volume, (V_f), of the powder after tapping the material until no further volume changes occur. The compressibility index and the Hausner ratio are calculated as follows:

$$\textit{Compressibility Index} = 100 \times \frac{V_0 - V_f}{V_0}$$

$$\textit{Hausner Ratio} = \frac{V_0}{V_f}$$

Alternatively, the compressibility index and Hausner ratio may be calculated using measured values of bulk density (ρ_{bulk}) and tapped density (ρ_{tapped}) as follows:

$$\textit{Compressibility Index} = 100 \times \frac{\rho_{tapped} - \rho_{bulk}}{\rho_{tapped}}$$

$$\textit{Hausner Ratio} = \frac{\rho_{tapped}}{\rho_{bulk}}$$

[2] *Carr RL. Evaluating flow properties of solids. Chem. Eng 1965; 72:163-168.*

In a variation of these methods, the rate of consolidation is sometimes measured rather than, or in addition to, the change in volume that occurs on tapping. For the compressibility index and the Hausner ratio, the generally accepted scale of flowability is given in Table 2.9.36.-2.

Table 2.9.36.-2. – *Scale of flowability*[3]

Compressibility index (per cent)	Flow character	Hausner ratio
1-10	Excellent	1.00-1.11
11-15	Good	1.12-1.18
16-20	Fair	1.19-1.25
21-25	Passable	1.26-1.34
26-31	Poor	1.35-1.45
32-37	Very poor	1.46-1.59
> 38	Very, very poor	> 1.60

Experimental considerations for the compressibility index and Hausner ratio

Compressibility index and Hausner ratio are not intrinsic properties of the powder, that is to say, they are dependent upon the methodology used. The existing literature points out several important considerations affecting the determination of the unsettled apparent volume, V_0, of the final tapped volume, V_f, of the bulk density, ρ_{bulk}, and of the tapped density, ρ_{tapped}:

- the diameter of the cylinder used,
- the number of times the powder is tapped to achieve the tapped density,
- the mass of material used in the test,
- rotation of the sample during tapping.

Recommended procedure for compressibility index and Hausner ratio

Use a 250 mL volumetric cylinder with a test sample mass of 100 g. Smaller amounts and volumes may be used, but variations in the method must be described with the results. An average of 3 determinations is recommended.

FLOW THROUGH AN ORIFICE

The flow rate of a material depends upon many factors, some of which are particle-related and some related to the process. Monitoring the rate of flow of material through an orifice has been proposed as a better measure of powder flowability. Of particular significance is the utility of monitoring flow continuously, since pulsating flow patterns have been observed even for free-flowing materials. Changes in flow rate as the container empties can also be observed. Empirical equations relating flow rate to the diameter of the opening, particle size, and particle density have been determined. However, determining the flow rate through an orifice is useful only with free-flowing materials.

The flow rate through an orifice is generally measured as the mass per time flowing from any of a number of types of containers (cylinders, funnels, hoppers). Measurement of the flow rate can be in discrete increments or continuous.

Basic methods for flow through an orifice

There are a variety of methods described in the literature. The most common for determining the flow rate through an orifice can be classified based on 3 important experimental variables:

- the type of container used to contain the powder. Common containers are cylinders, funnels, and hoppers from production equipment;
- the size and shape of the orifice used. The orifice diameter and shape are critical factors in determining powder flow rate;
- the method of measuring powder flow rate. Flow rate can be measured continuously using an electronic balance with some sort of recording device (strip chart recorder, computer). It can also be measured in discrete samples (for example, the time it takes for 100 g of powder to pass through the orifice to the nearest tenth of a second or the amount of powder passing through the orifice in 10 s to the nearest tenth of a gram).

Variations in methods for flow through an orifice

Either mass flow rate or volume flow rate can be determined. Mass flow rate is the easier of the methods, but it biases the results in favour of high-density materials. Since die fill is volumetric, determining volume flow rate may be preferable. A vibrator is occasionally attached to facilitate flow from the container, however, this appears to complicate interpretation of results. A moving orifice device has been proposed to more closely simulate rotary press conditions. The minimum diameter orifice through which powder flows can also be identified.

General scale of flowability for flow through an orifice

No general scale is available because flow rate is critically dependent on the method used to measure it. Comparison between published results is difficult.

Experimental considerations for flow through an orifice

Flow rate through an orifice is not an intrinsic property of the powder. It is very much dependent upon the methodology used. The existing literature points out several important considerations affecting these methods:

- the diameter and shape of the orifice,
- the type of container material (metal, glass, plastic),
- the diameter and height of the powder bed.

Recommended procedure for flow through an orifice

Flow rate through an orifice can be used only for materials that have some capacity to flow. It is not useful for cohesive materials. Provided that the height of the powder bed (the 'head' of powder) is much greater than the diameter of the orifice, the flow rate is virtually independent of the powder head. It is advisable to use a cylinder as the container, because the walls of the container must have little effect on flow. This configuration results in flow rate being determined by the movement of powder over powder, rather than powder along the wall of the container. Powder flow rate often increases when the height of the powder column is less than twice the diameter of the column. The orifice must be circular and the cylinder must be free of vibration. General guidelines for dimensions of the cylinder are as follows:

- diameter of the opening greater than 6 times the diameter of the particles,
- diameter of the cylinder greater than twice the diameter of the opening.

Use of a hopper as the container may be appropriate and representative of flow in a production situation. It is not advisable to use a funnel, particularly one with a stem, because flow rate will be determined by the size and length of the stem as well as the friction between the stem and the powder. A truncated cone may be appropriate, but flow will be influenced by the powder-wall friction coefficient, thus, selection of an appropriate construction material is important.

For the opening in the cylinder, use a flat-faced bottom plate with the option to vary orifice diameter to provide maximum

[3] *Carr RL. Evaluating flow properties of solids. Chem. Eng 1965; 72:163-168.*

flexibility and better ensure a powder-over-powder flow pattern. Rate measurement can be either discrete or continuous. Continuous measurement using an electronic balance can more effectively detect momentary flow rate variations.

SHEAR CELL METHODS

In an effort to put powder flow studies and hopper design on a more fundamental basis, a variety of powder shear testers and methods that permit more thorough and precisely defined assessment of powder flow properties have been developed. Shear cell methodology has been used extensively in the study of pharmaceutical materials. From these methods, a wide variety of parameters can be obtained, including the yield loci representing the shear stress-shear strain relationship, the angle of internal friction, the unconfined yield strength, the tensile strength, and a variety of derived parameters such as the flow factor and other flowability indices. Because of the ability to control experimental parameters more precisely, flow properties can also be determined as a function of consolidation load, time, and other environmental conditions. These methods have been successfully used to determine critical hopper and bin parameters.

Basic methods for shear cell

One type of shear cell is the cylindrical shear cell which is split horizontally, forming a shear plane between the lower stationary base and the upper moveable portion of the shear cell ring. After powder bed consolidation in the shear cell (using a well-defined procedure), the force necessary to shear the powder bed by moving the upper ring is determined. Annular shear cell designs offer some advantages over the cylindrical shear cell design, including the need for less material. A disadvantage, however, is that because of its design, the powder bed is not sheared as uniformly because material on the outside of the annulus is sheared more than material in the inner region. A third type of shear cell (plate-type) consists of a thin sandwich of powder between a lower stationary rough surface and an upper rough surface that is moveable.

All of the shear cell methods have their advantages and disadvantages, but a detailed review is beyond the scope of this chapter. As with the other methods for characterising powder flow, many variations are described in the literature. A significant advantage of shear cell methodology in general is a greater degree of experimental control. The methodology generally is rather time-consuming and requires significant amounts of material and a well-trained operator.

Recommendations for shear cell

The many existing shear cell configurations and test methods provide a wealth of data and can be used very effectively to characterise powder flow. They are also helpful in the design of equipment such as hoppers and bins. Because of the diversity of available equipment and experimental procedures, no specific recommendations regarding methodology are presented in this chapter. It is recommended that the results of powder flow characterisation using shear cell methodology include a complete description of equipment and methodology used.

N2. Powder Flow Properties by Shear Cell Methods

(Ph. Eur. method 2.9.49)

The methodology in this general chapter is based on standard test methods ASTM D6773-08 and ASTM D6128-14.

Powder flow properties play an important role in the design of formulations, processes and pharmaceutical production equipment, and an approach commonly used to characterise these properties is to submit the powder to shear tests, which are experiments designed to determine the flow properties of the powder by applying different states of stress and strain to it. Using these tests, a wide variety of parameters describing the flow properties of a powder can be studied, including the yield locus, the angle of internal friction, the compressive strength, the tensile strength, and a variety of derived parameters such as the flowability ratio. Because of the ability to control experimental parameters precisely, flow properties can also be determined as a function of consolidation load, time, and environmental conditions such as temperature and humidity.

Many suitable shear cell configurations and test methods are available; the most widely used are those based on the Jenike-type shear cell or on ring shear cells such as the Schulze-type ring shear tester.

PRINCIPLE

UNIAXIAL COMPRESSION TEST

The uniaxial compression test illustrates the concept of flowability. As shown in Figure 2.9.49.-1, a hollow cylinder (cross-sectional area A, internal wall assumed as frictionless) is filled with a powder. The powder is loaded by the consolidation stress (σ_1) in the vertical direction. The more the volume of the powder can be reduced, the more compressible the powder is. In addition to the increase in bulk density (ρ_b) from the consolidation stress, an increase in the strength of the powder is also observed. Hence, the powder is both consolidated and compressed through the effect of the consolidation stress.

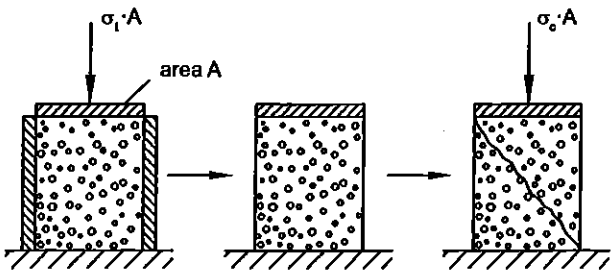

Figure 2.9.49.-1. – *Uniaxial compression test*

After consolidation, the powder is relieved of the consolidation stress (σ_1) and the hollow cylinder is removed. The consolidated cylindrical powder sample is subsequently loaded with an increasing vertical compressive stress and, at a certain stress, the sample fails along the shear plane and the powder starts to flow. The compressive strength (σ_c), or unconfined yield strength, is defined as the stress causing failure. Since the powder fails only at a sufficiently large vertical stress, there is a specific yield limit for the powder.

The yield limit of a powder is dependent on its stress history, i.e. its previous consolidation. The greater the consolidation stress (σ_1) the greater the bulk density (ρ_b) and compressive strength (σ_c). Thus, uniaxial compression tests conducted at different consolidation stresses (σ_1) yield different pairs of values (σ_1, σ_c) and (σ_1, ρ_b). Plotting these pairs of values as points in a (σ_1, σ_c) diagram and a (σ_1, ρ_b) diagram, respectively, and drawing in each diagram a curve through these points, usually results in curves similar to those shown for product A in Figure 2.9.49.-2, where bulk density (ρ_b) and compressive strength (σ_c) typically increase with consolidation stress (σ_1). Very rarely a progressive slope similar to that of the left part of curve B is observed. The graph of σ_c versus σ_1 is called the flow function.

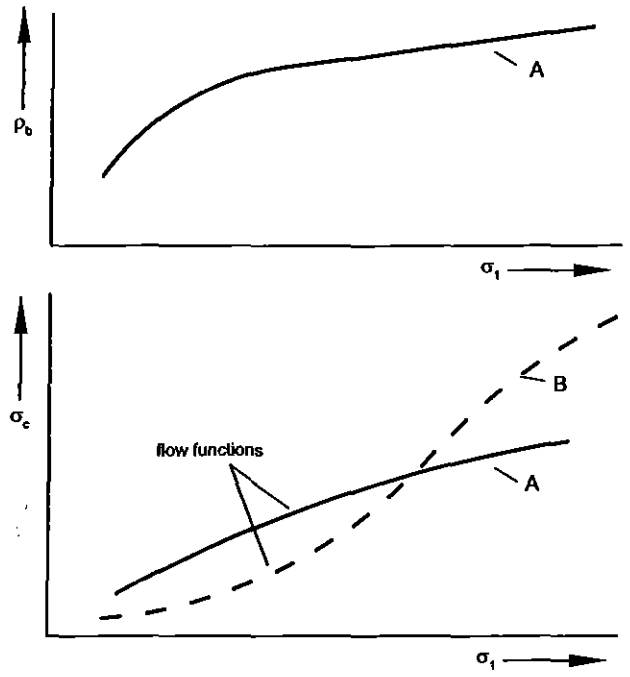

Figure 2.9.49.-2. – *Bulk density (ρ_b) and compressive strength (σ_c) as a function of consolidation stress (σ_1)*

NUMERICAL CHARACTERISATION OF FLOWABILITY

The flow function can be used to characterise the flow behaviour of a powder in terms of the flowability ratio (ff_c), which is given by:

$$ff_c = \sigma_1 / \sigma_c$$

The larger the ff_c, the better a powder flows. The ff_c value can be used to classify the flow behaviour as follows:

$ff_c < 1$	not flowing
$1 < ff_c < 2$	very cohesive
$2 < ff_c < 4$	cohesive
$4 < ff_c < 10$	easy-flowing
$10 < ff_c$	free-flowing

Figure 2.9.49.-3 shows the flow function A taken from the (σ_1, σ_c) diagram in Figure 2.9.49.-2. Additionally, the boundaries of the ranges of the classifications listed above are shown as straight lines, each representing a constant value of the flowability ratio (ff_c). This diagram clearly shows that the flowability ratio (ff_c) of a specific powder is dependent on the consolidation stress (σ_1) applied.

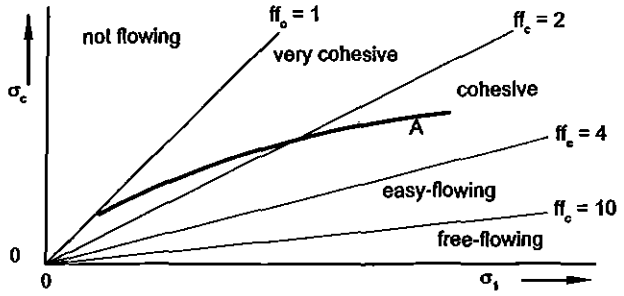

Figure 2.9.49.-3. – *Flow function and lines of constant flowability ratio*

Furthermore, the flow function may change depending on the consolidation time, for example, at the same σ_1 level, higher σ_c values may be obtained with longer consolidation times; this is known as the time consolidation effect. Possible mechanisms are solid or liquid bridges, solid crystallisation, viscoelastic or viscoplastic deformation, or chemical reactions at the particle contacts.

YIELD LIMIT AND MOHR STRESS CIRCLE

Assuming that the force of gravity and wall friction effects can be disregarded, the uniaxial compression test can be represented as shown in Figure 2.9.49.-4, in a (σ, τ) diagram where σ is the normal stress and τ is the shear stress. In such a diagram, all pairs of values (σ, τ) form a circle representing the stresses in the powder; this is called a 'Mohr stress circle'. The Mohr stress circle is centred on the sigma axis. The two intersect points with the sigma axis are called the minor and major principal stresses. Figure 2.9.49.-4 shows the Mohr stress circles corresponding to the uniaxial compression test and a possible yield limit of the sample (the real course of the yield limit cannot be determined with only the uniaxial compression test).

Mohr stress circle A describes the stresses in the powder sample at consolidation. Since no shear stress is applied, σ_1 corresponds to the normal stress or vertical stress (σ_v) and σ_2 corresponds to the horizontal stress (σ_h).

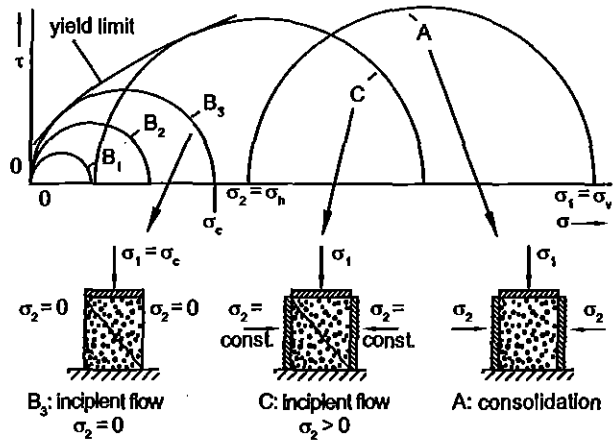

Figure 2.9.49.-4. – *Measurement of compressive strength and corresponding (σ, τ) diagram*

In the second part of the test shown in Figure 2.9.49.-1, the sample is loaded with increasing vertical stress after it has been relieved of the consolidation stress and the hollow cylinder has been removed. As the vertical load increases, the stress states at different load steps are represented by stress circles with increasing diameter (stress circles B_1, B_2, B_3 in Figure 2.9.49.-4). The minor principal stress, i.e. the horizontal stress, is equal to zero for all stress circles since the lateral surface of the sample is uncovered and not loaded.

Mohr stress circle B_3 represents the stresses in the powder sample at failure of the sample. Since the load corresponding to this Mohr stress circle causes incipient flow of the sample, Mohr stress circle B_3 must be tangential to the yield limit in the (σ, τ) diagram.

If, during the second part of the experiment shown in Figure 2.9.49.-1 (i.e. the measurement of compressive strength), a constant horizontal stress $\sigma_h > 0$ were also applied to the sample in addition to the vertical stress (σ_v), stress circles that indicate failure of the sample and are tangential to the yield limit (e.g. stress circle C in Figure 2.9.49.-4) would likewise be found. Thus the yield limit is

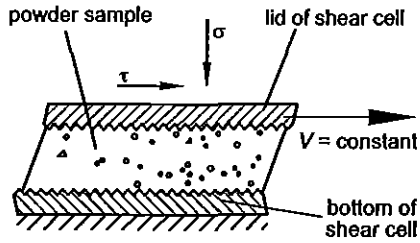

Figure 2.9.49.-5. – *Principle of shear deformation in a shear cell*

the envelope of all stress circles that indicate failure of a powder sample.

MEASUREMENT WITH A SHEAR TESTER

PRINCIPLE

The test sample must be representative of the powder with respect to particle-size distribution, moisture, temperature and other properties that may have an influence on the flow behaviour. The test sample is filled into a shear cell of circular or annular cross-section, depending on the type of tester used. In order to achieve a homogenous and representative powder bed, filling should be carried out uniformly in small horizontal layers using a spoon or spatula, without applying force to the surface of the material, until the cell is slightly overfilled. Excess powder is then removed by scraping off with a blade until the powder is flush with the top of the shear cell. The shear cell is then completed with a lid placed on top of the sample. The latter step may vary with the type of apparatus and is therefore carried out according to the manufacturer's instructions to achieve a homogenous and representative powder bed.

In general, a shear test measures the yield limit of a consolidated powder bed. This yield limit is also called the yield locus. It depends to a certain extent on the apparatus and experimental conditions. Typically the yield locus is measured immediately after consolidation of the powder bed. If however the yield locus is measured after a certain consolidation time, then it is called the time yield locus. When running a shear test, a normal stress (σ) is applied vertically to the powder in the shear cell. A shear deformation of the sample is then induced by moving the lid of the shear cell relative to the bottom of the shear cell in a horizontal direction with constant velocity (V) (see Figure 2.9.49.-5). This results in a horizontal shear stress (τ), which develops due to the friction between the particles in the shearing plane. The lid of the shear cell is allowed to move vertically in order to adjust to changes in the sample's bulk density.

When a point of a yield locus is measured, as in the uniaxial compression test, 2 steps are necessary: first the powder sample is consolidated in a preshear step, and then a point of the yield locus is measured in a shear or shear-to-failure step.

PRESHEAR STEP

For preshear, the powder sample is loaded in the vertical direction under a well-defined normal stress ($\sigma = \sigma_{pre}$), and is then sheared. Preshear is stopped when steady-state flow, characterised by constant shear stress (τ_{pre}), is achieved.

The pair of values of normal stress and shear stress at steady-state flow (σ_{pre}, τ_{pre}) is plotted in a normal stress - shear stress diagram ((σ, τ) diagram, Figure 2.9.49.-6, right). Point (σ_{pre}, τ_{pre}) is called the preshear point.

SHEAR-TO-FAILURE STEP

After the powder has been consolidated by the preshear procedure, the shear stress (τ) is reduced to zero by reversing the relative motion of the lid with respect to the bottom of the shear cell.

For the next step of the test procedure, the so-called shear or shear-to-failure step, the normal stress acting on the sample is decreased to a value σ_{sh}, which is less than the normal stress at preshear (σ_{pre}).

If the consolidated sample is sheared under the normal stress $\sigma_{sh} < \sigma_{pre}$, it will start to flow when a sufficiently large shear stress (τ_{sh}) is attained. At that point particles start to move against each other. The material will start to dilate, i.e. decrease in bulk density and shear resistance, and thus shear stress will decrease. The maximum shear stress (τ_{sh}) characterises incipient flow. The corresponding pair of values (σ_{sh}, τ_{sh}) is a point of the yield locus in the (σ, τ) diagram (Figure 2.9.49.-6, right). Such a point is called a shear point or a point of incipient flow.

In order to measure the course of the yield locus, several of the tests described above must be performed, where the samples must first be consolidated at the same normal stress (σ_{pre}, preshear). Then the samples are sheared to failure under different normal stresses $\sigma_{sh} < \sigma_{pre}$. The yield locus follows a curve plotted through all measured shear points (Figure 2.9.49.-6, right). In general, at least 3 shear points should be measured.

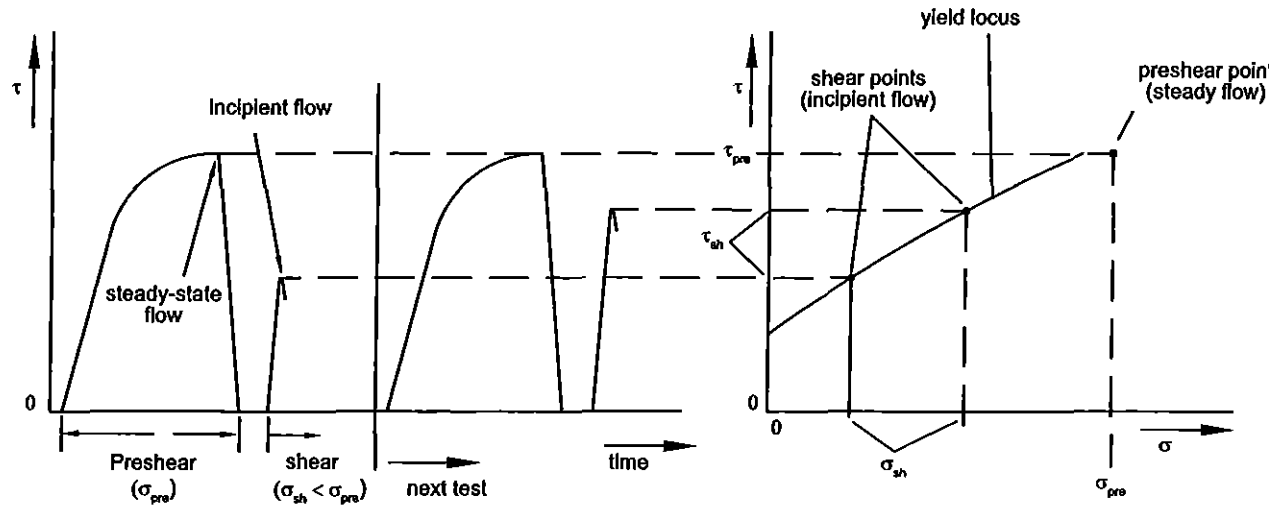

Figure 2.9.49.-6. – *Plot of shear stress versus time (left) and corresponding yield locus (right)*

With the Jenike-type shear cell a new sample has to be prepared for each shear point (indicated as 'next test' in Figure 2.9.49.-6). However, with ring shear testers a complete yield locus is usually measured with 1 sample. In addition, with the Schulze-type ring shear tester the bulk density is measured during the test, depending on the consolidation stress applied.

DATA EVALUATION

Parameters that describe the flow properties can be determined from the yield locus as shown in Figure 2.9.49.-7.

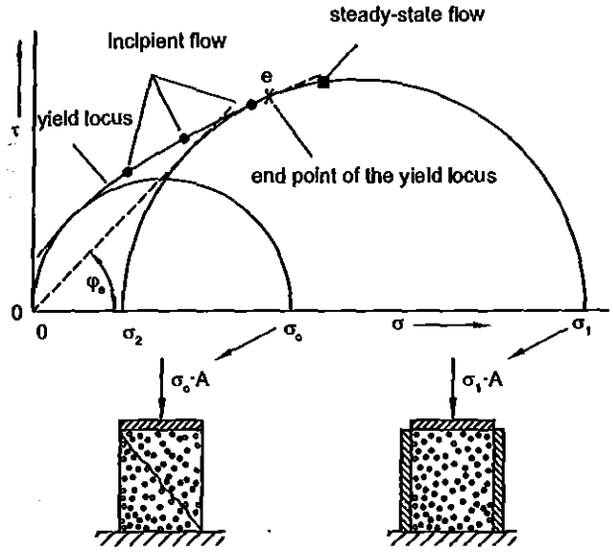

Figure 2.9.49.-7. – *Yield locus, Mohr stress circles and analogy with uniaxial compression test*

The consolidation stress (σ_1) is equal to the major principal stress of the Mohr stress circle, which is tangential to the yield locus, and intersects at the point of steady-state flow (σ_{pre}, τ_{pre}). This stress circle represents the stress distribution in the sample at the end of the consolidation procedure (stresses at steady-state flow). It corresponds to the stress circle at the end of consolidation in the uniaxial compression test.

The compressive strength (σ_c) is determined from the stress circle that is tangential to the yield locus and runs through the origin (minor principal stress $\sigma_2 = 0$). This stress circle represents a similar stress state to the one that prevails in the second step of the uniaxial compression test.

A straight line through the origin of the (σ, τ) diagram, tangent to the greater Mohr circle, is the effective yield locus, shown as a broken line in Figure 2.9.49.-7. It encloses the σ-axis with the effective angle of internal friction (φ_e). Because the largest Mohr stress circle indicates a state of steady-state flow, the angle φ_e can be regarded as a measure of the internal friction at steady-state flow.

Further flow properties can be determined from the yield locus as illustrated in Figure 2.9.49.-8.

For many applications the yield locus is linearised as the tangent to both Mohr circles. The linearised yield locus is characterised by its slope angle φ_{lin}.

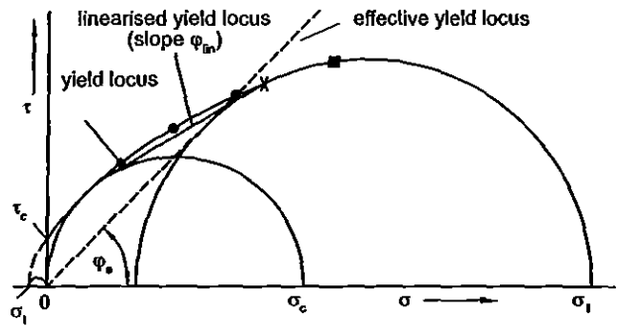

Figure 2.9.49.-8. – *Yield locus and characteristic values for flow properties*

The cohesion (τ_c) is the value of the shear stress where the yield locus intersects with the τ-axis, i.e. at normal stress $\sigma = 0$. The uniaxial tensile strength (σ_t) is the normal stress at the left end of the yield locus at shear stress $\tau = 0$. As it is difficult to measure the yield locus at small and negative stress levels, cohesion may be obtained by extrapolating the yield locus to the intersection with the τ-axis. Due to the pronounced non-linearity of the yield locus at low stresses, the cohesion obtained in this way is less accurate than the compressive strength, and it is hardly possible to determine tensile strength by extrapolation.

If several yield loci are measured at different stress levels, i.e. with different normal stresses at preshear (σ_{pre}), each yield locus represents another state of consolidation and another bulk density. The above-mentioned flow properties, namely compressive strength, effective angle of internal friction or slope angle of the linearised yield locus, can be indicated as functions of the consolidation stress (σ_1), similar to Figure 2.9.49.-2 where bulk density and compressive strength are plotted versus consolidation stress.

01. Optical Microscopy[1]

(Ph. Eur. method 2.9.37)

Optical microscopy for particle characterisation can generally be applied to particles of 1 µm and greater. The lower limit is imposed by the resolving power of the microscope. The upper limit is less definite and is determined by the increased difficulty associated with the characterisation of larger particles. Various alternative techniques are available for particle characterisation outside the applicable range of optical microscopy. Optical microscopy is particularly useful for characterising particles that are not spherical. This method may also serve as a base for the calibration of faster and more routine methods that may be developed.

Apparatus

Use a microscope that is stable and protected from vibration. The microscope magnification (product of the objective magnification, ocular magnification, and additional magnifying components) must be sufficient to allow adequate characterisation of the smallest particles to be classified in the test sample. The greatest numerical aperture of the objective is sought for each magnification range. Polarising filters may be used in conjunction with suitable analysers and retardation plates. Colour filters of relatively narrow spectral transmission are used with achromatic objectives, and are

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8 Pharmacopoeial harmonisation.*

preferable with apochromats; they are required for appropriate colour rendition in photomicrography. Condensers, corrected at least for spherical aberration are used in the microscope substage and with the lamp. The numerical aperture of the substage condenser matches that of the objective under the conditions of use; this is affected by the actual aperture of the condenser diaphragm and the presence of immersion oils.

Adjustment
The precise alignment of all elements of the optical system and proper focusing are essential. The focusing of the elements is done in accordance with the recommendations of the microscope manufacturer. Critical axial alignment is recommended.

Illumination
A requirement for good illumination is a uniform and adjustable intensity of light over the entire field of view; Köhler illumination is preferred. With coloured particles, choose the colour of the filters so as to control the contrast and detail of the image.

Visual characterisation
The magnification and numerical aperture must be sufficiently high to allow adequate resolution of the images of the particles to be characterised. Determine the actual magnification using a calibrated stage micrometer to calibrate an ocular micrometer. Errors can be minimised if the magnification is sufficient that the image of the particle is at least 10 ocular divisions. Each objective must be calibrated separately. To calibrate the ocular scale, the stage micrometer scale and the ocular scale must be aligned. In this way, a precise determination of the distance between ocular stage divisions can be made. Several different magnifications may be necessary to characterise materials having a wide particle size distribution.

Photographic characterisation
If particle size is to be determined by photographic methods, take care to ensure that the object is sharply focused at the plane of the photographic emulsion. Determine the actual magnification by photographing a calibrated stage micrometer, using photographic film of sufficient speed, resolving power, and contrast. Exposure and processing must be identical for photographs of both the test sample and the determination of magnification. The apparent size of a photographic image is influenced by the exposure, development, and printing processes as well as by the resolving power of the microscope.

Preparation of the mount
The mounting medium will vary according to the physical properties of the test sample. Sufficient, but not excessive, contrast between the sample and the mounting medium is required to ensure adequate detail of the sample edge. The particles must rest in one plane and be adequately dispersed to distinguish individual particles of interest. Furthermore, the particles must be representative of the distribution of sizes in the material and must not be altered during preparation of the mount. Care must be taken to ensure that this important requirement is met. Selection of the mounting medium must include a consideration of the analyte solubility.

Crystallinity characterisation
The crystallinity of a material may be characterised to determine compliance with the crystallinity requirement where stated in the individual monograph of a drug substance. Unless otherwise specified in the individual monograph, mount a few particles of the sample in mineral oil on a clean glass slide. Examine the mixture using a polarising microscope: the particles show birefringence (interference colors) and extinction positions when the microscope stage is revolved.

Limit test of particle size by microscopy
Weigh a suitable quantity of the powder to be examined (for example, 10-100 mg), and suspend it in 10 mL of a suitable medium in which the powder does not dissolve, adding, if necessary, a wetting agent. A homogeneous suspension of particles can be maintained by suspending the particles in a medium of similar or matching density and by providing adequate agitation. Introduce a portion of the homogeneous suspension into a suitable counting cell, and scan under a microscope an area corresponding to not less than 10 µg of the powder to be examined. Count all the particles having a maximum dimension greater than the prescribed size limit. The size limit and the permitted number of particles exceeding the limit are defined for each substance.

Particle size characterisation
The measurement of particle size varies in complexity depending on the shape of the particle, and the number of particles characterised must be sufficient to ensure an acceptable level of uncertainty in the measured parameters. Additional information on particle size measurement, sample size, and data analysis is available, for example, in ISO 9276. For spherical particles, size is defined by the diameter. For irregular particles, a variety of definitions of particle size exist. In general, for irregularly shaped particles, characterisation of particle size must also include information on the type of diameter measured as well as information on particle shape. Several commonly used measurements of particle size are defined in Figure 2.9.37.-1.

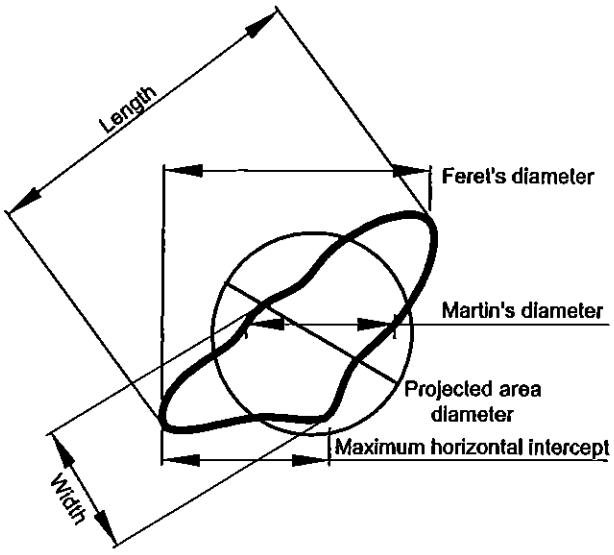

Figure 2.9.37.-1. – *Commonly used measurements of particle size*

- *Feret's diameter*: the distance between imaginary parallel lines tangent to a randomly oriented particle and perpendicular to the ocular scale,
- *Martin's diameter*: the diameter of the particle at the point that divides a randomly oriented particle into 2 equal projected areas,
- *projected area diameter*: the diameter of a circle that has the same projected area as the particle,
- *length*: the longest dimension from edge to edge of a particle oriented parallel to the ocular scale,
- *width*: the longest dimension of the particle measured at right angles to the length.

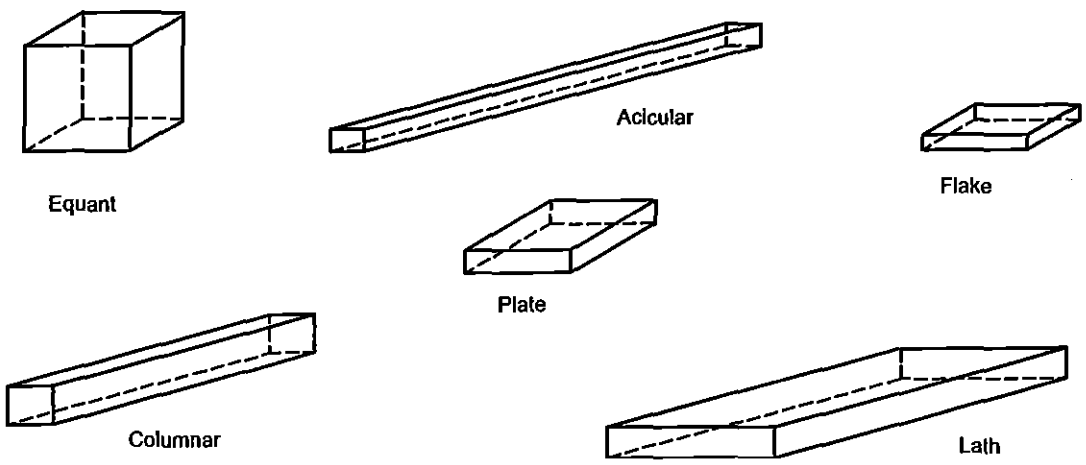

Figure 2.9.37.-2. – *Commonly used descriptions of particle shape*

Particle shape characterisation

For irregularly shaped particles, characterisation of particle size must also include information on particle shape. The homogeneity of the powder must be checked using appropriate magnification. The following defines some commonly used descriptors of particle shape (see Figure 2.9.37.-2).

— *acicular*: slender, needle-like particle of similar width and thickness,
— *columnar*: long, thin particle with a width and thickness that are greater than those of an acicular particle,
— *flake*: thin, flat particle of similar length and width,
— *plate*: flat particle of similar length and width but with greater thickness than a flake particle,
— *lath*: long, thin, blade-like particle,
— *equant*: particle of similar length, width, and thickness; both cubical and spherical particles are included.

General observations

A particle is generally considered to be the smallest discrete unit. A particle may be a liquid or semi-solid droplet; a single crystal or polycrystalline; amorphous or an agglomerate. Particles may be associated. This degree of association may be described by the following terms:

— *lamellar*: stacked plates,
— *aggregate*: mass of adhered particles,
— *agglomerate*: fused or cemented particles,
— *conglomerate*: mixture of 2 or more types of particles,
— *spherulite*: radial cluster,
— *drusy*: particle covered with tiny particles.

Particle condition may be described by the following terms:

— *edges*: angular, rounded, smooth, sharp, fractured,
— *optical*: color (using proper color balancing filters), transparent, translucent, opaque,
— *defects*: occlusions, inclusions.

Surface characteristics may be described as:

— *cracked*: partial split, break, or fissure,
— *smooth*: free of irregularities, roughness, or projections,
— *porous*: having openings or passageways,
— *rough*: bumpy, uneven, not smooth,
— *pitted*: small indentations.

O2. Scanning Electron Microscopy

(Ph. Eur. method 2.9.52)

This general chapter focuses on scanning electron microscopy applied to pharmaceutical materials, from research to quality control.

Scanning electron microscopy (SEM) is a powerful imaging technique that is superior to and complements light microscopy in terms of resolution, magnification and depth of field.

In addition, by exploiting the different interactions between the electrons and the specimen, it provides topographical and compositional information and can thus also be used as an analytical tool. When it is combined with elemental X-ray microanalysis, in particular, chemical analysis can be performed (see general chapter *2.2.37. X-ray fluorescence spectrometry*).

SEM is a well-established technique and, increasingly, it is being applied to examine and characterise a wide range of pharmaceutical materials in solid form but also, with the use of specialised specimen preparation methods, in semi-solid and liquid form.

PRINCIPLE

To produce magnified images, a scanning electron microscope uses a finely-focused beam of accelerated electrons instead of light; the specimen is scanned (rastered) in a rectangular pattern with the electron beam. This technique exploits the interactions between the electron beam and the specimen using different types of detectors. Due to the nature of these interactions, a variety of signals are produced and these can be used to provide characteristic information about the specimen at and from just below its surface.

INTERACTION WITH THE SPECIMEN

As the surface of the specimen is scanned by the electron beam, these electrons (also known as primary electrons) interact with the specimen and can penetrate to a depth of up to a few tens of micrometres. Electrons are scattered and absorbed within a teardrop-shaped volume just below the surface of the specimen, known as the interaction volume (Figure 2.9.52-1). The depth to which the electron beam penetrates is directly proportional to the beam voltage (a high-energy beam will penetrate deeper than a low-energy beam) and inversely proportional to the average atomic number of the constituent elements of the specimen (the beam will penetrate much deeper into a specimen rich in light elements than into one rich in heavy elements).

Types of emitted signals

Figure 2.9.52-1 illustrates the sources of the principal emitted signals, which are described as follows:

— *secondary electrons* are low-energy electrons that are ejected from just below the specimen surface as a result of the inelastic scattering of the incident electrons;
— *backscattered electrons* are high-energy electrons that result from the elastic scattering of incident electrons deeper in

the interaction volume; as a consequence, backscattered electron images typically have a lower spatial resolution than secondary electron images and show less surface detail;
— characteristic *X-rays* are produced when the incident electron beam interacts with the elements in the specimen;
— *cathodoluminescence* is the emission of photons in the visible spectrum when atoms and molecules deep within the interaction volume return to their ground state after being excited by the electron beam.

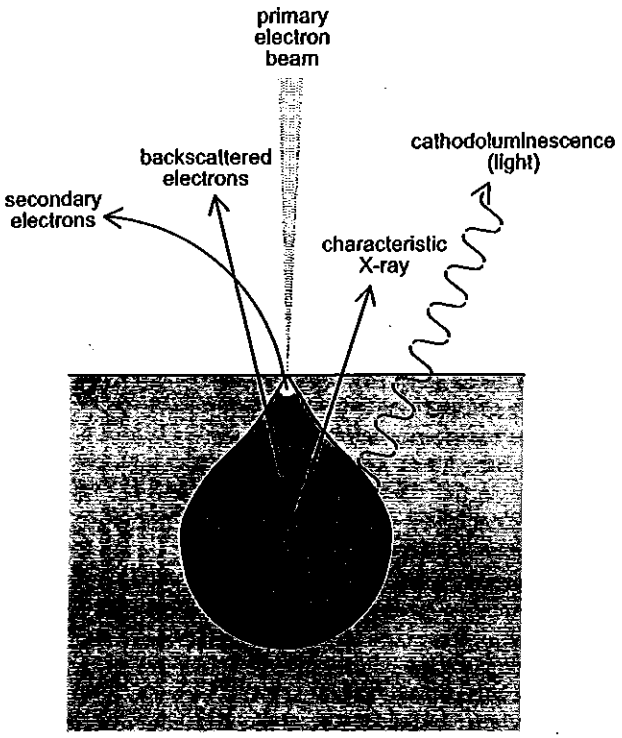

Figure 2.9.52-1. – *Schematic diagram showing the signals generated from a teardrop-shaped interaction volume*

APPLICATIONS

SEM is used to support many pharmaceutical processes during the formulation and analytical development, manufacturing and quality control of medicinal products. Its applications include:
— physical and chemical analysis of samples;
— comparison of raw materials from different suppliers;
— support for the development of particle sizing methods;
— particle size analysis (using image analysis);
— characterisation of the surface roughness of tablet film coatings;
— investigation of complaints;
— analysis and identification of particulate matter contamination;
— trouble-shooting of manufacturing problems;
— examination of falsified products.

SEM is used to examine a wide range of materials, such as active pharmaceutical ingredients (APIs), excipients, powder blends, solid dosage forms, medical devices, primary and secondary packaging materials and contaminants.
The examination of SEM images permits the qualitative and quantitative assessment of the homogeneity and consistency of powders as raw materials or after processing (e.g. compressed into tablets), with respect to the shapes, sizes and size distributions of particles in powders and of the texture, porosity and shapes of the crystals. This information can be correlated with dissolution behaviour, bioavailability and the crystallinity of the components in solid dosage forms. SEM has particular value in supporting the development and optimisation of manufacturing processes for most solid dosage forms, such as tablets, powder mixtures for oral suspensions, granules, powders for inhalation, spray- or freeze-dried powders, and powders for injections.

SPECIFICITIES OF THE TECHNIQUE

SEM offers many distinct advantages over conventional optical light microscopy because specimens can be examined at higher magnifications (250 000 × compared to 1000 ×, for example) with greater lateral resolution (3 nm or better compared to about 200 nm) and superior depths of field. However, the interaction between the electrons and the specimen could induce a strong charging effect due to the accumulation of electrical charge on its surface. Specific preparation procedures may thus be required for non-conducting specimens so that the accumulated charges can be dissipated.

Therefore, the ultimate performance of an electron microscope depends upon a number of factors, with the nature of the specimen having a major influence on the quality of the final image.

EQUIPMENT

Figure 2.9.52-2 is a schematic diagram of an electron microscope. It typically consists of:

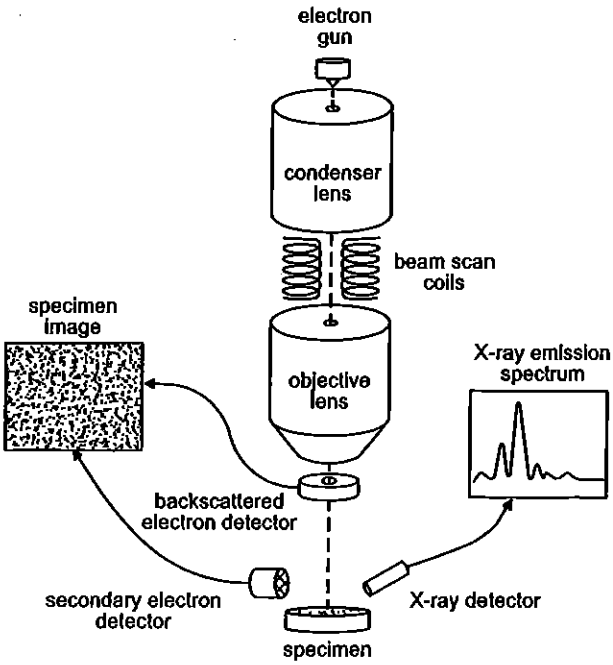

Figure 2.9.52-2. – *Schematic diagram of a scanning electron microscope*

— an electron gun that is housed at the top of an electron-optical column (electron column) and emits a beam of electrons; the electrons are accelerated down the column under the influence of a high voltage that is typically variable from 100 V to 30 kV;
— an electron column, which contains various components used to control and focus the electron beam:
  — a condenser lens system that controls the diameter and energy of the electron beam;
  — scan coils that are used to move the beam in a raster-fashion across a rectangular area on the specimen;

— an objective lens that focuses the beam to a fine point and directs it towards the specimen;
— a specimen chamber positioned at the bottom of the electron column; it contains the specimen and an array of detectors that collect the emitted signals;
— a system of pumps that maintains the electron gun chamber and electron column under high vacuum to preserve the reliability and stability of the electron source.

VACUUM IN THE SPECIMEN CHAMBER

Conventional SEM is performed with the electron column and specimen chamber maintained at a high vacuum so that conductive specimens can be examined. However, recent developments have enabled the examination of non-conductive specimens and hydrated materials either in a humid or wet atmosphere using environmental SEM (ESEM), or in a dry partial vacuum using variable pressure SEM (VPSEM) at pressures ranging from 10 Pa to 10^3 Pa. A differential vacuum pumping system keeps the gun chamber at a high vacuum relative to the low vacuum (sometimes close to atmospheric pressure) in the specimen chamber. An advantage of using ESEM or VPSEM is that the microscope can also be operated in high vacuum mode.

ELECTRON EMITTERS

There are 2 main types of electron sources:
— *thermionic emission*. A widely-used thermionic source consists of a filament, usually a tungsten wire, heated by passing an electrical current directly through it.
An alternative is a lanthanum hexaboride (LaB_6) emitter, which consists of an indirectly heated single crystal; it has a much greater electron yield and is much brighter than a tungsten emitter.
— *field emission (FE)*. Electrons are emitted from the ultra-sharp tip of a fine-pointed tungsten wire immersed within an intense electrostatic field. Used in high-resolution electron microscopes, FE emitters give an intensely bright, small-diameter and low-current electron beam. They are very stable and have an operating life of many thousands of hours. FE-SEM offers significant advantages, because it produces high-resolution images at low accelerating voltages (down to a few hundreds of volts), with increased signal-to-noise ratios (giving low-noise, high-quality images) and with a superior depth of field.

DETECTORS

A cluster of different detectors (see Figure 2.9.52-2) are positioned at optimised distances close to the specimen and collect the variety of signals emitted during interaction with the electron beam.

Secondary electron detectors

Most high-vacuum electron microscopes are fitted with an Everhart-Thornley (E-T) detector positioned to one side of the specimen. E-T detectors are sensitive to the low-energy secondary electrons that originate from a shallow depth (typically less than 50 nm) below the surface of a specimen.

The E-T detector has a positively biased wire grid in front of it to attract electrons towards a scintillator which converts the secondary electrons into flashes of light that are directed into a photomultiplier. Secondary electrons can follow curved paths from areas on specimens that may not be in the direct line of sight of the detector. As a consequence, secondary electron images tend to have high contrast and show considerable surface details that emphasise topographical features and variations in surface roughness across specimens.

In addition to secondary electrons, E-T detectors are also sensitive to backscattered electrons emitted from areas on the specimen that happen to be in the direct line of sight of the detector. As a consequence, secondary electron images include contributions from both secondary electrons and backscattered electrons and it is this combination that produces the three-dimensional effect that is a distinctive characteristic of secondary electron images.

An E-T detector cannot be used in ESEM or VPSEM because secondary electrons emitted from a specimen are scattered and absorbed by the gas molecules in the chamber. To observe secondary electron images in ESEM or VPSEM, a detector that is sensitive to the small amount of light that is emitted from the ionised gas molecules surrounding the specimen (a process called gas luminescence) in the specimen chamber is used. It is this cloud of positive ions around the specimen that also neutralises any negative charge accumulation.

Backscattered electron detectors

Backscattered electrons have higher energies than secondary electrons and are emitted over a broad angular range. Consequently, the detector is positioned close to and above the specimen. Most high-vacuum and low-vacuum electron microscopes are fitted with a dedicated backscattered electron detector that uses either a scintillator or solid-state diodes.

Scintillator detectors work in the same way as E-T secondary electron detectors by detecting electrons as flashes of light, but have no biased grid to attract electrons towards them. Solid-state backscattered electron detectors consist of an annulus having 4 or 5 separate photodiodes arranged as an array of segments. The diodes can be turned on or off in different combinations to allow topographic imaging, compositional imaging or both together.

The emission of backscattered electrons increases with the average atomic number of the various components (pure or composite) of the specimen. This behaviour can be exploited to examine the spatial distribution and homogeneity of components containing light and heavy atoms in mixtures such as powder blends, compressed tablets and specimens contaminated with foreign matter. Backscattered electron compositional images do not reveal which elements are present in a specimen but they do show where high atomic number materials are relative to low atomic number materials. Materials consisting mainly of heavy atoms (e.g. iron, bromine) appear brighter than those having lighter atoms (e.g. carbon, nitrogen, oxygen, aluminium).
To determine which elements are actually present, elemental X-ray microanalysis is used.

Unlike secondary electron detectors, backscattered electron detectors are not greatly affected by electrical charging at the specimen surface. Therefore, non-conducting specimens can be imaged in high-vacuum mode and in low-vacuum mode using a backscattered electron detector.

Both scintillator and solid-state backscattered electron detectors are also very sensitive to visible light and can therefore also function as cathodoluminescence detectors.

Cathodoluminescence detectors

The weak-intensity light emitted from cathodoluminescent materials is collected by a retractable paraboloidal mirror and directed into a light-sensitive scintillator detector (not shown in Figure 2.9.52-2). The mirror is inserted just above the specimen and is retracted when not in use. The electron beam passes through a small hole in the mirror so that it strikes the specimen to induce the emission of visible light.

In its simplest form, the detector does not discriminate between different wavelengths of light and greyscale images are produced with cathodoluminescent areas on a specimen

being shown as bright. More complex detectors have the capability to select different wavelengths of light being emitted to produce monochromatic images tuned to a single wavelength that represents a specific material.
Cathodoluminescence spectral analysis is achieved by passing polychromatic light emitted from the specimen into a spectrometer where it is dispersed to produce a visible light spectrum.

Spectral analysis of the emitted light is not widely used but has applications in the examination and characterisation of some organic and inorganic materials. It can be used to acquire diagnostic information about the chemistry and structure of single materials and spectral imaging can be used for analysing mixtures of materials.

Elemental X-ray microanalysis detectors
An X-ray analyser fitted to the specimen chamber of an electron microscope enables the rapid and non-destructive elemental analysis of materials being examined. 2 main detector types are available and these detect either the dispersed energies (energy-dispersive X-ray microanalysis, EDX) or the dispersed wavelengths (wavelength-dispersive X-ray microanalysis, WDX) of the characteristic X-rays emitted from specimens (for more details, see general chapter *2.2.37*).

PROCEDURE

SPECIMEN PREPARATION / PRESENTATION

Prior to preparing a specimen for examination by SEM, the purpose of the examination must be considered because this can affect the way the sample is treated.

In addition, the electrical conductivity of the specimen must be considered to minimise charge accumulation as the electron beam scans across the specimen. Numerous methods have been developed to prepare specimens to maintain integrity whilst minimising artefacts.
The preparation of most pharmaceutical samples is simple and quick and does not require specialised equipment or complex processes.

Specimen holders, called stubs, are used to support powders, single particles, tablets, freeze-dried cakes, capsules and beads. Rapid-curing, vacuum compatible glue or electrically conductive silver or carbon paints are ideal for holding large objects that are up to a few millimetres in diameter. Fine powders and small objects can be attached to stubs on double-sided adhesive tape or on sticky tabs. Large samples may have to be reduced in size to fit onto a stub or into the specimen chamber and tablets can be broken open to expose their cores before being attached securely to a stub.

Powders can be simply sprinkled or poured onto a stub that has had a thin layer of adhesive applied to it and excess loose powder is then tapped off or blown off with a gentle stream of inert compressed gas. A rapid and simple method for powders is to attach double-sided adhesive tape onto a stub and dip it gently into the powder so that a thin layer sticks to the tape, and excess powder is then blown off (taking care not to inhale the airborne powder).

When preparing powder samples, cross-contamination must be avoided because the presence in the specimen of just a single particle from another material can lead to an incorrect interpretation of an image or chemical analysis. For this reason, it is not good practice to disperse powder particles onto a specimen stub using a brush, because the brush must be decontaminated or discarded after a single use.
For microanalysis, the use of inert/plastic tools (needles, spatulas, tweezers, etc.) is preferred for sample manipulation since contaminant particles could potentially be released from metal tools.

SPECIMEN COATING

Most pharmaceutical materials are readily examined without the need for prolonged and complicated preparation techniques. However, such materials tend to be electrically non-conductive and so specimens that are examined using high-vacuum SEM need to be coated with an ultra-thin layer of conductive material. Without a conductive coating, specimens will acquire a net negative charge as the electron beam scans across them; this causes the specimen to glow brightly and, when it discharges, disturbing flashes and bright streaks will be seen in the image. Suitable conductive materials for coating include metals, such as platinum and gold, and these can be applied to rough and smooth specimen surfaces using a plasma sputter coater. If carbon is to be used, it needs to be evaporated in a very high vacuum because it cannot be sputtered. In addition to reducing charging effects, a conductive coating will increase the emission of secondary electrons to give brighter images and will also transfer localised electron beam-induced heat away from the specimen. Some powders consisting of very small particles (such as colloidal silica) may need to be sputter coated 3 or 4 times to prevent charging because the coating material initially fails to form a continuous conductive layer.

Some beam-sensitive specimens, such as semi-solids or wet materials, may have to be cooled or frozen using a cooling stage to minimise degradation or evaporation. With respect to this, FE-SEM allows the surfaces of labile specimens to be examined with an electron beam that has a very low energy (e.g. 500 volts or less), and this can help to minimise or even eliminate beam-induced degradation.

Specimens to be analysed by elemental X-ray microanalysis are typically not coated with metal because the coat would add extra peaks to the X-ray spectrum and this could interfere with the analysis or even obscure minor amounts of some elements, thereby precluding the possibility of quantitative determinations of unknowns. Most elemental analysers are capable of detecting light elements, so even a thin carbon coat could hinder the interpretation of the spectrum. To minimise or exclude potential problems and artefacts associated with specimen coating, non-conductive materials can be examined uncoated using ESEM or VPSEM. Software correction for any coating may need to be applied.

OPERATION

The electron microscope is operated with a beam-accelerating voltage that is appropriate to produce images that reveal the information of interest about a specimen. For example, a low voltage (e.g. less than 5 kV) can be used to image surface details and a higher voltage (e.g. greater than 10 kV) increases the resolving power and can be used for the analysis of a wide range of elements. The most useful accelerating voltage range is about 2 kV to 20 kV because most elements of interest can be ionized by electrons with energies in this range.

Adjustment of the objective lens focuses the beam on the specimen over a wide range of working distances to accommodate large and small specimens. The depth of field can also be increased by selecting smaller beam apertures to enable the full depth of thick specimens to be in acceptable focus simultaneously.

When SEM is used to examine specimens in a high vacuum, very high magnifications in excess of 10 000 × can be achieved to resolve fine detail down to about 3 nm,

depending upon the specimen. This is possible because the electron beam can be focused without being scattered by gas molecules. For ESEM or VPSEM, a consequence of gas or water vapour being present in the specimen chamber is that the electron beam suffers some lateral scattering (called skirting). This scattering can inhibit high-resolution imaging because the beam cannot be focused as finely as it would be in a high vacuum. By selecting a shorter working distance and optimising the gas pressure, this adverse effect can be minimised.

Lateral spatial resolutions of 1 nm or better become possible (depending upon the specimen being examined) when using FE-SEM. To achieve this high resolving power, a beam-accelerating voltage in excess of about 15 kV may be required, but a high beam voltage could damage beam-sensitive materials. For most organic solids, the electron beam will penetrate many micrometres into the specimen and surface detail will be lost due to the scattering and absorption of the emitted electrons. In order to reveal the surface details of specimens, the electron microscope must be operated at a much lower voltage, and this is at the expense of resolution. Most pharmaceutical specimens studied by SEM are likely to be examined at a magnification less than 10 000 × and so a high resolving power is typically not needed.

COMBINATION OF SEM AND X-RAY MICROANALYSIS

This combination enables the identification of the elemental compositions of specimens and elemental mapping to visualise the distributions of elements, for example in tablets and blends.

Element maps are easily and quickly generated to visualise the spatial distribution of the elements present in a specimen at low and high magnifications. Cross-sections cut or fractured through tablet cores and powders that have been lightly pressed flat can be mapped to reveal the relationships between their components. This technique is useful to compare the differences between samples to indicate why some perform better than others. It is important to have surfaces that are not rough because emitted X-rays follow straight paths and so may not be detected in areas (effectively in shadows) that are not in direct line of sight of the X-ray detector. This artefact can be reduced by tilting the specimen towards the detector.

X-ray microanalysis is also used for the investigation of particulate matter. Black spots in tablets, for example, are often caused by particles of metal or rubber debris, caused by the wearing of tablet presses, that have subsequently been incorporated into the tablet as a visible defect. SEM-EDX is an ideal technique to identify them because it is non-destructive and can often be used to distinguish between different metals so that the source and root cause can be identified. Also, particles in vials and syringes of solutions for injection can be examined and analysed after they have been isolated by filtration or removed using a micropipette.

EQUIPMENT PERFORMANCE

SEM user requirements, in addition to manufacturer's recommendations, provide a basis for the system performance evaluation. For size measurements, accuracy of the displayed scale bar represents a critical parameter that should be checked at both low and high magnifications using certified calibration test specimens (available from SEM accessory suppliers). As accuracy of scale can be influenced by instrumental parameters, such as accelerating voltage and working distance, or by the specimen itself, it should be checked under different operating conditions to allow for instrument variations using, for example, a bracketing concept. Accuracy of scale should be checked in orthogonal directions and the typical accuracy of the displayed scale should be 10 per cent or better. If justified, other acceptance criteria, such as image resolution, might be applied.

For elemental analysis by EDX, the accuracy and reproducibility of the energy scale over a specific energy range (e.g. 0-5 keV or 0-20 keV) represents a parameter that should be checked and calibrated according to the manufacturer's instrument operating instructions using suitable reference materials (see general chapter *2.2.37*). These single element materials are used because they have multiple X-ray emission peaks at well-defined energies and intensities across the spectral range being calibrated.
The intensities of the emitted X-rays can be influenced by other instrumental parameters, such as accelerating voltage or the working distance, and should be checked for relevant instrumental parameters using, for example, a bracketing concept. If justified, other acceptance criteria (such as detector resolution) might be used.

P. Particle Size Analysis by Laser Light Diffraction[1]

(Ph. Eur. method 2.9.31)

The method is based on the ISO standards 13320-1(1999) and 9276-1(1998).

INTRODUCTION

The laser light diffraction technique used for the determination of particle-size distribution is based on the analysis of the diffraction pattern produced when particles are exposed to a beam of monochromatic light. Historically, the early laser diffraction instruments only used scattering at small angles. However, the technique has since been broadened to include laser light scattering in a wider angular range and application of the Mie theory, in addition to the Fraunhofer approximation and anomalous diffraction.

The technique cannot distinguish between scattering by single particles and scattering by clusters of primary particles, i.e. by agglomerates or aggregates. As most particulate samples contain agglomerates or aggregates and as the focus of interest is generally on the size distribution of primary particles, the clusters are usually dispersed into primary particles before measurement.

For non-spherical particles, an equivalent sphere-size distribution is obtained because the technique assumes spherical particles in its optical model. The resulting particle-size distribution may differ from those obtained by methods based on other physical principles (e.g. sedimentation, sieving).

This chapter provides guidance for the measurement of size distributions of particles in different dispersed systems, for example, powders, sprays, aerosols, suspensions, emulsions, and gas bubbles in liquids, through analysis of their angular light-scattering patterns. It does not address specific requirements of particle size measurement of specific products.

PRINCIPLE

A representative sample, dispersed at an adequate concentration in a suitable liquid or gas, is passed through a beam of monochromatic light, usually a laser. The light scattered by the particles at various angles is measured by a multi-element detector. Numerical values representing the scattering pattern are then recorded for subsequent analysis. These scattering pattern values are then transformed, using an appropriate optical model and mathematical procedure, to yield the proportion of total volume to a discrete number of size classes, forming a volumetric particle-size distribution.

INSTRUMENT

The instrument is located in an environment where it is not affected by electrical noise, mechanical vibrations, temperature fluctuations, humidity or direct bright light.

An example of a set-up of a laser light diffraction instrument is given in Figure 2.9.31.-1. Other equipment may be used.

The instrument comprises a laser light source, beam processing optics, a sample measurement region (or cell), a Fourier lens, and a multi-element detector for measuring the scattered light pattern. A data system is also required for deconvolution of the scattering data into a volumetric size distribution and associated data analysis and reporting.

The particles can enter the laser beam in 2 positions. In the conventional case the particles enter the parallel beam before the collecting lens and within its working distance.
In so-called reversed Fourier optics the particles enter behind the collecting lens and thus, in a converging beam.
The advantage of the conventional set-up is that a reasonable path length for the sample is allowed within the working distance of the lens. The second set-up allows only small path lengths but enables measurement of scattered light at larger angles, which is useful when submicron particles are present.

The interaction of the incident light beam and the ensemble of dispersed particles results in a scattering pattern with different light intensities at various angles. The total angular intensity distribution, consisting of both direct and scattered light, is then focused onto a multi-element detector by a lens or a series of lenses. These lenses create a scattering pattern that, within limits, does not depend on the location of the particles in the light beam. Hence, the continuous angular intensity distribution is converted into a discrete spatial intensity distribution on a set of detector elements.

It is assumed that the measured scattering pattern of the particle ensemble is identical to the sum of the patterns from all individual single scattering particles presented in random relative positions. Note that only a limited angular range of scattered light is collected by the lens(es) and, therefore, by the detector.

DEVELOPMENT OF THE METHOD

The measurement of particle size by laser diffraction can give reproducible data, even in the sub-micron region, provided the instrument used and the sample tested are carefully controlled to limit variability of the test conditions (e.g. dispersion medium, method of preparation of the sample dispersion).

Traditionally, the measurement of particle size using laser diffraction has been limited to particles in the range of approximately 0.1 µm to 3 mm. Because of recent advances in lens and equipment design, newer instruments are capable of exceeding this range routinely. With the validation report the user demonstrates the applicability of the method for its intended use.

Sampling

The sampling technique must be adequate to obtain a representative sample of a suitable volume for the particle-size measurement. Sample splitting techniques such as rotating riffler or the cone and quartering method may be applied.

Evaluation of the dispersion procedure

Inspect the sample to be analysed, visually or with the aid of a microscope, to estimate its size range and particle shape. The dispersion procedure must be adjusted to the purpose of the measurement. The purpose may be such that it is preferable to deagglomerate clusters into primary particles as far as possible, or it may be desirable to retain clusters as intact as possible. In this sense, the particles of interest may be either primary particles or clusters.

For the development of a method it is highly advisable to check that comminution of the particles does not occur, and conversely, that dispersion of particles or clusters is satisfactory. This can usually be done by changing the dispersing energy and monitoring the change of the particle-size distribution. The measured size distribution must not change significantly when the sample is well dispersed and the particles are neither fragile nor soluble. Moreover, if the manufacturing process (e.g. crystallisation, milling) of the

material has changed, the applicability of the method must be verified (e.g. by microscopic comparison).

Sprays, aerosols and gas bubbles in a liquid should be measured directly, provided that their concentration is adequate, because sampling or dilution generally alters the particle-size distribution.

In other cases (such as emulsions, pastes and powders), representative samples may be dispersed in suitable liquids. Dispersing aids (wetting agents, stabilisers) and/or mechanical forces (e.g. agitation, sonication) are often applied for deagglomeration or deaggregation of clusters and stabilisation of the dispersion. For these liquid dispersions, a recirculating system is most commonly used, consisting of an optical measuring cell, a dispersion bath usually equipped with stirrer and ultrasonic elements, a pump, and tubing. Non-recirculating, stirred cells are useful when only small amounts of a sample are available or when special dispersion liquids are used.

Dry powders can also be converted into aerosols through the use of suitable dry powder dispersers, which apply mechanical force for deagglomeration or deaggregation. Generally, the dispersers use the energy of compressed gas or the differential pressure of a vacuum to disperse the particles to an aerosol, which is blown through the measuring zone, usually into the inlet of a vacuum unit that collects the particles. However, for free flowing, coarser particles or granules the effect of gravity may be sufficient to disperse the particles adequately.

If the maximum particle size of the sample exceeds the measuring range of the instrument, the material that is too coarse can be removed by sieving and the mass and percentage of removed material are reported. However, after pre-sieving, note that the sample is no longer representative, unless otherwise proven.

Optimisation of the liquid dispersion

Liquids, surfactants, and dispersing aids used to disperse powders must:

- be transparent at the laser wavelength and practically free from air bubbles or particles;
- have a refractive index that differs from that of the test material;
- be non-solvent of the test material (pure liquid or pre-filtered, saturated solution);
- not alter the size of the test materials (e.g. by solubility, solubility enhancement, or recrystallisation effects);
- favour easy formation and stability of the dispersion;
- be compatible with the materials used in the instrument (such as O-rings, gaskets, tubing, etc.);
- possess a suitable viscosity to facilitate recirculation, stirring and filtration.

Surfactants and/or dispersing aids are often used to wet the particles and to stabilise the dispersion. For weak acids and weak bases, buffering of the dispersing medium at low or high pH respectively can assist in identifying a suitable dispersant.

A preliminary check of the dispersion quality can be performed by visual or microscopic inspection. It is also possible to take fractional samples out of a well-mixed stock dispersion. Such stock dispersions are formed by adding a liquid to the sample while mixing it with, for example, a glass rod, a spatula or a vortex mixer. Care must be taken to ensure the transfer of a representative sample and that settling of larger particles does not occur. Therefore a sample paste is prepared or sampling is carried out quickly from a suspension maintained under agitation.

Optimisation of the gas dispersion

For sprays and dry powder dispersions, a compressed gas free from oil, water and particles may be used. To remove such materials from the compressed gas, a dryer with a filter can be used. Any vacuum unit should be located away from the measurement zone, so that its output does not disturb the measurement.

Determination of the concentration range

In order to produce an acceptable signal-to-noise ratio in the detector, the particle concentration in the dispersion must exceed a minimum level. Likewise, it must be below a maximum level in order to avoid multiple scattering. The concentration range is influenced by the width of the laser beam, the path length of the measurement zone, the optical properties of the particles, and the sensitivity of the detector elements.

In view of the above, measurements must be performed at different particle concentrations to determine the appropriate concentration range for any typical sample of material. (Note: in different instruments, particle concentrations are usually represented by differently scaled and differently named numbers, e.g. obscuration, optical concentration, proportional number of total mass).

Determination of the measuring time

The time of measurement, the reading time of the detector and the acquisition frequency are determined experimentally in accordance with the required precision. Generally, the time for measurement permits a large number of detector scans or sweeps at short time intervals.

Selection of an appropriate optical model

Most instruments use either the Fraunhofer or the Mie theory, though other approximation theories are sometimes applied for calculation of the scattering matrix. The choice of the theoretical model depends on the intended application and the different assumptions (size, absorbance, refractive index, roughness, crystal orientation, mixture, etc.) made for the test material. If the refractive index values (real and imaginary parts for the used wavelength) are not exactly known, then the Fraunhofer approximation or the Mie theory with a realistic estimate of the refractive index can be used. The former has the advantages that it is simple and it does not need refractive index values; the latter usually provides less-biased particle-size distributions for small particles. For instance, if the Fraunhofer model is used for samples containing an appreciable amount of small, transparent particles, a significantly larger amount of small particles may be calculated. In order to obtain traceable results, it is essential to document the refractive index values used, since small differences in the values assumed for the real and imaginary part of the complex refractive index may cause significant differences in the resulting particle-size distributions. Small values of the imaginary part of the refractive index (about 0.01-0.1 i) are often applied to allow the correction of the absorbance for the surface roughness of the particles. It should be noted, in general, that the optical properties of the substance to be tested, as well as the structure (e.g. shape, surface roughness and porosity), bear upon the final result.

Validation

Typically, the validity of a procedure may be assessed by the evaluation of its specificity, linearity, range, accuracy, precision and robustness. In particle-size analysis by laser light diffraction, specificity as defined by ICH is not applicable as it is not possible to discriminate between different components in a sample, nor is it possible to

discriminate agglomerates from dispersed particles unless properly complemented by microscopic techniques. Exploring a linear relationship between concentration and response, or a mathematical model for interpolation, is not applicable to this procedure. Rather than evaluating linearity, this method requires the definition of a concentration range within which the result of the measurements does not vary significantly. Concentrations below that range produce an error due to a poor signal-to-noise ratio, while concentrations above that range produce an error due to multiple scattering. The range depends mostly on the instrument hardware. Accuracy should be confirmed through an appropriate instrument qualification and comparison with microscopy, while precision may be assessed by means of a repeatability determination.

The attainable repeatability of the method mainly depends on the characteristics of the material (milled/not milled, robust/fragile, width of its size distribution, etc.), whereas the required repeatability depends on the purpose of the measurement. Mandatory limits cannot be specified in this chapter, as repeatabilities (different sample preparations) may vary appreciably from one substance to another. However, it is good practice to aim at acceptance criteria for repeatability such as $s_{rel} \leq 10$ per cent [$n = 6$] for any central value of the distribution (e.g. for x_{50}). Values at the sides of the distribution (e.g. x_{10} and x_{90}) are oriented towards less stringent acceptance criteria such as $s_{rel} \leq 15$ per cent [$n = 6$]. Below 10 µm, these values must be doubled. Robustness may be tested during the selection and optimisation of the dispersion media and forces. The change of the dispersing energy may be monitored by the change in the particle-size distribution.

MEASUREMENT

Precautions

The instructions given in the instrument manual are followed:

- never look into the direct path of the laser beam or its reflections;
- earth all instrument components to prevent ignition of solvents or dust explosions;
- check the instrument set-up (e.g. warm-up, required measuring range and lens, appropriate working distance, position of the detector, no direct bright daylight);
- in the case of wet dispersions, avoid air bubbles, evaporation of liquid, schlieren or other inhomogeneities in the dispersion; similarly, avoid improper mass-flow from the disperser or turbulent air-flow in the case of dry dispersions; such effects can cause erroneous particle-size distributions.

Measurement of the light scattering of dispersed sample(s)

After proper alignment of the optical part of the instrument, a blank measurement of the particle-free dispersion medium must be performed using the same method as that used for the measurement of the sample. The background signal must be below an appropriate threshold. The detector data are saved in order to substract them later from the data obtained with the sample. The sample dispersion is measured according to the developed method.

For each detector element, an average signal is calculated, sometimes together with its standard deviation.
The magnitude of the signal from each detector element depends upon the detection area, the light intensity and the quantum efficiency. The co-ordinates (size and position) of the detector elements together with the focal distance of the lens determine the range of scattering angles for each element. Most instruments also measure the intensity of the central (unscattered) laser beam. The ratio of the intensity of a dispersed sample to that in its absence (a blank measurement) indicates the proportion of scattered light and hence the particle concentration.

Conversion of scattering pattern into particle-size distribution

This deconvolution step is the inverse of the calculation of a scattering pattern for a given particle-size distribution. The assumption of spherical particle shape is particularly important as most algorithms use the mathematical solution for scattering from spherical particles. Furthermore, the measured data always contain some random and systematic errors, which may vitiate the size distributions. Several mathematical procedures have been developed for use in the available instruments. They contain some weighting of deviations between measured and calculated scattering patterns (e.g. least squares), some constraints (e.g. non-negativity for amounts of particles), and/or some smoothing of the size distribution curve.

The algorithms used are specific to each make and model of equipment, and are proprietary. The differences in the algorithms between different instruments may give rise to differences in the calculated particle-size distributions.

Replicates

The number of replicate measurements (with individual sample preparations) to be performed depends on the required measurement precision. It is recommended to set this number in a substance-specific method.

REPORTING OF RESULTS

The particle-size distribution data are usually reported as cumulative undersize distribution and/or as density distribution by volume. The symbol x is used to denote the particle size, which in turn is defined as the diameter of a volume-equivalent sphere. $Q3(x)$ denotes the volume fraction undersize at the particle size x. In a graphical representation, x is plotted on the abscissa and the dependent variable Q3 on the ordinate. Most common characteristic values are calculated from the particle-size distribution by interpolation. The particle sizes at the undersize values of 10 per cent, 50 per cent, and 90 per cent (denoted as x_{10}, x_{50}, and x_{90} respectively) are frequently used. x_{50} is also known as the median particle size. It is recognised that the symbol d is also widely used to designate the particle size, thus the symbol x may be replaced by d.

Moreover, sufficient information must be documented about the sample, the sample preparation, the dispersion conditions, and the cell type. As the results depend on the particular instrument, data analysis program, and optical model used, these details must also be documented.

CONTROL OF THE INSTRUMENT PERFORMANCE

Use the instrument according to the manufacturer's instructions and carry out the prescribed qualifications at an appropriate frequency, according to the use of the instrument and substances to be tested.

Calibration

Laser diffraction systems, although assuming idealised properties of the particles, are based on first principles of laser light scattering. Thus, calibration in the strict sense is not required. However, it is still necessary to confirm that the instrument is operating correctly. This can be undertaken using any certified reference material that is acceptable in industrial practice. The entire measurement procedure is

examined, including sample collection, sample dispersion, sample transport through the measuring zone, measurement, and the deconvolution procedure. It is essential that the total operational procedure is fully described.

The preferred certified reference materials consist of spherical particles of a known distribution. They must be certified as to the mass-percentage size distribution by an absolute technique, if available, and used in conjunction with an agreed, detailed operation procedure. It is essential that the real and imaginary parts of the complex refractive index of the material are indicated if the Mie theory is applied in data analysis. The representation of the particle-size distribution by volume will equal that of the distribution by mass, provided that the density of the particles is the same for all size fractions.

The response of a laser diffraction instrument is considered to meet the requirements if the mean value of x_{50} from at least 3 independent measurements does not deviate by more than 3 per cent from the certified range of values of the certified reference material. The mean values for x_{10} and x_{90} must not deviate by more than 5 per cent from the certified range of values. Below 10 µm, these values must be doubled.

Although the use of materials consisting of spherical particles is preferable, non-spherical particles may also be employed. Preferably, these particles have certified or typical values from laser diffraction analyses performed according to an agreed, detailed operating procedure. The use of reference values from methods other than laser diffraction may cause a significant bias. The reason for this bias is that the different principles inherent in the various methods may lead to different sphere-equivalent diameters for the same non-spherical particle.

Although the use of certified reference materials is preferred, other well-defined reference materials may also be employed. They consist of substances of typical composition and particle-size distribution for a specified class of substances. Their particle-size distribution has proven to be stable over time. The results must comply with previously determined data, with the same precision and bias as for the certified reference material.

Qualification of the system

In addition to the calibration, the performance of the instrument must be qualified at regular time intervals or as frequently as appropriate. This can be undertaken using any suitable reference material as mentioned in the previous paragraph.

The qualification of the system is based on the concept that the equipment, electronics, software and analytical operations constitute an integral system, which can be evaluated as an entity. Thus the entire measurement procedure is examined, including sample collection, sample dispersion, sample transport through the measuring zone, and the measurement and deconvolution procedure. It is essential that the total operational procedure is fully described.

In general, unless otherwise specified in the individual monograph, the response of a laser diffraction instrument is considered to meet the requirements if the x_{50} value does not deviate by more than 10 per cent from the range of values of the reference material. If optionally the values at the sides of the distribution are evaluated (e.g. x_{10} and x_{90}), then these values must not deviate by more than 15 per cent from the certified range of values. Below 10 µm, these values must be doubled.

NOTE: for calibration of the instrument, stricter requirements are laid down in the paragraph Calibration.

Q. Characterisation of Crystalline and Partially Crystalline Solids by X-ray Powder Diffraction (XRPD)[1]

(Ph. Eur. method 2.9.33)

Every crystalline phase of a given substance produces a characteristic X-ray diffraction pattern.

Diffraction patterns can be obtained from a randomly oriented crystalline powder composed of crystallites or crystal fragments of finite size. Essentially 3 types of information can be derived from a powder diffraction pattern: angular position of diffraction lines (depending on geometry and size of the unit cell); intensities of diffraction lines (depending mainly on atom type and arrangement, and particle orientation within the sample); and diffraction line profiles (depending on instrumental resolution, crystallite size, strain and specimen thickness).

Experiments giving angular positions and intensities of lines can be used for applications such as qualitative phase analysis (for example, identification of crystalline phases) and quantitative phase analysis of crystalline materials.
An estimate of the amorphous and crystalline fractions[2] can also be made.

The X-ray powder diffraction (XRPD) method provides an advantage over other means of analysis in that it is usually non-destructive in nature (specimen preparation is usually limited to grinding to ensure a randomly oriented sample). XRPD investigations can also be carried out under *in situ* conditions on specimens exposed to non-ambient conditions, such as low or high temperature and humidity.

PRINCIPLE

X-ray diffraction results from the interaction between X-rays and electron clouds of atoms. Depending on the atomic arrangement, interferences arise from the scattered X-rays. These interferences are constructive when the path difference between 2 diffracted X-ray waves differs by an integral number of wavelengths. This selective condition is described by the Bragg equation, also called Bragg's law (see Figure 2.9.33.-1):

$$2d_{hkl}\sin\theta_{hkl} = n\lambda$$

The wavelength λ of the X-rays is of the same order of magnitude as the distance between successive crystal lattice planes, or d_{hkl} (also called 'd-spacings'). θ_{hkl} is the angle between the incident ray and the family of lattice planes, and $\sin\theta_{hkl}$ is inversely proportional to the distance between successive crystal planes or d-spacings.

The direction and spacing of the planes with reference to the unit cell axes are defined by the Miller indices $\{hkl\}$. These indices are the reciprocals, reduced to the next-lower integer, of the intercepts that a plane makes with the unit cell axes. The unit cell dimensions are given by the spacings a, b and c and the angles between them, α, β, and γ.

The interplanar spacing for a specified set of parallel *hkl* planes is denoted by d_{hkl}. Each such family of planes may

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8. Pharmacopoeial harmonisation.*

[2] *There are many other applications of the X-ray powder diffraction technique that can be applied to crystalline pharmaceutical substances such as: determination of crystal structures, refinement of crystal structures, determination of crystallographic purity of crystalline phases, characterisation of crystallographic texture, etc. These applications are not described in this chapter.*

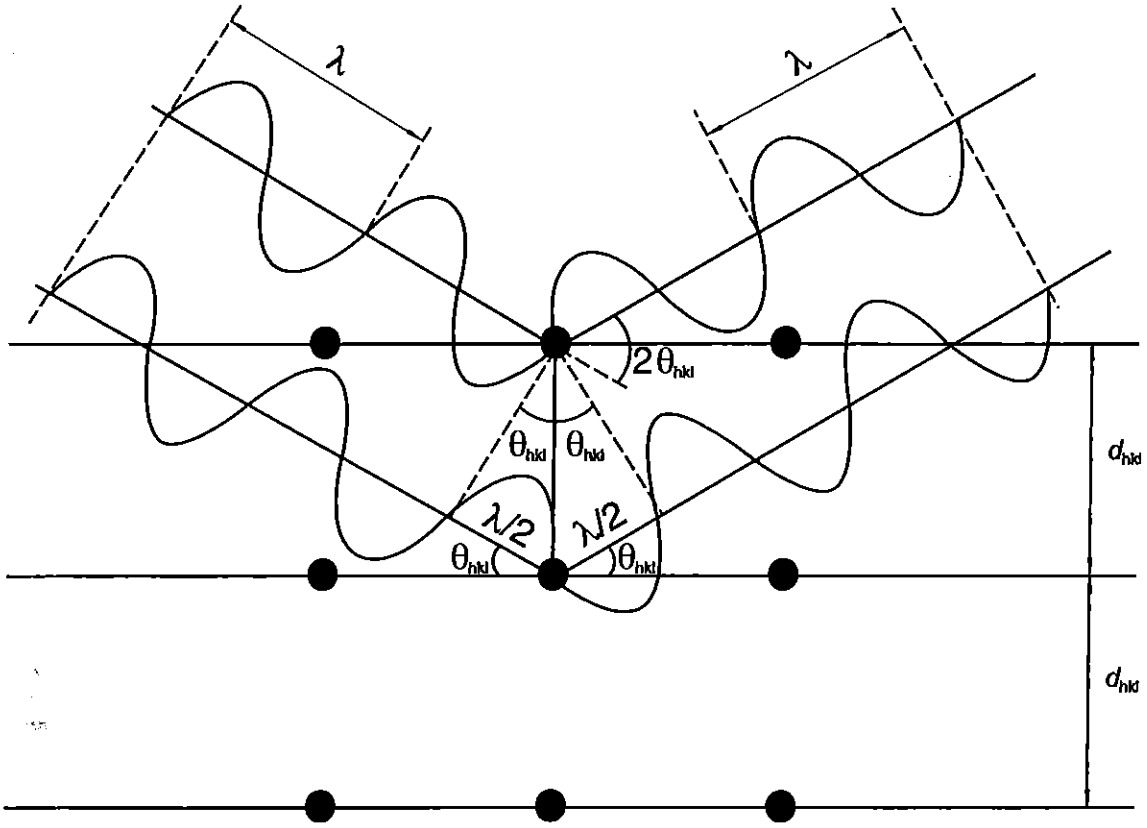

Figure 2.9.33.-1. – *Diffraction of X-rays by a crystal according to Bragg's law*

show higher orders of diffraction where the *d* values for the related families of planes n*h*, n*k*, n*l* are diminished by the factor 1/n (n being an integer: 2, 3, 4, etc.).

Every set of planes throughout a crystal has a corresponding Bragg diffraction angle, θ_{hkl}, associated with it (for a specific wavelength λ).

A powder specimen is assumed to be polycrystalline so that at any angle θ_{hkl} there are always crystallites in an orientation allowing diffraction according to Bragg's law[3]. For a given X-ray wavelength, the positions of the diffraction peaks (also referred to as 'lines', 'reflections' or 'Bragg reflections') are characteristic of the crystal lattice (d-spacings), their theoretical intensities depend on the crystallographic unit cell content (nature and positions of atoms), and the line profiles on the perfection and extent of the crystal lattice. Under these conditions the diffraction peak has a finite intensity arising from atomic arrangement, type of atoms, thermal motion and structural imperfections, as well as from instrument characteristics.

The intensity is dependent upon many factors such as structure factor, temperature factor, crystallinity, polarisation factor, multiplicity and Lorentz factor.

The main characteristics of diffraction line profiles are 2θ position, peak height, peak area and shape (characterised by, for example, peak width or asymmetry, analytical function, empirical representation). An example of the type of powder patterns obtained for 5 different solid phases of a substance are shown in Figure 2.9.33.-2.

[3] *An 'ideal' powder for diffraction experiments consists of a large number of small, randomly oriented spherical crystallites (coherently diffracting crystalline domains). If this number is sufficiently large, there are always enough crystallites in any diffracting orientation to give reproducible diffraction patterns.*

In addition to the diffraction peaks, an X-ray diffraction experiment also generates a more-or-less uniform background, upon which the peaks are superimposed. Besides specimen preparation, other factors contribute to the background, for instance the sample holder, diffuse scattering from air and equipment, other instrumental parameters such as detector noise, general radiation from the X-ray tube, etc. The peak-to-background ratio can be increased by minimising background and by choosing prolonged exposure times.

INSTRUMENT

Instrument set-up

X-ray diffraction experiments are usually performed using powder diffractometers or powder cameras.

A powder diffractometer generally comprises 5 main parts: an X-ray source; incident beam optics, which may perform monochromatisation, filtering, collimation and/or focusing of the beam; a goniometer; diffraction beam optics, which may perform monochromatisation, filtering, collimation and focusing or parallelising of the beam; and a detector. Data-collection and data-processing systems are also required and are generally included in current diffraction measurement equipment.

Depending on the type of analysis to be performed (phase identification, quantitative analysis, lattice parameters determination, etc.), different XRPD instrument configurations and performance levels are required.

The simplest instruments used to measure XRPD patterns are powder cameras. The replacement of photographic film as the detection method by photon detectors has led to the design of diffractometers in which the geometric arrangement of the optics is not truly focusing but parafocusing, such as in the Bragg-Brentano geometry. The Bragg-Brentano parafocusing configuration is currently the most widely used and is therefore briefly described here.

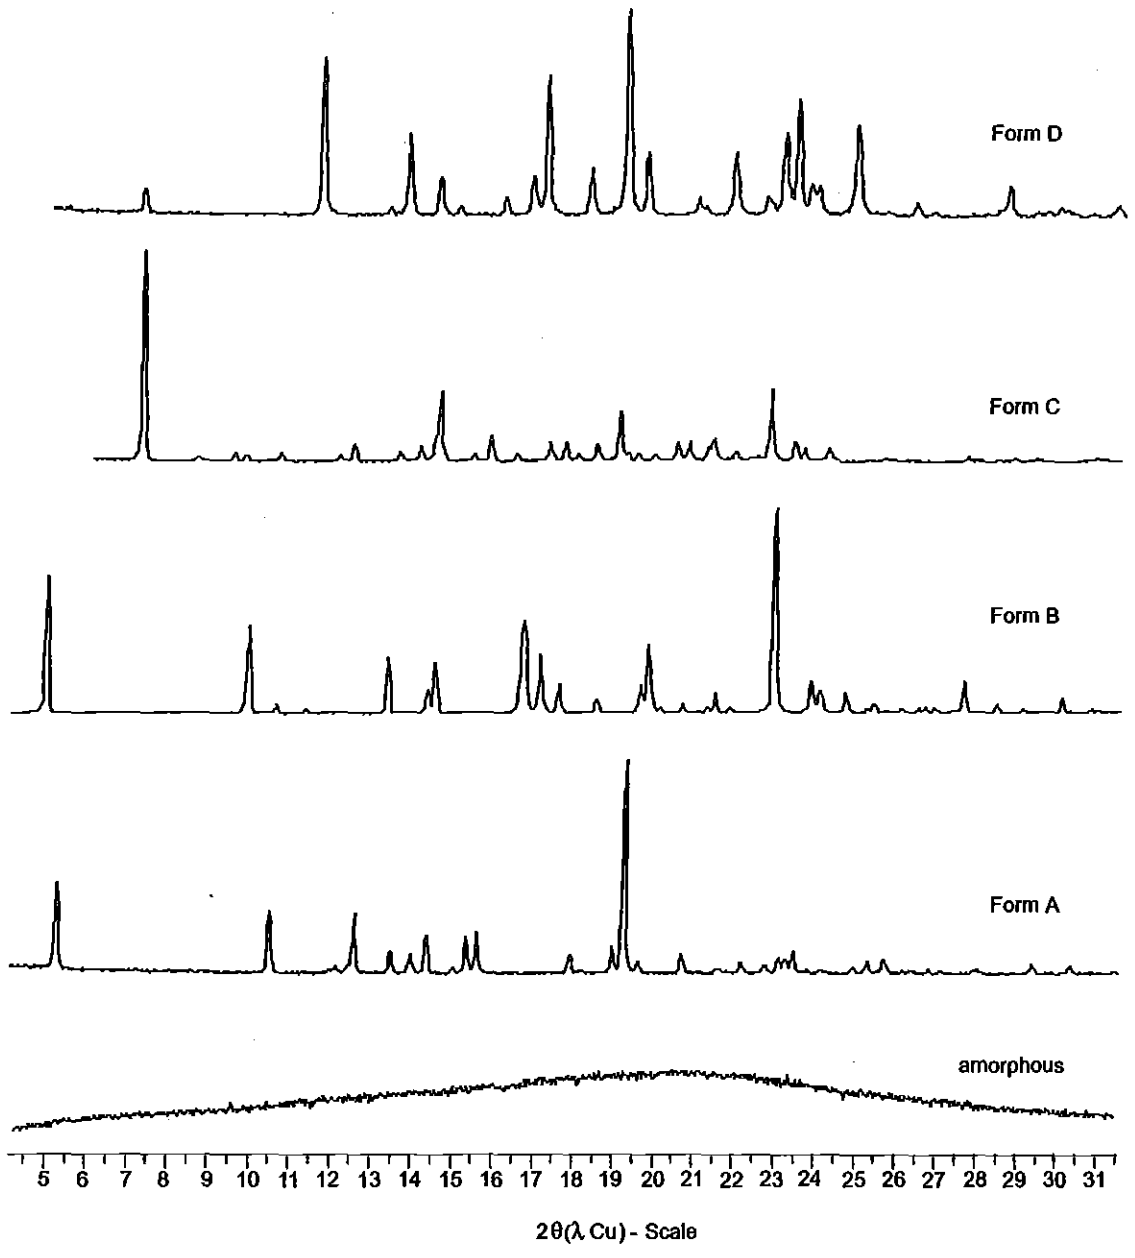

Figure 2.9.33.-2. – *X-ray powder diffraction patterns collected for 5 different solid phases of a substance (the intensities are normalised)*

A given instrument may provide a horizontal or vertical θ/2θ geometry or a vertical θ/θ geometry. For both geometries, the incident X-ray beam forms an angle θ with the specimen surface plane and the diffracted X-ray beam forms an angle 2θ with the direction of the incident X-ray beam (an angle θ with the specimen surface plane).
The basic geometric arrangement is represented in Figure 2.9.33.-3. The divergent beam of radiation from the X-ray tube (the so-called 'primary beam') passes through the parallel plate collimators and a divergence slit assembly and illuminates the flat surface of the specimen. All the rays diffracted by suitably oriented crystallites in the specimen at an angle 2θ converge to a line at the receiving slit. A second set of parallel plate collimators and a scatter slit may be placed either behind or before the receiving slit. The axes of the line focus and of the receiving slit are at equal distances from the axis of the goniometer. The X-ray quanta are counted by a radiation detector, usually a scintillation counter, a sealed-gas proportional counter, or a position-sensitive solid-state detector such as imaging plate or CCD detector. The receiving slit assembly and the detector are coupled together and move tangentially to the focusing circle. For θ/2θ scans the goniometer rotates the specimen about the same axis as that of the detector, but at half the rotational speed, in a θ/2θ motion. The surface of the specimen thus remains tangential to the focusing circle. The parallel plate collimator limits the axial divergence of the beam and hence partially controls the shape of the diffracted line profile.

A diffractometer may also be used in transmission mode. The advantage with this technology is to lessen the effects due to preferred orientation. A capillary of about 0.5-2 mm thickness can also be used for small sample amounts.

X-ray radiation

In the laboratory, X-rays are obtained by bombarding a metal anode with electrons emitted by the thermionic effect and accelerated in a strong electric field (using a high-voltage

generator). Most of the kinetic energy of the electrons is converted to heat, which limits the power of the tubes and requires efficient anode cooling. A 20- to 30-fold increase in brilliance can be obtained using rotating anodes and by using X-ray optics. Alternatively, X-ray photons may be produced in a large-scale facility (synchrotron).

The spectrum emitted by an X-ray tube operating at sufficient voltage consists of a continuous background of polychromatic radiation and additional characteristic radiation that depends on the type of anode. Only this characteristic radiation is used in X-ray diffraction experiments. The principal radiation sources utilised for X-ray diffraction are vacuum tubes utilising copper, molybdenum, iron, cobalt or chromium as anodes; copper, molybdenum or cobalt X-rays are employed most commonly for organic substances (the use of cobalt anodes can be especially preferred to separate distinct X-ray lines).

The choice of radiation to be used depends on the absorption characteristics of the specimen and possible fluorescence by atoms present in the specimen.

The wavelengths used in powder diffraction generally correspond to the K_α radiation from the anode. Consequently, it is advantageous to make the X-ray beam 'monochromatic' by eliminating all the other components of the emission spectrum. This can be partly obtained using K_β filters, i.e. metal filters selected as having an absorption edge between the K_α and K_β wavelengths emitted by the tube.

Such a filter is usually inserted between the X-ray tube and the specimen. Another, more-and-more-commonly used way to obtain a monochromatic X-ray beam is via a large monochromator crystal (usually referred to as a 'monochromator'). This crystal is placed before or behind the specimen and diffracts the different characteristic peaks of the X-ray beam (i.e. K_α and K_β) at different angles, so that only one of them may be selected to enter into the detector. It is even possible to separate $K_{\alpha 1}$ and $K_{\alpha 2}$ radiations by using a specialised monochromator. Unfortunately, the gain in getting a monochromatic beam by using a filter or a monochromator is counteracted by a loss in intensity. Another way of separating K_α and K_β wavelengths is by using curved X-rays mirrors that can simultaneously monochromate and focus or parallelise the X-ray beam.

RADIATION PROTECTION. Exposure of any part of the human body to X-rays can be injurious to health. It is therefore essential that whenever X-ray equipment is used, adequate precautions are taken to protect the operator and any other person in the vicinity. Recommended practice for radiation protection as well as limits for the levels of X-radiation exposure are those established by national legislation in each country. If there are no official regulations or recommendations in a country, the latest recommendations of the International Commission on Radiological Protection should be applied.

SPECIMEN PREPARATION AND MOUNTING

The preparation of the powdered material and mounting of the specimen in a suitable holder are critical steps in many analytical methods, and are particularly so for XRPD analysis, since they can greatly affect the quality of the data to be collected[4]. The main sources of error due to specimen preparation and mounting are briefly discussed here for instruments in Bragg-Brentano parafocusing geometry.

[4] *Similarly, changes in the specimen can occur during data collection in the case of a non-equilibrium specimen (temperature, humidity).*

SPECIMEN PREPARATION

In general, the morphology of many crystalline particles tends to give a specimen that exhibits some degree of preferred orientation in the specimen holder. This is particularly evident for needle-like or plate-like crystals when size reduction yields finer needles or platelets. Preferred orientation in the specimen influences the intensities of various reflections, so that some are more intense and others are less intense, compared to what would be expected from a completely random specimen. Several techniques can be employed to improve randomness in the orientation of crystallites (and therefore to minimise preferred orientation), but further reduction of particle size is often the best and simplest approach. The optimum number of crystallites depends on the diffractometer geometry, the required resolution and the specimen attenuation of the X-ray beam. In some cases, particle sizes as large as 50 µm will provide satisfactory results in phase identification. However, excessive milling (crystallite sizes less than approximately 0.5 µm) may cause line broadening and significant changes to the sample itself such as:

— specimen contamination by particles abraded from the milling instruments (mortar, pestle, balls, etc.);
— reduced degree of crystallinity;
— solid-state transition to another polymorph;
— chemical decomposition;
— introduction of internal stress;
— solid-state reactions.

Therefore, it is advisable to compare the diffraction pattern of the non-ground specimen with that corresponding to a specimen of smaller particle size (e.g. a milled specimen). If the XRPD pattern obtained is of adequate quality considering its intended use, then grinding may not be required.

It should be noted that if a sample contains more than one phase and if sieving is used to isolate particles to a specific size, the initial composition may be altered.

SPECIMEN MOUNTING

Effect of specimen displacement

A specimen surface that is offset by D with reference to the diffractometer rotation axis causes systematic errors that are very difficult to avoid entirely; for the reflection mode, this results in absolute $D \cdot \cos\theta$ shifts[5] in 2θ positions (typically of the order of 0.01° in 2θ at low angles ($\cos\theta \simeq 1$) for a displacement D = 15 µm) and asymmetric broadening of the profile towards low 2θ values. Use of an appropriate internal standard allows the detection and correction of this effect simultaneously with that arising from specimen transparency. This is by far the largest source of errors in data collected on well-aligned diffractometers.

Effect of specimen thickness and transparency

When the XRPD method in reflection mode is applied, it is often preferable to work with specimens of 'infinite thickness'. To minimise the transparency effect, it is advisable to use a non-diffracting substrate (zero background holder), for example a plate of single crystalline silicon cut parallel to the 510 lattice planes[6]. One advantage of the transmission mode is that problems with sample height and specimen transparency are less important. The use of an appropriate internal standard allows the detection and correction of this effect simultaneously with that arising from specimen displacement.

CONTROL OF THE INSTRUMENT PERFORMANCE

Goniometers and the corresponding incident and diffracted X-ray beam optics have many mechanical parts that need adjustment. The degree of alignment or misalignment directly influences the quality of the results of an XRPD investigation. Therefore, the different components of the diffractometer must be carefully adjusted (optical and mechanical systems, etc.) to minimise adequately systematic errors, while optimising the intensities received by the detector. The search for maximum intensity and maximum resolution is always antagonistic when aligning a diffractometer. Hence, the best compromise must be sought whilst performing the alignment procedure. There are many different configurations and each supplier's equipment requires specific alignment procedures.

The overall diffractometer performance must be tested and monitored periodically using suitable certified reference materials. Depending on the type of analysis, other well-defined reference materials may also be employed, although the use of certified reference materials is preferred.

QUALITATIVE PHASE ANALYSIS (IDENTIFICATION OF PHASES)

The identification of the phase composition of an unknown sample by XRPD is usually based on the visual or computer-assisted comparison of a portion of its XRPD pattern to the experimental or calculated pattern of a reference material. Ideally, these reference patterns are collected on well-characterised single-phase specimens. This approach makes it possible in most cases to identify a crystalline substance by its 2θ diffraction angles or d-spacings and by its relative intensities. The computer-aided comparison of the diffraction pattern of the unknown sample to the comparison data can be based either on a more-or-less extended 2θ-range of the whole diffraction pattern or on a set of reduced data derived from the pattern. For example, the list of d-spacings and normalised intensities (I_{norm}), a so-called (d, I_{norm})-list extracted from the pattern, is the crystallographic fingerprint of the material, and can be compared to (d, I_{norm})-lists of single-phase samples compiled in databases.

For most organic crystals, when using Cu K_α radiation, it is appropriate to record the diffraction pattern in a 2θ-range from as near 0° as possible to at least 40°. The agreement in the 2θ-diffraction angles between specimen and reference is within 0.2° for the same crystal form, while relative intensities between specimen and reference may vary considerably due to preferred orientation effects. By their very nature, variable hydrates and solvates are recognised to have varying unit cell dimensions and as such shifting occurs in peak positions of the measured XRPD patterns for these materials. In these unique materials, variance in 2θ-positions of greater than 0.2° is not unexpected. As such, peak position variances such as 0.2° are not applicable to these materials. For other types of samples (e.g. inorganic salts), it may be necessary to extend the 2θ-region scanned to well beyond 40°. It is generally sufficient to scan past the 10 strongest reflections identified in single phase XRPD database files.

It is sometimes difficult or even impossible to identify phases in the following cases:

— non-crystallised or amorphous substances;

[5] *Note that a goniometer zero alignment shift would result in constant shift on all observed 2θ-line positions, in other words, the whole diffraction pattern is in this case translated by an offset of Z° in 2θ.*

[6] *In the case of a thin specimen with low attenuation, accurate measurements of line positions can be made with focusing diffractometer configurations in either transmission or reflection geometry. Accurate measurements of line positions on specimens with low attenuation are preferably made using diffractometers with parallel beam optics. This helps to reduce the effects of specimen thickness.*

— the components to be identified are present in low mass fractions of the analyte amounts (generally less than 10 per cent *m/m*);
— pronounced preferred orientation effects;
— the phase has not been filed in the database used;
— formation of solid solutions;
— presence of disordered structures that alter the unit cell;
— the specimen comprises too many phases;
— presence of lattice deformations;
— structural similarity of different phases;

QUANTITATIVE PHASE ANALYSIS

If the sample under investigation is a mixture of 2 or more known phases, of which not more than 1 is amorphous, the percentage (by volume or by mass) of each crystalline phase and of the amorphous phase can, in many cases, be determined. Quantitative phase analysis can be based on the integrated intensities, on the peak heights of several individual diffraction lines[7], or on the full pattern. These integrated intensities, peak heights or full-pattern data points are compared to the corresponding values of reference materials. These reference materials shall be single-phase or a mixture of known phases. The difficulties encountered during quantitative analysis are due to specimen preparation (the accuracy and precision of the results require in particular homogeneity of all phases and a suitable particle size distribution in each phase) and to matrix effects.
In favourable cases, amounts of crystalline phases as small as 10 per cent may be determined in solid matrices.

POLYMORPHIC SAMPLES

For a sample composed of 2 polymorphic phases a and b, the following expression may be used to quantify the fraction F_a of phase a:

$$F_a = \frac{1}{1 + K(I_b/I_a)}$$

The fraction is derived by measuring the intensity ratio between the 2 phases, knowing the value of the constant K. K is the ratio of the absolute intensities of the 2 pure polymorphic phases I_{oa}/I_{ob}. Its value can be determined by measuring standard samples.

METHODS USING A STANDARD

The most commonly used methods for quantitative analysis are:
— the 'external standard method';
— the 'internal standard method';
— the 'spiking method' (often also called the 'standard addition method').

The 'external standard method' is the most general method and consists of comparing the X-ray diffraction pattern of the mixture, or the respective line intensities, with those measured in a reference mixture or with the theoretical intensities of a structural model, if it is fully known.

To limit errors due to matrix effects, an internal reference material with crystallite size and X-ray absorption coefficient comparable to those of the components of the sample, and with a diffraction pattern that does not overlap at all that of the sample to be analysed, can be used. A known quantity of this reference material is added to the sample to be analysed and to each of the reference mixtures. Under these conditions, a linear relationship between line intensity and concentration exists. This application, called the 'internal standard method', requires a precise measurement of diffraction intensities.

In the 'spiking method' (or 'standard addition method'), some of the pure phase a is added to the mixture containing the unknown concentration of a. Multiple additions are made to prepare an intensity-versus-concentration plot in which the negative x intercept is the concentration of the phase a in the original sample.

ESTIMATE OF THE AMORPHOUS AND CRYSTALLINE FRACTIONS

In a mixture of crystalline and amorphous phases, the crystalline and amorphous fractions can be estimated in several ways. The choice of the method used depends on the nature of the sample:
— if the sample consists of crystalline fractions and an amorphous fraction of different chemical compositions, the amounts of each of the individual crystalline phases may be estimated using appropriate standard substances as described above; the amorphous fraction is then deduced indirectly by subtraction;
— if the sample consists of one amorphous and one crystalline fraction, either as a 1-phase or a 2-phase mixture, with the same elemental composition, the amount of the crystalline phase ('the degree of crystallinity') can be estimated by measuring 3 areas of the diffractogram:

A = total area of the peaks arising from diffraction from the crystalline fraction of the sample;
B = total area below area A;
C = background area (due to air scattering, fluorescence, equipment, etc).

When these areas have been measured, the degree of crystallinity can be roughly estimated using the following formula:

$$\% \text{ crystallinity} = 100A/(A + B - C)$$

It is noteworthy that this method does not yield absolute degree-of-crystallinity values and hence is generally used for comparative purposes only.

More sophisticated methods are also available, such as the Ruland method.

SINGLE CRYSTAL STRUCTURE

In general, the determination of crystal structures is performed from X-ray diffraction data obtained using single crystals. However, crystal structure analysis of organic crystals is a challenging task, since the lattice parameters are comparatively large, the symmetry is low and the scattering properties are normally very low.

For any given crystalline form of a substance, knowledge of the crystal structure allows the calculation of the corresponding XRPD pattern, thereby providing a 'preferred-orientation-free' reference XRPD pattern, which may be used for phase identification.

[7] *If the crystal structures of all components are known, the Rietveld method can be used to quantify them with good accuracy. If the crystal structures of the components are not known, the Pawley or least squares methods can be used.*

R. Porosity and Pore-size Distribution of Solids by Mercury Porosimetry

(Ph. Eur. method 2.9.32)

INTRODUCTION

In general, different types of pores may be pictured as apertures, channels or cavities within a solid body, or as space (i.e. interstices or voids) between solid particles in a bed, compact or aggregate. Porosity is a term that is often used to indicate the porous nature of solid material, and is more precisely defined as the ratio of the volume of accessible pores and voids to the total volume occupied by a given amount of the solid. In addition to the accessible pores, a solid may contain closed pores, which are isolated from the external surface and into which fluids are not able to penetrate. The characterisation of closed pores, i.e. cavities with no access to an external surface, is not covered in this chapter.

Porous materials may take the form of fine or coarse powders, compacts, extrudates, sheets or monoliths. Their characterisation usually involves the determination of the total pore volume or porosity as well as the pore-size distribution.

It is well established that the performance of a porous solid (e.g. its strength, reactivity, permeability or adsorbent power) is dependent upon its pore structure. Many different methods have been developed for the characterisation of pore structure. In view of the complexity of most porous solids, it is not surprising to find that the results obtained are not always in agreement and that no single technique can be relied upon to provide a complete picture of the pore structure. The choice of the most appropriate method depends on the application of the porous solid, its chemical and physical nature and the range of pore-size.

This chapter provides guidance for measurement of porosity and pore-size distribution by mercury porosimetry. It is a comparative test, usually destructive, in which the volume of mercury penetrating a pore or void is determined as a function of an applied hydrostatic pressure, which can be related to a pore diameter. Other information such as pore shape and inter-connectivity, the internal and external surface area, powder granulometry, bulk and tapped density could also be inferred from volume-pressure curves; however, these aspects of the technique do not fall under the scope of this chapter.

Practical considerations presently limit the maximum applied absolute pressure reached by some equipment to about 400 MPa, corresponding to a minimum equivalent pore diameter of approximately 0.003 µm. The maximum diameter will be limited for samples having a significant depth due to the difference in hydrostatic head of mercury from the top to the bottom of the sample. For most purposes this limit may be regarded as 400 µm.

Inter-particle and intra-particle porosity can be determined, but the method does not distinguish between these porosities where they co-exist.

The method is suitable for the study of most porous materials. Samples that amalgamate with mercury, such as certain metals, may be unsuitable for this technique or may require a preliminary passivation. Other materials may deform or compact under the applied pressure. In some cases it may be possible to apply sample-compressibility corrections and useful comparative data may still be obtained.

Mercury porosimetry is considered to be comparative, as for most porous media a theory is not available to allow an absolute calculation of results of pore-size distribution. Therefore this technique is mainly recommended for development studies.

Mercury is toxic. Appropriate precautions must be observed to safeguard the health of the operator and others working in the area. Waste material must also be disposed of in a suitable manner, according to local regulations.

PRINCIPLE

The technique is based on the measurement of the mercury volume intruded into a porous solid as a function of the applied pressure. The measurement includes only those pores into which mercury can penetrate at the pressure applied.

A non-wetting liquid penetrates into a porous system only under pressure. The pressure to be applied is in inverse proportion to the inner diameter of the pore aperture. In the case of cylindrical pores, the correlation between pore diameter and pressure is given by the Washburn equation:

$$d_p = -\frac{4 \cdot \sigma}{p} \cos\theta$$

d_p = pore diameter, in metres;
σ = surface tension, in newtons per metre;
θ = contact angle of mercury on the sample, in degrees;
p = applied pressure, in pascals.

APPARATUS

The sample holder, referred to as penetrometer or dilatometer, has a calibrated capillary tube, through which the sample can be evacuated and through which mercury can enter. The capillary tube is attached to a wider tube in which the test sample is placed. The change in the volume of mercury intruded is usually measured by the change in capacitance between the mercury column in the capillary tube and a metal sleeve around the outside of the capillary tube. If precise measurements are required the expected total void and pore volume of the sample should be between 20 per cent and 90 per cent of the internal volume of the capillary tube. Since different materials exhibit a wide range of open porosities, a number of penetrometers with different capillary tube diameters and sample volumes may be required. A typical set-up for a mercury porosimeter instrument is given in Figure 2.9.32.-1. The porosimeter may have separate ports for high- and low-pressure operation, or the low-pressure measurement may be carried out on a separate unit.

The pressure range is typically 4-300 kPa for low-pressure operation and above 300 kPa for high-pressure operation, depending on the design of the particular apparatus and on the intended use.

METHOD

Sample preparation

The sample is pre-treated to remove adsorbed material that can obscure its accessible porosity, for example by heating and/or evacuation, or by flowing inert gas. It may be possible to passivate the surface of wettable or amalgam-forming solids, for example by producing a thin layer of oxide, or by coating with stearate.

The sample of the pre-treated solid is weighed and transferred to the penetrometer. The pore system of the sample is then degassed in a vacuum to a maximum residual pressure of 7 Pa.

M. Mercury
N. Sample

Figure 2.9.32.-1. – *Example of the set-up of a mercury porosimeter instrument*

Filling the penetrometer with mercury

The mercury used is of analytical quality. Overlay the sample with mercury under vacuum. The vacuum is required to ensure the transfer of mercury from the reservoir to the penetrometer. In a filled penetrometer the filling pressure comprises the applied pressure plus the pressure contribution created by the head of mercury contacting the sample. A typical filling pressure would be about 4 kPa. The hydrostatic pressure of the mercury over the sample may be minimised by filling the penetrometer in the horizontal position.

Low-pressure measurement

Admit air or nitrogen in a controlled manner to increase the pressure either in stages corresponding to the particular pore sizes of interest, or continuously at a slow rate. The concomitant change in the length of the mercury column in the capillary tube is recorded. When the maximum required pressure has been reached, return to atmospheric pressure.

High-pressure measurement

After measurement at low pressure, the penetrometer filled with mercury is transferred to the high-pressure port or unit of the instrument and overlaid with hydraulic fluid. Mercury is intruded into the pore system via the hydraulic fluid. Increase the pressure in the system to the maximum pressure reached in the low-pressure measurement and record the intrusion volume at this pressure, since subsequent intrusion volumes are calculated from this initial volume. Increase the pressure either in stages corresponding to the particular pore sizes of interest, or continuously at a slow rate. The fall in the mercury column is measured up to the maximum required pressure. If required the pressure may be decreased either in stages or continuously at a slow rate to determine the mercury extrusion curve.

Corrections are made to take account of changes in the volume of the mercury, the penetrometer and other components of the volume detector system under elevated pressure. The extent of the corrections may be determined by means of blank measurements under the same conditions.

An experimentally determined volume-pressure curve is shown in Figure 2.9.32.-2.

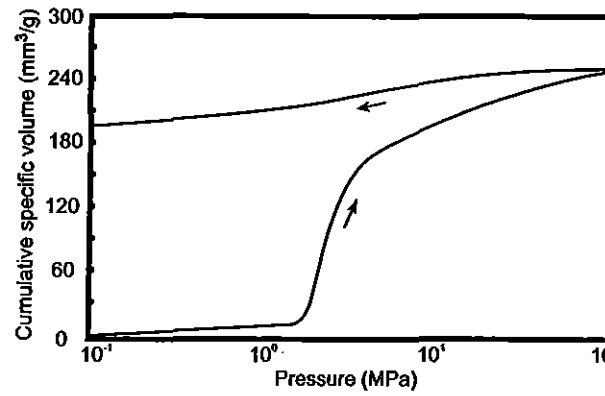

Figure 2.9.32.-2. – *Volume-pressure curve as semilogarithmic plot*

REPORTING OF RESULTS

The pressure readings can be converted to pore diameters by means of the Washburn equation or by another model.

The surface tension of mercury (σ) depends not only on the temperature, but also, in the case of markedly curved surfaces areas, on the radius of curvature. In general, values between 0.41 $N \cdot m^{-1}$ and 0.52 $N \cdot m^{-1}$ are measured at room temperature. If the value is not known, σ = 0.48 $N \cdot m^{-1}$ can be used.

The contact angle of mercury (θ) in most cases is more than 90°. It may be determined using a contact angle instrument. If the value is not known, θ = 130° can be used. The values of contact angle and surface tension and the model used in the calculation are reported.

Visualisation of the data can be done with several types of graphs. Frequently, in a graphical representation the pore diameter is plotted on the abscissa and the intruded volume

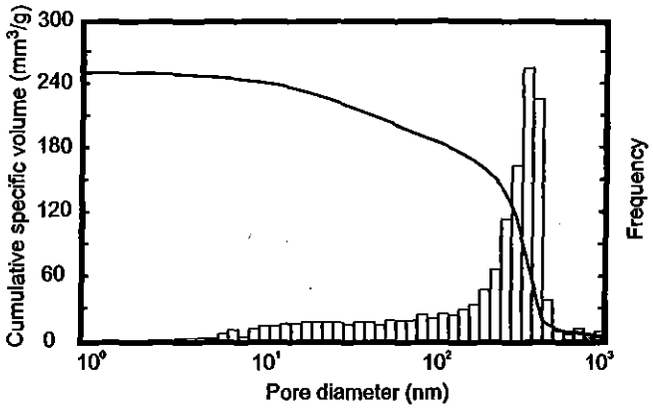

Figure 2.9.32.-3. – *Pore-size distribution as semilogarithmic plots of the cumulative and the normalised density distribution*

per sample mass on the ordinate to give the pore-size distribution. It is appropriate here to choose a logarithmic scale for the abscissa (see Figure 2.9.32.-3). The spaces between the particles of the solid sample are included as pores in the calculation. If the pores differ in size from the voids, the latter can be separated by choosing the appropriate pore-size range.

Extrusion curves may not be used for calculating the pore-size distribution (for hysteresis, see Figure 2.9.32.-2), because an intruded part of the mercury always remains in the pore system. The retention ratio may however be useful for the qualitative characterisation of pores that are only accessible via narrow openings ('ink-bottle pores').

Most common characteristic values, such as the total intruded specific volume and the mean and median pore diameters, are calculated from the pore-size distribution. Moreover, sufficient information must be documented about the sample, the sample preparation, the evacuation conditions and the instrument used.

CONTROL OF INSTRUMENT PERFORMANCE

As mercury porosimetry is considered to be used as a comparative test, no details are given in this chapter. However, it is recommended that a stable comparison material is tested on a regular basis to monitor instrument calibration and performance.

S. Bulk Density and Tapped Density of Powders[1]

(Ph. Eur. method 2.9.34)

BULK DENSITY

The bulk density of a powder is the ratio of the mass of an untapped powder sample to its volume, including the contribution of the interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the spatial arrangement of particles in the powder bed. The bulk density is expressed in grams per millilitre despite the International Unit being kilogram per cubic metre (1 g/mL = 1000 kg/m^3), because the measurements are made using cylinders. It may also be expressed in grams per cubic centimetre.

The bulking properties of a powder are dependent upon the preparation, treatment and storage of the sample, i.e. how it has been handled. The particles can be packed to have a range of bulk densities and, moreover, the slightest disturbance of the powder bed may result in a changed bulk density. Thus, the bulk density of a powder is often very difficult to measure with good reproducibility and, in reporting the results, it is essential to specify how the determination was made.

The bulk density of a powder is determined either by measuring the volume of a known mass of powder sample, which may have been passed through a sieve, in a graduated cylinder (Method 1), or by measuring the mass of a known volume of powder that has been passed through a volumeter into a cup (Method 2) or has been introduced into a measuring vessel (Method 3).

Methods 1 and 3 are favoured.

METHOD 1: MEASUREMENT IN A GRADUATED CYLINDER

Procedure Pass a quantity of powder sufficient to complete the test through a sieve with apertures greater than or equal to 1.0 mm, if necessary, to break up agglomerates that may have formed during storage; this must be done gently to avoid changing the nature of the material. Into a dry, graduated, 250 mL cylinder (readable to 2 mL), gently introduce, without compacting, approximately 100 g (m) of the test sample weighed with 0.1 per cent accuracy.

If necessary, carefully level the powder without compacting, and read the unsettled apparent volume (V_0) to the nearest graduated unit. Calculate the bulk density in grams per millilitre using the formula m/V_0. Generally, replicate determinations are desirable for the determination of this property.

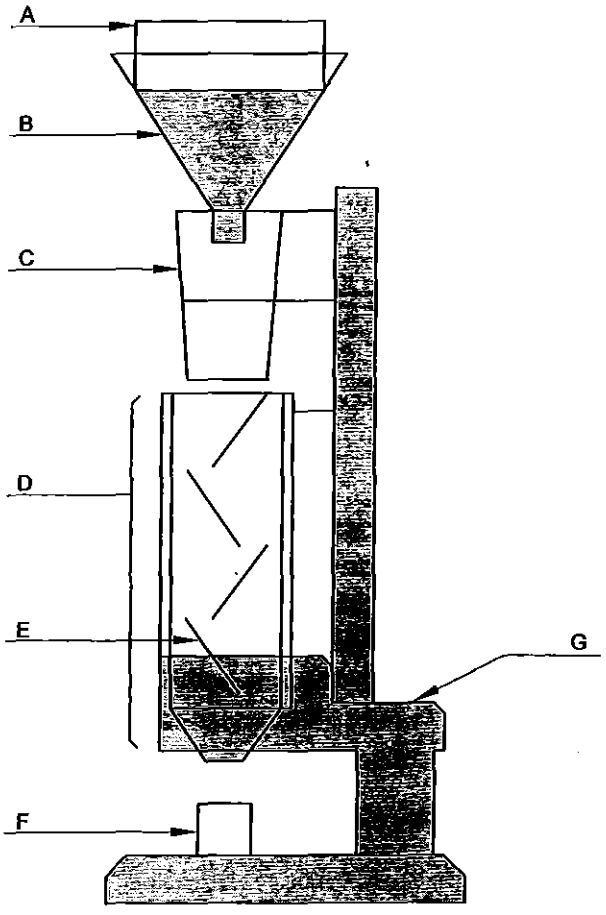
If the powder density is too low or too high, such that the test sample has an untapped apparent volume of more than 250 mL or less than 150 mL, it is not possible to use 100 g of powder sample. In this case, a different amount of powder is selected as the test sample, such that its untapped apparent volume is between 150 mL and 250 mL (apparent volume greater than or equal to 60 per cent of the total volume of the cylinder); the mass of the test sample is specified in the expression of results.

For test samples having an apparent volume between 50 mL and 100 mL, a 100 mL cylinder readable to 1 mL can be used; the volume of the cylinder is specified in the expression of results.

[1] *This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8. Pharmacopoeial harmonisation.*

METHOD 2: MEASUREMENT IN A VOLUMETER

Apparatus The apparatus (Figure 2.9.34.-1) consists of a top funnel fitted with a 1.0 mm sieve, mounted over a baffle box containing 4 glass baffles over which the powder slides and bounces as it passes. At the bottom of the baffle box is a funnel that collects the powder and allows it to pour into a cup mounted directly below it. The cup may be cylindrical (25.00 ± 0.05 mL volume with an internal diameter of 30.00 ± 2.00 mm) or cubical (16.39 ± 0.20 mL volume with internal dimensions of 25.400 ± 0.076 mm).



A. 1.0 mm sieve
B. powder funnel
C. loading funnel
D. baffle box
E. glass baffle
F. cup
G. stand

Figure 2.9.34.-1. – *Volumeter*

Procedure Allow an excess of powder to flow through the apparatus into the sample receiving cup until it overflows, using a minimum of 25 cm^3 of powder with the cubical cup and 35 cm^3 of powder with the cylindrical cup. Carefully, scrape excess powder from the top of the cup by smoothly moving the edge of the blade of a spatula perpendicular to and in contact with the top surface of the cup, taking care to keep the spatula perpendicular to prevent packing or removal of powder from the cup. Remove any material from the side of the cup and determine the mass (M) of the powder to the nearest 0.1 per cent. Calculate the bulk density in grams per millilitre using the formula M/V_0 (where V_0 is the volume of the cup) and record the average of 3 determinations using 3 different powder samples.

METHOD 3: MEASUREMENT IN A VESSEL

Apparatus The apparatus consists of a 100 mL cylindrical vessel of stainless steel with dimensions as specified in Figure 2.9.34.-2.

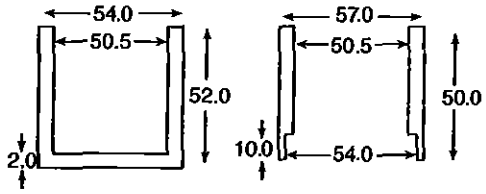


Figure 2.9.34.-2. – *Measuring vessel (left) and cap (right) Dimensions in millimetres*

Procedure Pass a quantity of powder sufficient to complete the test through a 1.0 mm sieve, if necessary, to break up agglomerates that may have formed during storage, and allow the obtained sample to flow freely into the measuring vessel until it overflows. Carefully scrape the excess powder from the top of the vessel as described under Method 2. Determine the mass (M_0) of the powder to the nearest 0.1 per cent by subtracting the previously determined mass of the empty measuring vessel. Calculate the bulk density in grams per millilitre using the formula $M_0/100$ and record the average of 3 determinations using 3 different powder samples.

TAPPED DENSITY

The tapped density is an increased bulk density attained after mechanically tapping a receptacle containing the powder sample.

The tapped density is obtained by mechanically tapping a graduated measuring cylinder or vessel containing the powder sample. After observing the initial powder volume or mass, the measuring cylinder or vessel is mechanically tapped, and volume or mass readings are taken until little further volume or mass change is observed. The mechanical tapping is achieved by raising the cylinder or vessel and allowing it to drop, under its own mass, a specified distance by one of 3 methods as described below. Devices that rotate the cylinder or vessel during tapping may be preferred to minimise any possible separation of the mass during tapping down.

METHOD 1

Apparatus The apparatus (Figure 2.9.34.-3) consists of the following:

— a 250 mL graduated cylinder (readable to 2 mL) with a mass of 220 ± 44 g;

— a settling apparatus capable of producing, per minute, either nominally 250 ± 15 taps from a height of 3 ± 0.2 mm, or nominally 300 ± 15 taps from a height of 14 ± 2 mm. The support for the graduated cylinder, with its holder, has a mass of 450 ± 10 g.

Procedure Proceed as described above for the determination of the bulk volume (V_0). Secure the cylinder in the support. Carry out 10, 500 and 1250 taps on the same powder sample and read the corresponding volumes V_{10}, V_{500} and V_{1250} to the nearest graduated unit. If the difference between V_{500} and V_{1250} is less than or equal to 2 mL, V_{1250} is the tapped volume. If the difference between V_{500} and V_{1250} exceeds 2 mL, repeat in increments of, for example, 1250 taps, until the difference between successive measurements is less than or equal to 2 mL. Fewer taps may be appropriate for some powders, when validated. Calculate

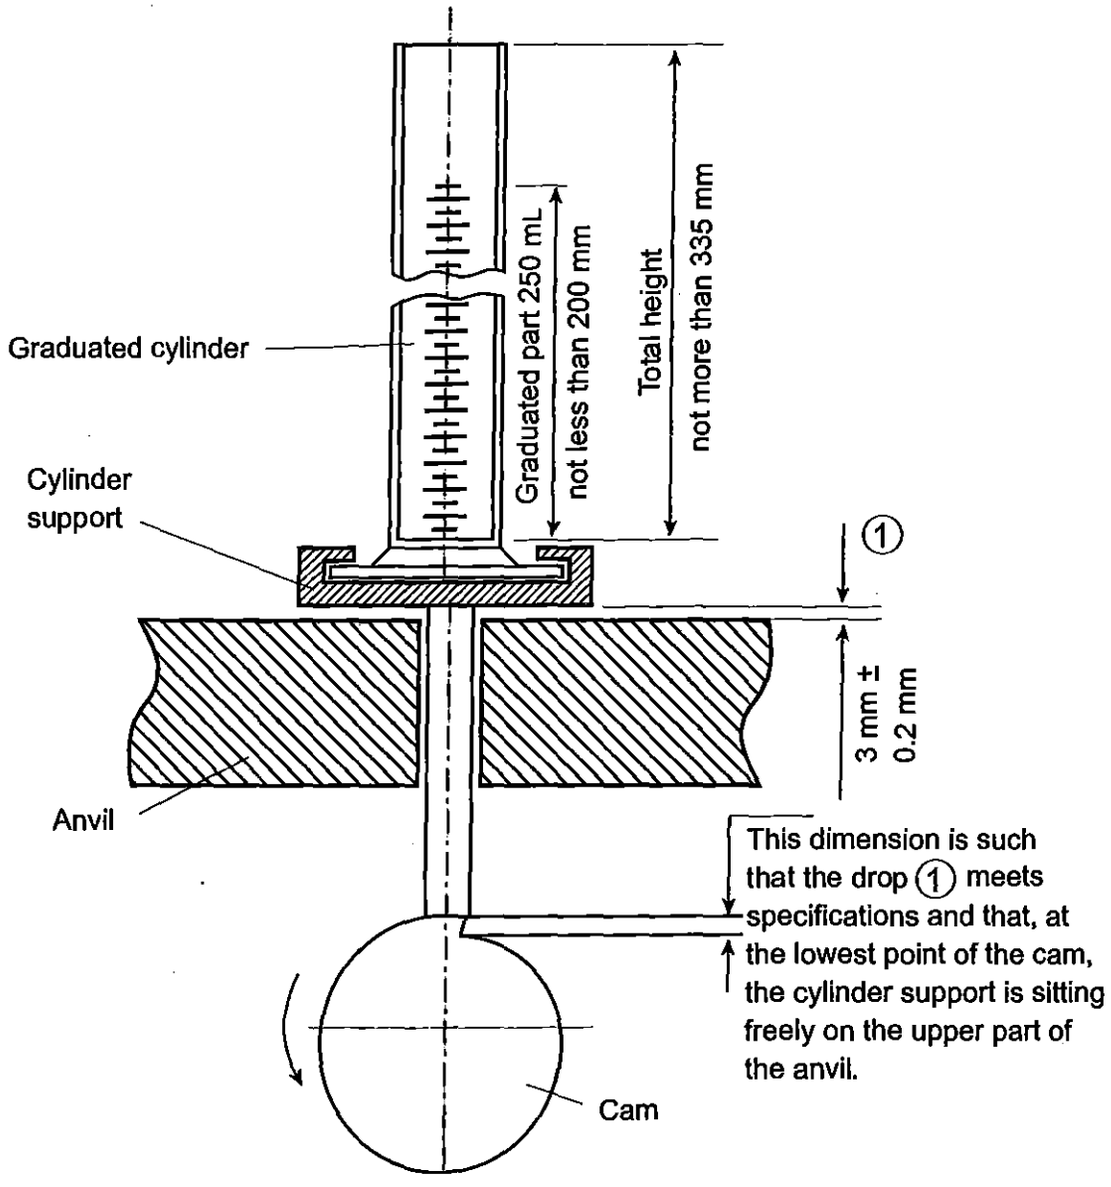

Figure 2.9.34.-3. – *Settling device for powder samples*
Dimensions in millimetres

the tapped density in grams per millilitre using the formula m/V_f (where V_f is the final tapped volume). Generally, replicate determinations are desirable for the determination of this property. Specify the drop height with the results.

If it is not possible to use a 100 g test sample, use a reduced amount and a suitable 100 mL graduated cylinder (readable to 1 mL) weighing 130 ± 16 g and mounted on a support weighing 240 ± 12 g. If the difference between V_{500} and V_{1250} is less than or equal to 1 mL, V_{1250} is the tapped volume. If the difference between V_{500} and V_{1250} exceeds 1 mL, repeat in increments of, for example, 1250 taps, until the difference between successive measurements is less than or equal to 1 mL. The modified test conditions are specified in the expression of the results.

METHOD 2

Procedure Proceed as directed under Method 1 except that the mechanical tester provides a fixed drop of 3 ± 0.2 mm at a nominal rate of 250 taps per minute.

METHOD 3

Procedure Proceed as described under Method 3 for measuring the bulk density, using the measuring vessel equipped with the cap shown in Figure 2.9.34.-2. The measuring vessel with the cap is lifted 50-60 times per minute by the use of a suitable tapped density tester. Carry out 200 taps, remove the cap and carefully scrape excess powder from the top of the measuring vessel as described under Method 3 for measuring the bulk density. Repeat the procedure using 400 taps. If the difference between the 2 masses obtained after 200 and 400 taps exceeds 2 per cent, repeat the test using 200 additional taps until the difference between successive measurements is less than 2 per cent. Calculate the tapped density in grams per millilitre using the formula $M_f/100$ (where M_f is the mass of powder in the measuring vessel). Record the average of 3 determinations using 3 different powder samples. The test conditions, including tapping height, are specified in the expression of the results.

MEASURES OF POWDER COMPRESSIBILITY

Because the interparticulate interactions influencing the bulking properties of a powder are also the interactions that interfere with powder flow, a comparison of the bulk and tapped densities can give a measure of the relative importance of these interactions in a given powder. Such a comparison is often used as an index of the ability of the powder to flow, for example the compressibility index or the Hausner ratio.

The compressibility index and Hausner ratio are measures of the propensity of a powder to be compressed as described above. As such, they are measures of the powder's ability to settle, and they permit an assessment of the relative importance of interparticulate interactions. In a free-flowing powder, such interactions are less significant, and the bulk and tapped densities will be closer in value. For more-poorly flowing materials, there are frequently greater interparticulate interactions, and a greater difference between the bulk and tapped densities will be observed. These differences are reflected in the compressibility index and the Hausner ratio.

Compressibility index:

$$\frac{100(V_0 - V_f)}{V_0}$$

V_0 = unsettled apparent volume;
V_f = final tapped volume.

Hausner Ratio:

$$\frac{V_0}{V_f}$$

Depending on the material, the compressibility index can be determined using V_{10} instead of V_0. If V_{10} is used, it is clearly stated with the results.

T. Wettability of Porous Solids Including Powders

(Ph. Eur. method 2.9.45)

INTRODUCTION

The wettability of solid surfaces is commonly characterised by direct or indirect contact angle measurements.

The contact angle (θ) between a liquid and a solid is the angle naturally formed when a drop of a liquid is placed on a solid surface. This is depicted in Figure 2.9.45.-1. For a given liquid, wettable solids show a low contact angle and non-wettable solids show a contact angle of 90° or more.

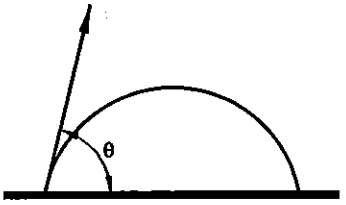

Figure 2.9.45.-1. – *Contact angle (θ) of a sessile drop observed on a non-porous surface*

2 methods for the determination of wettability are described below. The methods are capable of measuring the wettability of porous solids like powders or granules. Both methods express the wettability by a contact angle measurement between the porous solid and a given liquid.

The sessile drop method is based on direct measurement of a contact angle of a sessile drop on a compacted powder disc.

With the Washburn method the contact angle is indirectly measured. The method is based on the capillary effect of the powder pores. The effect (mass gain) is recorded by special electronic balances starting the moment when the powder sample touches the surface of a liquid, preferably not dissolving or poorly dissolving the sample. The measurement has very little or no effect on the state of the powder.

Any pre-treatment of the sample to be examined is disadvantageous, since the properties may be significantly altered. For example, the compaction of a powder as a disc may decrease the surface free energy when the crystalline state of the powder is changed (e.g. metastable forms), or may increase surface free energy by creating crystal defects (disadvantage of the sessile drop method since compacted powder discs are tested).

The methods are usually applied to examine the following parameters:

— batch-to-batch consistency of samples in terms of wettability;
— effect of liquid viscosity on wettability;
— effect of surface tension of a liquid on wettability;
— alteration of surface properties of samples.

SESSILE DROP METHOD

This method may be used to characterise directly the wettability of coatings and compacted formulations such as tablets. Moreover, it is sometimes possible to use the sessile drop instrument in a dynamic measurement (dynamic contact angle measurement, Figure 2.9.45.-2) of porous solid/liquid systems where the contact angle decreases. By taking several contact angle measurements as a function of time, the rate of spreading accompanied by penetration of a liquid droplet into a slightly porous solid may be studied.

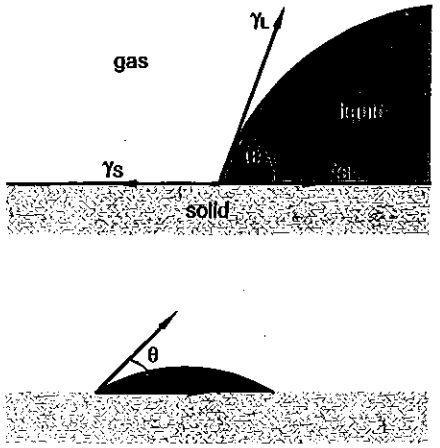

Figure 2.9.45.-2. – *Sessile drop determination with visual inspection of the droplet*

Under equilibrium conditions the contact angle of a sessile drop depends on 3 interrelated surface tensions and is determined using Young's equation (see Figure 2.9.45.-2, 1st part):

$$\gamma_S = \gamma_{SL} + \gamma_L \cos\theta$$

γ_S = surface tension of the solid with air;
γ_{SL} = interfacial tension of the solid with the liquid;
γ_L = surface tension of the liquid with air.

PROCEDURE

Since powders are unable to form a completely flat surface, the powder is usually compacted as a disc in an attempt to make the surface smoother. A liquid drop with a given volume is placed on the disc (see Figure 2.9.45.-2) allowing direct measurement of the contact angle using a goniometer fitted with an eyepiece protractor, or by geometric construction on a photomicrograph. Other physical and mathematical procedures of data analysis may also be appropriate. The drop volume may influence the result. Several determinations of the contact angle (θ) (n = 6) are usually carried out and the average is calculated.

WASHBURN METHOD

The Washburn method is able to measure the contact angle of porous solids with a contact angle in the range of 0-90°.

The tested material is the combination of the sample, the holder and the filter system. Therefore, an estimation or determination of the true value is not possible and only apparent values of the contact angle can be determined. However, the contact angle of the sample is the functional property on which the result is significantly dependent. The outcome of the test is a ranking order listing the wettability of different substances or formulations characterised by an apparent contact angle.

PRINCIPLE

If a porous solid is brought into contact with a liquid, such that the solid is not submerged in the liquid, but rather is just touching the liquid surface, then the rise of liquid into the pores of the solid due to capillary action will be governed by the following equations:

$$m^2 = \frac{t}{A} \qquad (1)$$

m = mass of liquid sucked into the solid;
t = time elapsed since the solid and the liquid were brought into contact;
A = constant, dependent on the properties of the liquid and the solid to be examined, calculated using the following equation:

$$A = \frac{\eta}{c \times \rho^2 \times \gamma \times \cos\theta} \qquad (2)$$

η = viscosity of the liquid;
ρ = density of the liquid;
γ = surface tension of the liquid;
θ = contact angle between the solid and the liquid;
c = material constant, dependent on the porous texture of the solid.

Equations (1) and (2) lead to equation (3):

$$\cos\theta = \frac{m^2}{t} \times \frac{\eta}{c \times \rho^2 \times \gamma} \qquad (3)$$

In setting up a Washburn determination, a liquid with known density (ρ), viscosity (η), and surface tension (γ) is used. Under these conditions, when the mass of liquid rising into the porous solid is monitored as a function of time (such that capillary penetration rate ($\frac{m^2}{t}$) is the experimental data), 2 unknowns remain according to equation (3): the contact angle (θ) of the liquid on the solid, and the solid material constant (c).

Determination of the material constant (c)

The material constant for a porous solid is determined by the following equation, considering cylindrical pores:

$$\frac{\pi^2 \times r^5 \times N^2}{2} \qquad (4)$$

r = average capillary radius within the porous solid;
N = number of capillaries per volumetric unit.

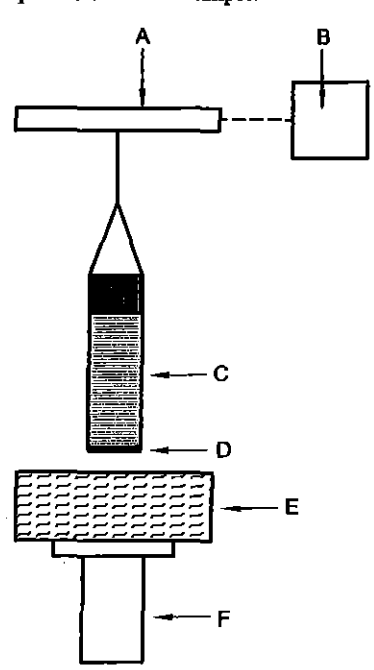
If a Washburn determination is performed with a liquid considered to have a contact angle of 0° (cos 0° = 1) on the solid, then the solid material constant (c) is the only remaining unknown in equation (3) and can thus be determined. *n*-Heptane is the liquid of choice for determining material constants because of its low surface tension (20.14 $mN \cdot m^{-1}$ at 25 °C). *n*-Hexane may also be used (18.43 $mN \cdot m^{-1}$ at 25 °C) but is more volatile. If the powder dissolves too quickly in these liquids, hexamethyldisiloxane may be used instead (15.9 $mN \cdot m^{-1}$ at 25 °C). Replicate determinations are performed (n = 6) and the average value calculated.

Once the material constant (c) has been determined for the solid to be examined, a sample of the solid can be tested for wettability by another liquid. The material constant determined by the *n*-heptane test is used in the Washburn equation, in combination with the capillary penetration rate ($\frac{m^2}{t}$) data obtained while testing the substance to be examined in the prescribed liquid. This allows calculation of the contact angle.

NOTE: if a series of liquids (at least 2 liquids in addition to the liquid used to determine the material constant) is tested against a given solid then the resultant contact angle data can be used to calculate the surface energy of the porous solid.

APPARATUS

Figure 2.9.45.-3 shows the principal components of the apparatus. The main device is an electronic balance with a suitable processor ensuring a suitable resolution in force measurement and a suitable resolution in lifting up the immersion liquid towards the sample.



A. electronic balance
B. computer
C. sample holder
D. filter
E. immersion liquid
F. lift

Figure 2.9.45.-3. – *Apparatus for contact angle measurement by the Washburn method*

Table 2.9.45.-1 indicates parameters of the electronic balance that are generally considered suitable.

Table 2.9.45.-1. – *Technical parameters of the electronic balance*

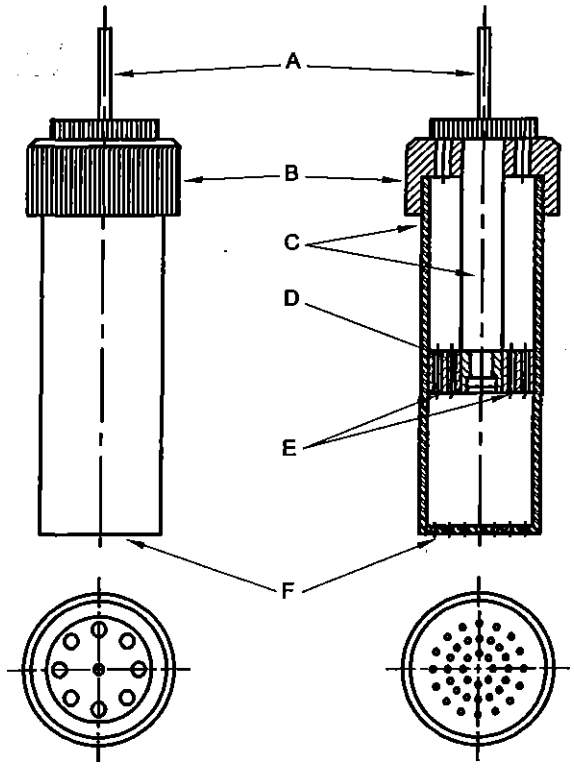
	Lift	Mass measurement
Range	> 110 mm	0 - 210 g
Resolution	0.1 µm	10 µg
Speed	0.099 - 500 mm/min	-

Sample holders

The sample holder may be a small glass cylinder with a sintered-glass filter at one end.

Powder material holders (see Figure 2.9.45-4) may also be made of aluminium; they are less fragile than those made of glass and have small holes in the bottom that render them easier to clean than a sintered-glass filter. The cover for the cell is equipped with 2 screw threads. One connects it with the sample chamber while the other allows the user to guide a piston down onto the sample itself and compact it.

The apparatus is similar to an automatic tensiometer, except for the sample holder.



A. fixing C. thread E. capillary holes
B. cover D. plunger F. capillary holes

Figure 2.9.45.-4. – *Example of sample holder with plunger for compaction of a powder*

PROCEDURE

Filling of the sample holder

Place a disc of filter paper in the bottom of the aluminium or glass sample holder. This prevents powder from leaking out of the bottom of the cell. The filter does not have to be made of paper, but it must be a material that is easily wetted by the liquid to be tested. A black-band filter (used for reverse osmosis) is recommended because of its high porosity and minimum flow resistance.

Place a known amount of powder into the cell.

The reproducibility of material constants and contact angles will depend on the ability to weigh out the same amount of powder for each test when a sufficient and adjusted amount of powder is compacted in a uniform way (i.e. tapping/compaction of the powder).

For most powders, a correct amount is in the range of a few grams, typically filling about 2/3 of the capacity of the holder. Place a second piece of filter paper on top of the powder in the cell. This will prevent powder from rising through the holes in the piston during the compaction process and/or during the determination.

Tapping/compaction of the powder

A bulk powder bed is very porous and thus very sensitive to small influences that can easily alter the porosity and consequently the *c*-constant. Therefore a tapped powder may be advantageous and will show more reproducible results. The appropriate number of taps must first be evaluated: 50-100 taps are usually appropriate.

If the aluminium sample holder is used then it may be mounted in the cylinder of a stamp volumeter, which can run the evaluated number of taps.

If tapping is not appropriate, the powder bed is compacted by screwing the piston of the aluminium sample holder applying a specified pressure.

A further possibility is centrifugation under defined conditions. Where applicable, a compacted disc of the powder sample may also be mounted on the electronic balance. A sample holder is omitted in this case.

After connecting to the balance, the sample holder is positioned with the porous solid just above the surface of the liquid (see Figure 2.9.45.-3), using the lift.

The liquid is raised further until it just touches the bottom of the porous sample. Mass-versus-time data is then collected as liquid penetrates into the solid. Data can be presented in either graphical or tabular format. The apparatus may perform the whole determination automatically.

CRITICAL PARAMETERS

The following points must be considered.

Sample properties:

— water content of the sample;
— crystalline or solid-state properties of the sample (polymorphic form, type of solvate).

Sample preparation:

— homogeneity of any powder blend to be examined;
— particle-size distribution; before testing it is sometimes advisable to sieve the sample (e.g. using a 250 µm sieve);
— the optimal compaction parameters (amount of sample, number of taps or piston mass) must be determined;
— the compaction state of the different powder samples must be uniform;
— the sample holder or, if used, the glass frit must be carefully cleaned;
— uniformity of the results is improved by using a sample holder made of aluminium.

Immersion liquid:

— specifications of the immersion liquid must be indicated.

U. Crystallinity

(Ph. Eur. general texts 5.16)

This chapter provides general information on crystallinity and refers to the various techniques described in the European Pharmacopoeia that are used for its determination.

INTRODUCTION - THE CONCEPT OF CRYSTALLINITY

Most organic and inorganic compounds of pharmaceutical relevance exist as a solid material, which can be characterised by a structure located between a perfectly ordered crystal and an amorphous material.

Real crystals lie somewhere between an ideal crystal state and the amorphous state. The position of a crystal on a scale bounded by these 2 extremes is termed its crystallinity.

A perfectly ordered crystal is an ideal state that is seldom, if ever, achieved. The structural units of a crystal, termed unit cells, are repeated regularly and indefinitely in 3 dimensions in space. The unit cell has a definite orientation and shape defined by the translational vectors *a*, *b* and *c*, and the angles α, β and γ, and hence has a definite volume, *V*, that contains the atoms and molecules necessary for forming the crystal. A crystalline system is defined by 3 long-range order symmetry operators (translational, orientational and conformational); the various mesophases (liquid crystals, crystals and plastic crystals) have 1 or 2 of the long-range symmetry operators and the ideal amorphous state is defined by the absence of all 3 operators.

Each crystal can be classified as a member of one of 7 possible crystal systems that are defined by the relationships between the individual dimensions *a*, *b* and *c* and between the individual angles α, β and γ of the unit cell. The structure of a given crystal may be classified according to one of the 7 crystal systems, to one of the 14 Bravais lattices and to one of the 230 space groups. All the 230 possible space groups, their symmetries and the symmetries of their diffraction patterns are compiled in the International Tables for Crystallography.

Many substances are capable of crystallising in more than one type of crystal lattice, which is known as polymorphism. The occurrence of polymorphism is a common phenomenon among organic molecules, giving rise to different physico-chemical properties. Crystalline polymorphs have the same chemical composition but different internal crystal structures and, therefore, possess different physico-chemical properties. The different crystal structures in polymorphs are due to different atomic packing arrangements and/or different conformations of the molecules (see chapter *5.9. Polymorphism*).

The other extreme of a crystal state is the ideal or true amorphous state, where all long-range order is lost. For most organic systems certain short-range order remains, but this is not expected to extend over distances much larger than nearest neighbour (NN) or next nearest neighbour (NNN) interactions, which are typically less than 2-2.5 nm for small organic molecules.

Amorphous material is characterised by the absence of distinct reflections in the X-ray powder diffraction (XRPD) pattern (*2.9.33*).

The crystallinity of a real powder can be considered by 2 models of crystallinity. In the 1-state model all particles will be of the same crystallinity whereas in the 2-state model each particle can be either crystalline or amorphous, such that the actual crystallinity of the powder is the weighted average of these 2 extreme crystallinities. Such a powder is obtained when pure crystalline and amorphous phases are physically mixed. In reality, a powder probably contains particles with different degrees of crystallinity, just as it may contain particles with different sizes and shapes.

The extent of disorder in a crystalline solid can affect many physico-chemical properties of substances for pharmaceutical use. Because of the great relevance of these properties, it is important to be able to assess the extent of disorder or the crystallinity of a solid by a suitable quantitative method.

METHODS FOR MONITORING AND DETERMINING CRYSTALLINITY

Various methods are available for determining the crystallinity of a solid. Many techniques cannot detect or quantify these properties independently; for this reason, it is useful to combine several of the methods described below. Such methods often do not give accurate results and limits of quantitation are usually much greater than those for chemical impurities. In addition, certain assumptions have to be made about the relationship between standards used for calibration, which are typically mixtures of crystalline and amorphous particles (2-state model), and the samples to be analysed that are likely to have at least a small component of material exhibiting 1-state model behaviour. Finally, the lack of well-defined standards for 100 per cent crystalline or 100 per cent amorphous material complicates the validation of such methods. As explained above, it is obvious that different amorphous or non-crystalline phases exist and even co-exist in a solid powder. These different non-crystalline forms of a solid can give different responses depending on the techniques used for determining the degree of crystallinity.

X-ray powder diffraction (*2.9.33*)

XRPD is still the most commonly used method for determining the degree of crystallinity, although this method suffers from some limitations due to peak broadening, amorphous halo and preferred orientation, which make interpretation and quantitation difficult.

XRPD alone is often insufficient to distinguish between the different non-crystalline phases. The X-ray diffraction pattern of a purely amorphous and nanocrystalline phase is characteristic of a broad diffuse halo. In-depth analysis of the X-ray diffraction patterns will show that the diffuse halo in the pattern of nanocrystalline material shows some correlation to the pattern of the parent crystalline phase, while in the case of a pure amorphous phase such a correlation does not exist. Additional techniques may be required to establish the true nature of X-ray amorphous materials.

Thermal analysis

Thermal analysis (*2.2.34*) of crystalline materials exhibits a melting transition that is often accompanied by decomposition or evaporation of solvents. In the case of true amorphous materials, thermal analysis reveals a glass transition, whereas only a melt would be expected for a nanocrystalline material.

Microcalorimetry (*2.2.61*)

It is a highly sensitive technique which allows the determination of the rate and extent of chemical reactions, changes of phase or changes of structure. Amorphous parts of a substance can recrystallise by subjecting the sample to higher relative humidity or an atmosphere containing organic vapour. The measurement of the heat of recrystallisation enables the amorphous content to be determined from the enthalpy of recrystallisation. By relating the output from the microcalorimeter for a sample to that obtained for an

amorphous standard, it is possible to quantify the amorphous content of the sample. The range of amorphous content covered by this method depends on the individual substance to be tested; in favourable cases limits of detection below 1 per cent can be reached.

Solution calorimetry (*2.2.61*)
Solution calorimetry provides a means of determining enthalpy of solution for a solid substance. The crystallinity of the solid sample to be examined is given by the enthalpy of solution of the solid sample ($\Delta H_x^!$) minus the enthalpy of solution of the chosen reference standard of the same substance ($\Delta H_r^!$) when determined under the same conditions. Because the reference standard is usually chosen for its perceived high crystallinity, its enthalpy of solution is usually algebraically greater (more endothermic or less exothermic) than that of the solid sample to be examined in the same solvent. Consequently, the crystallinity determined is a negative quantity with the SI units kJ/mol or J/g (J/kg is avoided because of its unwieldiness and potential for error). The preference for a negative value with respect to a highly crystalline reference standard recognises the fact that most samples have a lower crystallinity than this reference standard.

Near-infrared (NIR) spectroscopy
Near-infrared (NIR) spectroscopy (*2.2.40*) is another technique used to measure the degree of crystallinity, and has also been proven to be useful in studies of polymorphism. The NIR spectrum of a sample contains both physical and chemical information. Being non-invasive, non-destructive and operable at room temperature, the method is a valuable tool to assess changes in the amorphous and crystalline state.

Infrared absorption spectrophotometry and Raman spectroscopy
Infrared absorption spectrophotometry (*2.2.24*) and Raman spectroscopy (*2.2.48*) are other techniques used to measure the degree of crystallinity, and have also been proven to be useful in studies of polymorphism. The IR spectrum and Raman spectrum of a sample contain both physical and chemical information.

Solid-state NMR
Solid-state nuclear magnetic resonance spectrometry (ss NMR) (*2.2.33*) can be used to provide information about polymorphism and related relative molecular conformations. However, some caution has to be exercised in the interpretation of results, since it is not always simple to distinguish between samples that comprise a mixture of different physical forms (2-state model) and those that comprise crystals having disorder with exchange that is slow on the NMR timescale. Similarly, samples that contain defects arising from different molecular conformations or slightly different packing arrangements (1-state model) may show additional signals in the spectra. Solid-state NMR may be quite sensitive to this, even if lattice parameters are hardly affected and, consequently, little or no change is observed by XRPD. It is evident that the crystallinity of substances for pharmaceutical use can be complex, and both crystalline defects and amorphous material may co-exist.

Optical microscopy
A method to detect whether or not particles are crystalline is to use a polarising microscope (*2.9.37*), where particles show birefringence and extinction positions when the microscope stage is revolved.

V. Characterisation of Crystalline Solids by Microcalorimetry and Solution Calorimetry

(Ph. Eur. method 2.2.61)

For the purpose of this chapter, crystalline material, partially crystalline material and amorphous material are considered as solids.

INTRODUCTION - THE CONCEPT OF CRYSTALLINITY

The perfectly ordered crystal lattice with every molecule in its expected lattice position is an ideal that is seldom, if ever, achieved. The other extreme is the amorphous state, in which a solid contains the maximum possible density of imperfections (defects of various dimensionalities), such that all long-range order is lost while only the short-range order, imposed by its nearest neighbours, remains. Real crystals lie somewhere between these 2 extremes. A crystal's position on a scale bounded by these 2 extremes is termed *crystallinity*.

All real crystals, even in the pure state, possess some lattice imperfections or defects, which increase both the energy (enthalpy under conditions of constant atmospheric pressure) and the disorder (expressed as the entropy) of the crystal lattice. A crystal with a relatively low density of imperfections is said to be highly crystalline and to possess a high crystallinity. By contrast, a particle with a relatively high density of imperfections is said to be partially amorphous and to possess a low crystallinity. In ideal terms, a totally amorphous particle corresponds to zero crystallinity. Amorphous particles may contain somewhat ordered domains that can act as nuclei for crystallisation; such so-called amorphous particles are said to possess a low-level but finite crystallinity.

The ability to detect and to quantify the amount of amorphous material within a highly crystalline substance is of great importance during the development and subsequent manufacture of a pharmaceutical preparation.

In reality, a powder probably contains particles with different degrees of crystallinity, just as it may contain particles with varying sizes and shapes. The lower the crystallinity of a solid, the greater its enthalpy and entropy. The increase in enthalpy is never totally compensated for by the increase in entropy; therefore, the Gibbs free energy, which reflects the balance between them, actually increases. Hence, the lower the crystallinity of a material (powder), and consequently the greater its amorphous character, the greater its apparent intrinsic solubility and dissolution rate, but the lower its thermodynamic stability. Because of the great relevance of these properties, crystallinity is also an important property and requires measurement by a suitable method.

In the following chapter, the crystallinity or the content of amorphous parts of a powder are measured by calorimetric methods such as microcalorimetry or solution calorimetry, although other methods could be used (e.g. see general chapter *2.9.33. Characterisation of crystalline and partially crystalline solids by X-ray powder diffraction (XRPD)*).

Many substances are capable of crystallising in more than one type of crystal lattice, which is known as polymorphism. If water or a solvent is incorporated in the crystal lattice the crystals are termed hydrates or solvates. Because of the different crystal packing, and/or molecular conformation and lattice energy, they usually exhibit different physical properties. For simplicity, calorimetry measurements for degree of crystallinity determination discussed here assume

only one solid crystalline form present in the material of interest. The theory and experimental technique can be easily expanded to polymorphic systems with proper consideration of the enthalpy differences among the polymorphs.

METHOD 1 - MICROCALORIMETRY (DETERMINATION OF AMORPHOUS CONTENT)

Most chemical, physical and biological processes are associated with the exchange of heat. Microcalorimetry is a highly sensitive technique to monitor and quantify both exothermic (heat producing) and endothermic (heat absorbing) changes associated with those processes.
The technique allows the determination of the rate and extent of chemical reactions, changes of phase or changes of structure.

Thermal events producing only a fraction of a microwatt can be observed using microcalorimetry. This means that temperature differences less than 10^{-6} K must be detectable. Microcalorimetry typically uses the heat flow (heat leakage) principle, where the heat produced (or absorbed) in a thermally defined vessel flows away (or into) in an effort to re-establish thermal equilibrium with its surroundings. Exceptional thermal stability with its surrounding has to be achieved either by a heat sink or an electronically regulated surrounding.

Heat energy from an active sample in the reaction vessel is channelled typically through Peltier elements; they act as thermoelectric generators using the Seebeck effect. The heat energy is converted into a voltage signal proportional to the heat flow.

Results are typically presented as a measure of the thermal energy produced per unit of time (Watt) as a function of time.

APPARATUS

Microcalorimeters are typically designed as twin systems with a measuring vessel and a reference vessel. Vessels are typically made of glass or stainless steel. For certain applications specially designed vessels which allow the addition of a gas, a liquid or a solid material may be used.

CALIBRATION

The microcalorimeter is calibrated for heat flow (energy per time unit) using either calibrated external or internal electrical heat sources or a suitable standard reaction.

SENSITIVITY

The sensitivity of the microcalorimetric method can be assessed based on an appropriate standard sample analysed according to the corresponding method in conjunction with the determination of the instrument baseline noise.

PROCEDURE

Weigh in a suitable vessel an appropriate quantity of the substance to be examined. Close the vessel carefully to avoid any evaporation of solvents and place the vessel in the sample holder. If appropriate, allow the vessel to equilibrate at the temperature of the measurement before placing it in the measuring position.

Begin the analysis and record the heat flow, with the time on the abscissa and the heat flow on the ordinate (specify the direction of exothermic or endothermic heat flow).

DETECTION AND QUANTIFICATION OF AMORPHOUS CONTENT IN POWDERS

The amorphous state is metastable with respect to the crystalline state; recrystallisation may therefore occur.
The measurement of the heat of recrystallisation enables the amorphous content to be determined by the area of the recrystallisation peak. By relating the output from the microcalorimeter for a sample to that obtained from an amorphous standard, it is possible to quantify the amorphous content of the sample. The range of amorphous content covered by this method depends on the individual substance to be tested; in favourable cases limits of detection below 1 per cent can be reached.

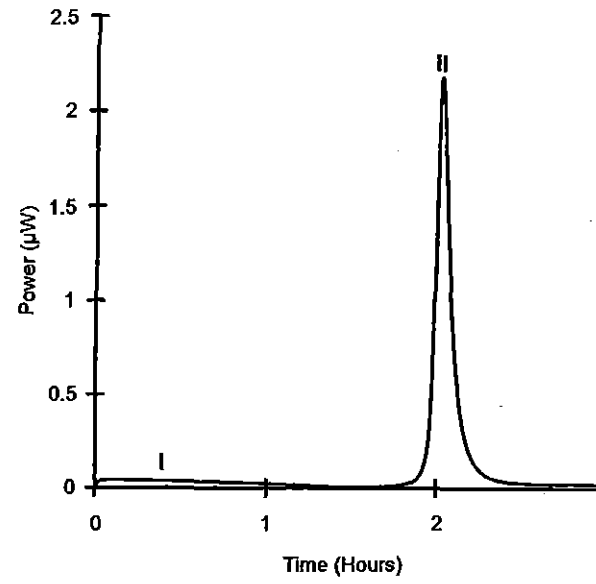


Figure 2.2.61.-1. – *Typical microcalorimetric output of power (in µW) as a function of time (in hours): amorphous collapse peak (I) and crystallisation peak (II) for mainly amorphous lactose at 25 °C and 75 per cent relative humidity*

Recrystallisation can be initiated by subjecting the sample to higher relative humidity or an atmosphere containing organic vapour. The sample is typically placed in an ampoule which also contains a small test-tube containing an aqueous saturated salt solution, an organic solvent, or a solvent mixture.

The heat of recrystallisation is typically measured using a fixed sample mass placed in a glass or steel vessel. The test-tube containing a saturated salt solution or an organic solvent is chosen to be large enough to allow a full saturation of the atmosphere above the sample. The mass of the sample and the nature of the vapour atmosphere above the sample are chosen so that recrystallisation occurs in such a way that a distinct peak is observed, clearly separated from initial thermal events caused by introduction of the sample.

The conditions under which the transition of the amorphous phase to a thermodynamically more stable crystalline state occurs will have a significant impact on the time of recrystallisation. In particular, physical mixtures of purely amorphous and crystalline material will behave differently from a partially crystalline material. These effects should be considered when developing a method.

A typical response for the recrystallisation of a mainly amorphous material is shown in Figure 2.2.61.-1. The first part of the curve represents several concurrent processes taking place simultaneously, such as the absorption of water vapour into the amorphous parts of the powder and the generation of water vapour from the test-tube. After this initial response there is a large exothermic response caused by the recrystallisation of the amorphous material. Also included, but not seen, are the expulsion of excess water from the recrystallised parts and its condensation. Thus, the

area under this exothermic recrystallisation response is proportional to the heat of recrystallisation.

METHOD 2 - SOLUTION CALORIMETRY (DETERMINATION OF CRYSTALLINITY)

Solution calorimetry provides a means of determining enthalpy of solution (i.e. heat of solution under constant atmospheric pressure) of a substance. Enthalpy of solution is defined as the enthalpy of the substance dissolved in the solution to a defined concentration minus the enthalpy of the original substance. The solvent for the dissolution process must be such that the mass of solid dissolves within a time frame that matches the response time of the calorimeter, as discussed below. The enthalpy of solution is proportional to the amount of solid being dissolved. This amount may be defined as 1 mol for molar enthalpy or as 1 g for specific enthalpy. If the substance possesses adequate purity (as determined by the degree of accuracy required) and if its molecular mass is known, the molar enthalpy is preferred, otherwise the specific enthalpy must be used. The enthalpy of solution is weakly dependent on both the temperature, which is usually 25.0 °C, and the final concentration of the dissolved solute.

It is usually preferred to express the crystallinity, P_c, of a substance on a percentage scale. This procedure requires 2 reference standards, namely a highly crystalline sample assuming 100 per cent crystallinity and having a measured enthalpy of solution of ΔH_c^s, and an amorphous sample assuming 0 per cent crystallinity and having a measured enthalpy of solution of ΔH_a^s. From these values and from the measured enthalpy of solution, ΔH_s^s, of the solid under study, the percentage crystallinity of the solid, P_c, may be calculated as follows:

$$P_c(\%) = 100(\Delta H_s^s - \Delta H_a^s)/(\Delta H_c^s - \Delta H_a^s)$$

Clearly, crystallinity expressed on a percentage scale depends on 3 measured values and the enthalpies of solution may be replaced by other corresponding physical quantities that depend on crystallinity. The value of the percentage crystallinity of a sample, however, depends not only on the nature and method of preparation of the 2 reference standards, but also on the choice of the physical quantity that is measured.

The enthalpy of solution is measured either by an isoperibol (constant perimeter, i.e. jacket) solution calorimeter or by an isothermal (constant temperature) solution calorimeter. Typically, at least 3 measurements are made with each sample. The mean of these values is then calculated. The exact requirements will depend upon the equipment capability and degree of accuracy needed.

ISOPERIBOL SOLUTION CALORIMETRY

In the isoperibol solution calorimeter, the heat change during the solution process causes a corresponding change in temperature of the solvent-solute system (i.e. solution). This temperature change is measured by a temperature sensor, which is wired to an electrical circuit that records an electrical signal corresponding to the temperature change. Typically, this temperature change in an electronic form is measured at precisely defined time intervals to produce temperature-time data that are collected, analysed by a computer, and then plotted. A blank run without addition of the solid solute to the solvent normally shows no discernible change in the slope of the temperature-time plot.

For isoperibol solution calorimeters, response is fairly rapid, but corrections must be made for any heat losses to or heat gains from the bath. Therefore, isoperibol solution calorimeters are more advantageous than isothermal solution calorimeters when the solution process is relatively fast.

For all measurements of enthalpy of solution using isoperibol solution calorimeters, the choice of solvent is critical. The nature and mass of the solvent and the mass of sample allow the total heat change, corresponding to total dissolution of the solid, to proceed to completion within 5 min under vigorous stirring at a constant rotational speed within the range of 400-600 r/min.

The effective heat capacity of the calorimeter cell and its contents is determined for every calorimeter run. This determination is accomplished by electrical heating of the contents of the calorimeter cell. The effective heat capacity is determined according to 1 of 2 protocols: either by making 1 determination after ampoule breakage or by making 1 determination before and a 2nd determination after ampoule breakage and then averaging the 2 results. The accuracy and reliability of the electrical heating are established by the accuracy and reliability of the aforementioned chemical calibrations.

ISOTHERMAL SOLUTION CALORIMETRY

In the isothermal (constant temperature) solution calorimeter, the heat change during the solution process is compensated for by an equal but opposite energy change, such that the temperature of the solvent-solute system (i.e. solution) remains essentially constant. This equal but opposite energy change is measured and, when its sign is reversed, provides the enthalpy of solution. For isothermal calorimeters, response is relatively slow, but the compensation process eliminates the effects of heat losses to or heat gains from the bath. Therefore, isothermal solution calorimeters are more advantageous than isoperibol solution calorimeters when the solution process is relatively slow.

SOLUTION CALORIMETER CALIBRATION

To ensure the accuracy of the calorimeter, chemical calibrations must be performed on a regular basis. For an endothermic solution process, the calibration of the calorimeter is checked by measuring the heat absorbed during the dissolution of potassium chloride in distilled water at 298.15 K (25.0 °C). The established enthalpy change in this endothermic process is 235.5 J/g (17.56 kJ/mol). For an exothermic solution process, the calorimeter is checked by measuring the heat evolved during the dissolution of 5 g per litre of tromethamine [tris(hydroxymethyl)aminomethane, THAM] in a 0.1 mol/L aqueous hydrochloric acid solution at 298.15 K (25.0 °C). The established heat for the aforementioned process is −246.0 J/g (−29.80 kJ/mol).

SAMPLE HANDLING

The chemical and physical stability of solids may decrease with decreasing crystallinity. In particular, solids of low crystallinity, especially amorphous solids, tend to sorb water vapour from the atmosphere, leading to crystallisation and a corresponding gain in crystallinity. For these reasons, anhydrous samples whose crystallinity is to be determined must be stored at zero humidity or below critical humidity levels in sealed chambers containing a desiccant, preferably containing an indicator of effectiveness. If crystallinity-humidity studies are to be carried out, the sample is stored in a sealed chamber containing a saturated salt solution to provide a defined relative humidity.

Appendix XVIII

Methods of Sterilisation

Methods of Sterilisation

(Methods of Preparation of Sterile Products, Ph. Eur. general texts 5.1.1)

GENERAL INTRODUCTION

Sterility is the absence of viable micro-organisms, as defined by a sterility assurance level equal to or less than 10^{-6}. Sterility is a critical quality attribute for a wide variety of human and veterinary preparations, including but not restricted to:

- preparations required to be sterile due to their route of administration, such as parenteral, ophthalmic and intramammary preparations, and some inhalation, irrigation and intrauterine preparations;
- preparations applied to severely injured skin, such as semi-solid preparations for cutaneous application.

The achievement of sterility for any one item in a population of items submitted to a sterilisation process can neither be guaranteed nor demonstrated. It is essential to study the effect of the chosen sterilisation procedure on the product (including its final container) to ensure its effectiveness and the integrity of the product, and to validate the procedure before it is applied in practice. Failure to follow meticulously a validated process introduces the risk of a non-sterile and/or deteriorated product.

Sterile products are prepared under appropriate conditions and are packed in suitable containers. It is recommended that the choice of container permits application of the optimum sterilisation process for the product. The container and closure system are required to maintain the sterility of the product throughout its shelf life.

Sterilisation process conditions are chosen to achieve the highest level of sterility assurance compatible with the drug product and, wherever possible, a process in which the product is sterilised in its final container (terminal sterilisation) is chosen. When a fully validated terminal sterilisation method by steam (moist heat), dry heat or ionising sterilisation is used, parametric release (i.e. the release of a batch of sterilised items based on process data rather than submission of a sample of the items to sterility testing) may be carried out, subject to the approval of the competent authority. If terminal sterilisation is not possible, aseptic assembly or filtration through a bacterial retentive filter is used. Wherever possible, an appropriate additional treatment (e.g. heating) of the product in its final container is applied to further ensure the sterility assurance level.

Requirements for the use of biological indicators for validation of sterilisation processes are given in general chapter *5.1.2.*

The present general chapter provides guidance on conditions, validation and control of sterilisation processes. The methods described here apply mainly to the inactivation or removal of bacteria, yeasts and moulds. For biological products of animal or human origin, or in cases where such material has been used in the production process, it is necessary to demonstrate during validation that the process is capable of the removal or inactivation of any relevant viral contamination. Further guidance is provided in general chapter *5.1.7. Viral safety.*

The efficacy of a sterilisation process is dependent on its nature, the processing conditions (e.g. time, temperature, moisture), the pre-sterilisation microbial contamination and the formulation of the product. The inactivation of micro-organisms by physical or chemical means follows an exponential law and hence there is always a non-zero probability that a micro-organism may survive the sterilisation process.

Sterility assurance level (SAL)

In the methods described, reference is made to a sterility assurance level (SAL) where appropriate. The SAL for a given sterilisation process is expressed as the probability of micro-organisms surviving in a product item after exposure to the process. An SAL of 10^{-6}, for example, denotes a probability of not more than 1 non-sterile item in 1×10^6 sterilised items of the final product. The SAL of a process for a given product is established by appropriate validation studies. Microbial contamination may be described by the number, type and resistance of any micro-organisms present. Microbiological monitoring and setting of suitable limits is therefore essential for all components of sterile preparations. Steps designed to reduce microbial contamination, such as filtration prior to sterilisation, will contribute significantly to sterility assurance. The composition of a product can affect the behaviour of micro-organisms present in the product, which in turn can affect the efficacy of the sterilisation process. The water activity (A_w), the pH and the presence of compounds with antimicrobial activity are examples of factors that can influence the resistance of any micro-organisms present. The water activity or the product formulation (including the presence of nutrients) can affect the number of micro-organisms, which in turn can affect the efficacy of the membrane-filtration process.

METHODS AND CONDITIONS OF STERILISATION

Sterilisation may be carried out by one of the methods described hereafter. Modifications to, or combinations of, these methods may be used, provided that the chosen procedure is validated with respect both to its effectiveness and to the integrity of the product including its container. For all sterilisation methods, the critical parameters of the procedure are monitored in order to confirm that any previously determined requirements or conditions are respected throughout the batch during the entire sterilisation process. This applies in all cases, including those where the reference conditions are used. Guidance concerning validation of a steam sterilisation process using the F_0 concept is described in general chapter *5.1.5.* Biological indicators of sterilisation are used to develop and validate sterilisation processes and also to monitor gas sterilisation processes. Guidance on the use of biological indicators is provided in general chapter *5.1.2.*

Precautions shall be taken to prevent contamination of the sterilised articles after the sterilisation phase.

STEAM STERILISATION

Principle

Steam sterilisation is achieved by heat transfer during condensation of water from a saturated vapour phase on the surfaces of the sterilised items. Where items (open or wrapped) are sterilised in direct contact with steam, the hydrating effect of the condensate adds to the sterilising effect. For direct steam exposure, it is essential that the items are fully penetrated by saturated steam, i.e. free of air and other non-condensable gases. Where items are sterilised in closed-containers, the chamber of the steriliser serves as a steam jacket. Condensation on the surface of the containers

still serves as a highly effective mechanism for energy transfer, but has no additional sterilising effect on its own. In closed-container sterilisation, the sterilising effect is determined by the conditions reached within the closed containers, where sterilisation must be achieved in the product itself and in the head-space.

Equipment

Steam sterilisation is performed in autoclaves, i.e. pressure vessels designed to admit or generate steam continuously and to remove condensate from the chamber to maintain the pressure and temperature at controlled levels.

For equipment used to perform direct steam exposure cycles, the supply of saturated steam, free of non-condensable gases, is assured. In autoclaves intended for the sterilisation of closed containers, steam-air mixtures or a superheated water spray can be used to achieve heat transfer. Suitable autoclaves are qualified to achieve homogeneous conditions within the chamber and the load. The principles of operation are appropriate for the items to be sterilised and the loading configuration. The suitability of the equipment for the items to be sterilised and its performance in the chosen cycle is demonstrated in autoclave performance qualification studies. Temperature profiles in the slowest-to-heat items are recorded.

Suitable autoclaves are equipped with temperature and pressure sensors of appropriate sensitivity that are placed in relevant positions to ensure effective process control. Chamber temperature and pressure profiles are recorded for each cycle. There is at least 1 independent thermal probe that controls the load temperature at the slowest-to-heat position or in the slowest-to-heat closed container of the load.

Cooling water sprayed into the chamber at the end of a sterilisation process for closed containers is of sufficient quality not to impact negatively the sterility of the sterilised items.

Sterilisation cycle

Suitable sterilisation cycles are chosen to be compatible with the items to be sterilised and the loading configuration. Where air is displaced from the chamber by gravity, the items to be autoclaved are designed to allow the removal of air and are arranged within the autoclave to prevent the formation of inaccessible air pockets. Where air is removed by vacuum cycles followed by steam pulses, it is assured that the items are not affected by the evacuation process. For pressure-sensitive products in closed containers, saturated steam sterilisation may not be possible. Steam-air mixtures may be applied to the chamber in order to balance pressure conditions inside the closed containers. Steam penetration is assured by choosing suitable cycles to remove air from porous loads or hollow bodies. Steam penetration is verified during cycle development by, for example, the use of physical/chemical indicators, while the biological effectiveness of the cycle is verified by the use of biological indicators (*5.1.2*). Appropriate loading patterns are specified.

Cycle effectiveness

The reference cycle for steam sterilisation is 15 min at 121 °C in saturated steam determined in the coldest position of the chamber. Product- and load-specific cycles, e.g. applying another combination of time and temperature, may be adopted based on cycle development and validation. The minimum temperature acceptable for a steam sterilisation process is 110 °C. The minimum F_0, calculated in the slowest-to-heat position of the load is not less than 8 min. The calculation of sterilisation effectiveness by the F_0 concept is performed according to general chapter *5.1.5*.

Calculated effectiveness from physical parameters (F_{phys}) is correlated with biological effectiveness (F_{bio}). F_{bio} expresses the lethality, in minutes, provided by the process in terms of destruction of the biological indicators used. F_{bio} is calculated by the following equation:

$$F_{bio} = D_{121}(\log_{10} N_0 - \log_{10} N)$$

D_{121} is the *D*-value of the biological indicator at an exposure temperature of 121 °C, N_0 is the number of viable micro-organisms in the biological indicator before exposure, and N is the number of viable micro-organisms in the biological indicator after exposure.

In cycle validation, the relevant positions in the load that are the most difficult to sterilise are determined and adequate biological effectiveness is verified by exposure of biological indicators (*5.1.2*) in these positions or products, whichever is relevant. Protection of spores from the sterilising effect (e.g. by physical occlusion of steam or by the protective properties of the product) are suitably addressed. The F_{bio} determined for the most-difficult-to-sterilise position is used to define the parameters necessary to achieve reliably the required SAL equal to or less than 10^{-6} for the chosen cycle.

Routine control

Autoclave cycles are monitored by physical determination of chamber pressure and temperature profiles, at a minimum, in the coldest position of the chamber. For each cycle, pressure, time and temperature are recorded and, if possible, F_0 is calculated and recorded.

DRY HEAT STERILISATION

Principle

Dry heat sterilisation is a terminal sterilisation method based on the transfer of heat to the articles to be sterilised. Heat may be transferred by means of convection, radiation or direct transfer.

Equipment

Dry heat sterilisation is carried out in an oven with forced air circulation or using other equipment specifically designed for this purpose, e.g. a tunnel.

Sterilisation cycle

The steriliser is loaded in such a way that the specified or required temperature is achieved throughout the load. Knowledge of the temperature within the steriliser during the sterilisation cycle is obtained by means of temperature-sensing elements suitably placed in or on representative items situated in the coolest part (as previously established) of the loaded steriliser. The time and temperature throughout each cycle is suitably recorded.

Cycle effectiveness

The reference conditions for this method of sterilisation are a minimum of 160 °C for at least 2 h. Other combinations of time and temperature may be used if it has been satisfactorily demonstrated that the process chosen delivers an adequate and reproducible level of lethality when operated within the established tolerances. The procedures and precautions employed are such as to achieve an SAL equal to or less than 10^{-6}. Dry heat sterilisation processes are validated using a combination of temperature mapping and biological indicator studies (*5.1.2*).

Dry heat at temperatures greater than 220 °C, for a validated time, is frequently used for depyrogenation of glassware. In this case, demonstration of a 3 $\log_{10}$ reduction in heat-

resistant endotoxin can be used as validation criteria and biological indicators will not be needed.

Routine control
Dry heat sterilisation cycles are monitored by determination of temperature profiles, at a minimum, in the coldest position of the chamber. Time and temperature are recorded for each cycle.

IONISING RADIATION STERILISATION

Principle
Sterilisation by irradiation is achieved by exposure of the product to ionising radiation in the form of either gamma rays from a suitable isotopic source (such as cobalt 60), a beam of electrons energised by a suitable electron accelerator, or X-rays resulting from bombarding a suitable target with energised electrons. Ionising radiation may be used for the terminal sterilisation of finished dosage forms, the microbial inactivation of tissues and cells, or the sterilisation of materials or containers to be employed in aseptic processing. Low-energy electrons may be used for the surface sterilisation of materials upon entry to isolators used in the preparation of sterile products.

Cycle effectiveness
For this method of sterilisation, the reference absorbed dose is 25 kGy. Other doses may be used if, during validation of the sterilising dose, it has been satisfactorily demonstrated that the dose chosen delivers an adequate and reproducible level of lethality when the process is operated routinely within the established tolerances. The procedures and precautions employed are such as to achieve an SAL equal to or less than 10^{-6}. Biological indicators may be required for the development and validation of the sterilisation of tissues and cell products. They may also be required for products with a potential to prevent spore inactivation.

Routine control
During the sterilisation process, the sterilisation dose delivered is monitored using a dosimetry system, measurements from which are traceable to national standards.

GAS STERILISATION (VAPOR PHASE STERILISATION)

Principle
Gas sterilisation of surfaces may be used for the sterilisation of primary packaging materials, equipment and some pharmaceuticals.

It is essential that penetration by gas and moisture into the material to be sterilised is ensured, and that it is followed by a process whereby the gas is eliminated under conditions that have been previously established as sufficient to ensure that any residues of gas or related transformation by-products are below concentrations that could give rise to toxic effects during product use.

Sterilising agents
There are 2 main categories of gaseous sterilising agents as distinguished by their antimicrobial action: alkylating agents and oxidising agents.

Alkylating agents Alkylating agents are highly reactive compounds and interact with many components, such as amino, sulfhydryl and hydroxyl groups in proteins and purine bases in nucleic acids.

Ethylene oxide is an alkylating agent that is associated with cytotoxic, carcinogenic and mutagenic effects.

Oxidising agents Oxidising agents are highly reactive, toxic compounds. Such compounds currently used as sterilising agents include hydrogen peroxide and peracetic acid.

Development and validation of sterilisation processes
Gas sterilisation is performed by exposure of the product to the sterilising agent in a leak-proof chamber under specified conditions.

A typical gas sterilisation process consists of 3 phases: (pre) conditioning, sterilisation and aeration. The parameters necessary for these phases to produce the required SAL are established during process development. A combination of physical and biological methods is used to determine the optimum sterilisation conditions. The cycle shall not compromise the functionality of either product or the container.

Sterilisation cycle
Specialised equipment may be required for the monitoring of temperature, humidity and gas concentration during both validation and routine operation.

Cycle effectiveness
Validation of microbiological performance shall confirm the effectiveness of the defined process for the product/load combination in the steriliser. The lethality of the cycle may be determined by using an appropriate approach: after time-graded exposures, the rate of inactivation (*D*-value) of the test organisms can be established by construction of a survivor curve or by using a fraction-negative method.

Biological indicators shall be shown to be, at a minimum, as resistant to the sterilising agent as the microbiological contaminants of the product to be sterilised. They shall be placed within the product at locations where sterilising conditions are most difficult to achieve.

The effectiveness of the process is dependent on a number of parameters, including gas concentration, temperature, humidity, exposure time, load configuration and characteristics of the product and its packaging materials. The effect on the process effectiveness of any change in one or more of these parameters shall be investigated.

Routine control
The relevant cycle process parameters (including the results of the biological indicator test) are recorded.

MEMBRANE FILTRATION

Principle
Membrane filtration is used for reduction of viable and non-viable particles in gases and fluid products that are not amenable to sterilisation by heat or irradiation. In contrast to other sterilisation methods, the principle of membrane filtration is not inactivation but removal of microorganisms from the product. Removal is achieved by a combination of sieving and surface interaction.

Equipment
Membrane filters are available as flat stock (discs) in appropriate holders or as cartridges. Pore size ratings are based on the correlation between microbial retention and diffusion characteristics or bubble-point measurement. Many factors contribute to the effectiveness of the filtration process, e.g. shape, pore size, structure, surface properties, the structure and arrangement of the filter unit, interaction of the filter matrix with the product, applied pressure, flow and duration of the process. Filter characteristics have to be determined in a product-specific validation. Suitable integrity test procedures (e.g. diffusive flow measurement, bubble-point determination or water-intrusion testing) are employed, as recommended by filter manufacturers. Chemical and physical compatibility of the membranes with the product to

be filtered and the conditions of the filtration process are demonstrated in development studies. The filter size is suitable for the volume of the product to be filtered and the bioburden.

For sterilisation of process gases, an appropriate frequency for physical integrity testing is established.

Filtration effectiveness

Microbial challenge tests with a suitable model system shall demonstrate the effectiveness of the filtration process. Where testing with the product is not possible (e.g. due to the antimicrobial properties of the product), a fluid that is representative of the product shall be used, or the test conditions are modified.

It is recommended that the filtration process is carried out as close as possible to the filling point.

Sterilisation of membrane filters

Membrane filters may be sterilised off-line or in-line.
If sterilisation is off-line, steam penetration is verified and the filter is suitably protected against contamination.
The sterilised filter is aseptically assembled in the production line by means of a validated procedure. For in-line sterilisation, steam penetration throughout the filtration equipment is assured and the pressure difference across the membrane is controlled to prevent damage to the membrane itself.

Filtration process

Sterilisation by membrane filtration is performed by passage of the product through a microporous membrane with a nominal pore size not greater than 0.22 µm.

The pre-sterilisation microbial contamination is determined for each batch of product and process parameters are applied as established and validated in the development of the filtration process.

Where multiple bioburden-reduction filters are used to increase the efficacy of the filtration process, the filter closest to the filling point in the final container is characterised as the sterilising filter.

The sterility and integrity of the equipment downstream from the point of filtration, the qualified environmental conditions and the validated aseptic procedures applied in the handling of the filtered product all contribute to preventing recontamination of the product. This is addressed in the section on aseptic assembly.

Routine control

Filtration processes are monitored by physical and microbiological determination of parameters established during validation studies. These parameters include the following: pre-sterilisation microbial contamination, pre-filtration integrity test results, duration of filtration, volume filtered, differential pressure and post-filtration integrity test results.

ASEPTIC ASSEMBLY

Principle

The objective of aseptic assembly is to maintain the sterility of a product that is assembled from components, each of which has been sterilised by one of the above methods. This is achieved by using conditions and facilities designed to prevent microbial contamination.

Aseptic processing may include aseptic filling of products into container/closure systems, freeze-drying under aseptic conditions, aseptic blending of formulations followed by aseptic filling, and aseptic packaging.

Development and validation of aseptic assembly

In order to maintain the sterility of the components and the product during assembly, careful attention needs to be given to the following:

- environment;
- personnel;
- critical surfaces;
- container/closure sterilisation and transfer procedures;
- the maximum holding period of the product before filling into the final container.

Process validation includes appropriate checks on all of the above and also regular checks on the process, which are carried out by means of process simulation tests using microbial growth media that are then incubated and examined for microbial contamination (media fill tests).
In addition, a suitable sample of each batch of any product that is aseptically processed is tested for sterility (*2.6.1*).

Biological Indicators of Sterilisation

(Biological Indicators and Related Microbial Preparations used in the Manufacture of Sterile Products, Ph. Eur. general texts 5.1.2)

1 INTRODUCTION

The use of biological indicators in this general chapter is intended to cover the sterilisation of finished products and relevant related sterilisation processes i.e. sterilisation processes for items coming into direct contact with the final sterilised product. Other uses of biological indicators to validate the sterilisation of other non-terminal units is outside the scope of this general chapter.

Biological indicators are test systems containing viable micro-organisms (usually spores of bacteria) that provide a defined challenge to verify the required effectiveness of a specified sterilisation process.

Biological indicators are intended for the development and validation of the sterilisation processes and not for routine monitoring unless otherwise stated in this general chapter.

The validity of the sterilisation process and the validity of the biological indicators can be assured by the use of reduced sterilisation process conditions, whereby a small proportion of the micro-organisms within the biological indicator will be shown to survive. However, when the validated sterilisation process is used, there will be no surviving viable micro-organisms (see section 3-1-2).

Bacterial spores are resistant forms of life, they can be produced and standardised, and may be stored for long periods of time under appropriate conditions.

Commercially available biological indicators typically contain a standardised population of spores of a suitable bacterium. In cases where no suitable commercial biological indicators are available to characterise the sterilising effect in the product or at a position difficult to penetrate by the sterilant, custom-made biological indicators may be used. Such biological indicators can be prepared by inoculating a standardised spore suspension onto or into the item or product to be sterilised, such action may change the characteristics of the biological indicator.

A suspension of vegetative bacterial cells is used to validate the bacterial retention capability of sterilising grade filters when applied as a sterilisation step in an aseptic production process.

2 BIOLOGICAL INDICATORS FOR STERILISATION PROCESSES

In addition to the physical sterilisation parameters, the effectiveness of a sterilisation process as described in general chapter *5.1.1* is dependent on a large number of variables,

which may include, but is not necessarily restricted to, the number and resistance of contaminating micro-organisms, penetration of the sterilant, time, temperature, concentration, pH, moisture content, and the chemical composition of the product or item being sterilised.

To validate a sterilisation process, physical conditions are chosen that are expected to sterilise the items in the load to achieve a sterility assurance level (SAL) equal to or less than 10^{-6} as described in general chapter *5.1.1*. In a physical validation process it is demonstrated that these conditions are delivered homogeneously to all parts and positions of the load. It is the aim of biological validation to demonstrate the correlation between the predicted effect of the physical conditions applied during the process and the observed biological effect on biological indicators. Using process parameters that have been demonstrated to deliver the required biological effect will ensure sterility of the resulting product in routine processing.

The selection of the type of biological indicator used will depend on:

— the nature of the sterilising agent (e.g. heat, gas or radiation);
— the expected effectiveness of the treatment (e.g. the F_{phys} calculated from the process parameters);
— the process conditions (e.g. temperature, time, relative humidity, gas concentration, radiation dose);
— the characteristics of the pharmaceutical product or item (e.g. product in final container, packaging material, utensils such as tubes or pumps) to be sterilised.

In the development of a sterilisation process, the load and the product should be assessed to determine the most difficult position to sterilise (e.g. cold spots, vial-stopper interface, difficult to penetrate areas). When choosing the optimum biological challenge to a sterilisation process, the conditions in the most difficult position to sterilise in the load and the product should be simulated as closely as possible.

Spores inoculated into a product or onto surfaces are known to react differently to sterilising conditions as compared to biological indicator units. In these cases, commercially available biological indicator units may not be suitable to test sterilisation effectiveness and an inoculated test product/item prepared from a well-characterised spore suspension may be a better model to evaluate the effectiveness of the sterilisation cycle.

2-1 DESCRIPTION OF BIOLOGICAL INDICATORS FOR STERILISATION PROCESSES

Depending on the process to be characterised, a suitable biological challenge may consist of biological indicators presented as test micro-organism suspensions, inoculated carriers, or self-contained biological indicators. The user must establish a high level of confidence in the manufacturer's compliance to quality standards for the biological indicator (e.g. by means of auditing) in order to rely on the characteristics stated by the manufacturer (see section 2-2). Alternatively, the labelled characteristics of biological indicators shall be verified by the user or by an independent, contract laboratory that is formally approved by the user. For custom-made biological indicators (see section 2-1-4), the characteristics shall be verified by the user or by a contract laboratory.

2-1-1 Inoculated carriers

Inoculated carriers consist of a defined population of bacterial spores inoculated into or onto a suitable carrier, and in most cases, in a protective envelope. The type of carrier (and the envelope if used) may influence the resistance of the bacterial spores and must be compatible with the chosen sterilisation process (e.g. strips of filter paper in glassine envelopes are frequently used for steam and ethylene oxide, while metal discs packaged in non-woven fibre envelopes are used for hydrogen peroxide vapour). After exposure to the sterilisation process, the carrier is aseptically handled according to the manufacturer's instructions, transferred to a suitable culture medium and incubated for a sufficient period of time at the appropriate temperature.

2-1-2 Self-contained biological indicators

A self-contained biological indicator may be, for example:

— a system consisting of an inoculated carrier and a container (e.g. ampoule) with a nutrient medium suitable for the test micro-organism used; the system is designed in such a way that the sterilising agent comes into contact with the inoculated carrier (e.g. through a tortuous path or a filter) while the growth-promoting properties of the nutrient medium are not adversely affected by the sterilisation process. After sterilisation, the carrier is brought into contact with the nutrient medium by simple manipulation. This type of biological indicator system may be used to characterise moist heat sterilisation processes including assurance of the penetration of steam into the system;
— a container (e.g. ampoule) of a population of the test micro-organism in an appropriate nutrient medium. After sterilisation, the container is incubated without further manipulation. This type of biological indicator is sensitive only to an exposure time and temperature and may be used primarily to monitor sterilisation of aqueous fluids. In order to facilitate detection of growth, the medium may contain an indicator (e.g. a pH indicator).

Self-contained biological indicators might not be suitable for the validation of certain sterilisation processes.

2-1-3 Characterised spore suspensions

Characterised spore suspensions consist of a defined population of bacterial spores, prepared from a clearly characterised and suitably maintained strain of a spore-forming bacterial species (e.g. of the genera *Bacillus* or *Clostridium*) in a stable suspension.

2-1-4 Custom-made biological indicators

Custom-made biological indicators are test items (e.g. rubber stoppers), or products, inoculated with a suitable test micro-organism, usually from a characterised spore suspension but also from spore suspensions prepared from isolates from environmental monitoring or other microbiological testing using a well-defined procedure designed to give satisfactory sporulation. The *D*-value (time for 90 per cent reduction of micro-organisms under the stated conditions) and, when appropriate, the *z*-value (see section 3-1-1) of the spore suspension must be determined. Also the *D*-value and *z*-value (if appropriate) of the spores of the inoculated test items/ products must be determined as this may be different from the spores in suspension.

After exposure to the sterilisation cycle, the custom-made biological indicator is enumerated or tested for the presence/absence of surviving test micro-organisms using a validated, appropriate microbiological technique.

2-2 QUALITY REQUIREMENTS FOR BIOLOGICAL INDICATORS

The following are required to be known by the user per delivery of each batch:

— genus and species of the micro-organism (including the type culture collection number where applicable);
— unique reference (e.g. batch number);

— logarithm of the viable spore count expressed to 1 decimal place in scientific notation;
— recovery method used;
— type of carrier;
— type of packaging (e.g. envelope);
— composition of the recovery medium, if needed (e.g. in case of self-contained biological indicators);
— type of indicator (e.g. pH indicator) for growth, if relevant;
— type of sterilisation process(es) and the conditions for which the biological indicator has been characterised;
— resistance (*D*-value) per batch of finished biological indicator against the specified sterilisation processes throughout the labelled shelf-life; the *D*-value should be stated in applicable units (e.g. time or dose) and expressed to 1 decimal place, together with a 95 per cent confidence interval if feasible;
— method (inactivation kinetics or fraction negative method) used to determine the resistance (*D*-value); parameters to verify e.g. exposure conditions, number of replicates tested, medium and incubation conditions used for recovery after exposure, etc.;
— the *z*-value (where relevant) for the biological indicator stated in temperature units expressed to 1 decimal place in scientific notation, including the range of temperatures used to determine the *z*-value;
— the storage conditions and the expiry date.

2-2-1 User requirement specification (URS)

The particular sterilisation process (moist heat, dry heat, gas, or ionising radiation) is considered as the basis for the choice of the biological indicator. This choice includes the selection of the test micro-organism, the type of biological indicator (inoculated carrier, self-contained, or custom-made), the *D*-value, and the initial spore count. Moreover, the resistance of the test strain is suitable for the particular sterilisation method and is great compared to the resistance of micro-organisms potentially contaminating the product.

2-2-2 Quality control

Quality control for biological indicators consists of testing for purity, identity and estimation of the number of viable cells. The biological indicator should be compliant with the URS. Users employing biological indicators outside of the manufacturer's labelled recommendations should thoroughly characterise the biological indicators for the particular sterilisation process.

Purity

Examination of the micro-organisms on a suitable culture medium incubated under appropriate conditions shall not show any evidence of contamination.

Identification

Colony morphology and homogeneity of the population are verified, as appropriate.

Viable count

The viable count is performed according to the manufacturer's instructions or by any other validated method.

2-2-3 Suitability for purpose

The user shall ensure that the biological indicator is inactivated to the expected survival rate by the particular range of sterilisation conditions used.

3 BIOLOGICAL INDICATORS FOR HEAT STERILISATION

3-1 PARAMETERS OF BIOLOGICAL INDICATORS FOR HEAT STERILISATION

3-1-1 *z*-Value

Sterilisation processes can be operated at temperatures lower than the standard 121 °C (for longer exposure times) or at higher temperatures (for shorter exposure times). The *z*-value (the temperature difference that leads to a 10-fold change in the *D*-value of the biological indicator) is used to compare the efficacy of 2 cycles operated at different temperatures. For a *z*-value determination, the *D*-value must be determined at 3 or more temperatures. The intended process temperature should be within the range of the 3 temperatures. The $\log_{10}$ of the *D*-value is plotted against the temperature in degrees Celsius. The *z*-value is equal to the negative reciprocal of the slope of the best-fit linear curve as determined by $\log_{10}$-linear regression analysis.

3-1-2 Establishment of validation cycle

The characteristics of the sterilisation process (e.g. time-temperature combination, level of sterility assurance or F_0 required) are the basis for the choice of the biological indicator (type of biological indicator, test micro-organism, and initial viable count).

Inactivation of micro-organisms under sterilising conditions can be described by lethality kinetics and statistical probabilities. For a number of biological indicator units with an initial population of N_0 micro-organisms per unit and a given *D*-value, the exposure time in minutes where all units are expected to carry survivors (average of 100 surviving spores per unit) is calculated by equation (1).

$$t_s = D \times (\log_{10} N_0 - 2) \qquad (1)$$

t_s = survival time

The exposure time in minutes where all units are expected to be inactivated (average of 10^{-4} surviving spores per unit) is calculated by equation (2).

$$t_k = D \times (\log_{10} N_0 + 4) \qquad (2)$$

t_k = kill time

The objective of a validation study is to demonstrate that the sterilisation effectiveness anticipated from the physical process parameters is equivalent to the biological sterilisation effectiveness. As part of that objective, the exposure time during validation t_{vb} shall not exceed t_k. If a too high t_{vl} is chosen, even a relatively large increase in the *D*-value would still result in biological indicator units with no surviving micro-organisms. In this case, the suboptimal sterilising conditions would not be detected. It is considered reasonable to choose a t_{vl} not higher than required to expect 1 in 1000 biological indicator units having surviving micro-organisms. However, too short a t_{vl} shall not be chosen. If a t_{vl} is chosen such that 50 per cent of the biological indicator units have surviving micro-organisms, changes in the sterilising conditions (e.g. time, temperature) could still result in 100 per cent of the biological indicator units having surviving micro-organisms, and the test would be meaningless. For these reasons, a t_{vl} is chosen such that a theoretical survival rate between 10^{-1} and 10^{-3} is expected, thus:

$$D \times (\log_{10} N_0 + 1) \leq t_{el} \leq D \times (\log_{10} N_0 + 3) \qquad (3)$$

In general, biological indicators are subjected to the intended sterilisation process. However, for highly effective sterilisation processes, the calculated effectiveness of the cycle may be such that the t_k is exceeded by a wide margin. In such instances, biological validation is carried out with reduced sterilisation cycles. Such reduced cycles may be shorter in time (e.g. half cycle) or be performed at a lower temperature. In the latter case the z-value for the test micro-organism under the actual sterilising conditions shall be known.
A reduced cycle is chosen such that the temperature is not more than 1 z-value below the reference sterilisation process temperature. Biological indicators of an appropriate resistance for that cycle show an expected micro-organism survival rate within a window between the lower t_{el} and the t_k (see equation (3)). A decision not to perform this test must be justified.

Depending on the D-value of the test micro-organism and the t_{el} chosen, biological indicators having surviving micro-organisms can be expected with a low frequency (not more than 1 in 10). If it can be demonstrated that the frequency of biological indicators having surviving micro-organisms is within the expected range and is not due to inappropriate sterilising conditions, the process can be accepted.

Following a full sterilisation cycle, all biological indicators in a validation study must be inactivated, thereby proving at least a 10^6 reduction in micro-organisms. It can then be concluded, from the resistance of the spore preparation used, that the process has delivered sufficient lethality to achieve the required sterility assurance level.

3-2 BIOLOGICAL INDICATORS FOR MOIST HEAT STERILISATION

3-2-1 Test micro-organisms

Geobacillus stearothermophilus is the most widely accepted biological indicator micro-organism for moist heat sterilisation processes. Reported $D_{121°C}$-values for its spores are in the range of 1.5 min to about 4.5 min, depending on sporulation conditions, the carrier material on which the spores are inoculated, the primary package surrounding the inoculated carrier, and the environment during sterilisation. Strains ATCC 7953, NCTC 10007, CIP 52.81, NCIMB 8157 and ATCC 12980 (equivalent to NRRL B-4419) have been found to be suitable. Other strains may be used, provided equivalent performance has been demonstrated. It is recognised that a 10^5 or 10^6 population of *Geobacillus stearothermophilus* may not be suitable for sterilisation processes delivering an F_0 between 8 and 15, therefore a lower spore number (i.e. 10^3 or 10^4) or a different test micro-organism may be used. Where a test micro-organism other than *Geobacillus stearothermophilus* (e.g. *Bacillus subtilis* ATCC 35021) is used, the resistance of the test micro-organism is evaluated to ensure its suitability for the process.

3-3 BIOLOGICAL INDICATORS FOR DRY HEAT STERILISATION

The reference conditions are stated in general chapter *5.1.1.* Heat transfer is less effective with dry heat than with steam, and temperature distribution in dry heat sterilisers is less homogeneous compared to steam sterilisers.

For example, biological indicators available for dry heat sterilisation have $D_{160°C}$-values within a range of 1 to 5 min. When exposed to the reference cycle of 2 h at 160 °C, a biological indicator with a $D_{160°C}$-value of 2.5 min would be inactivated by 48 $\log_{10}$ scales. For dry-heat sterilisation processes, z-values of about 20 °C are typically assumed in calculations of equivalence of cycle effectiveness (F_H-calculations). F_H is the equivalent time in minutes at a temperature of 160 °C delivered by the sterilisation process to the product in its final container. For a biological indicator with a $D_{160°C}$-value of 5 min, the $D_{150°C}$-value would be about 16 min, and inactivation in the reference cycle would be 7.5 $\log_{10}$ scales. The use of a sterilisation process at a temperature reduced from the target temperature by 10 °C would give an expected 1 in 30 biological indicator units having surviving micro-organisms.

3-3-1 Test micro-organisms

Spores of *Bacillus atrophaeus* (e.g. ATCC 9372, NCIMB 8058, NRRL B-4418, or CIP 77.18) have been found to be suitable for use as biological indicators for dry heat sterilisation processes performed at temperatures between 160 °C and 180 °C. Where a test micro-organism other than *Bacillus atrophaeus* is used, to ensure its suitability, the resistance of the test micro-organism for the sterilisation process is evaluated as described in section 3-1-2

4 BIOLOGICAL INDICATORS FOR GAS STERILISATION

The use of biological indicators is necessary for the development, validation and monitoring of all gaseous sterilisation processes. Gas sterilisation is a multi-factorial process: gas concentration, humidity, temperature, time, surface characteristics interact in a complex manner.
A number of gas sterilisation processes are currently used, including ethylene oxide, hydrogen peroxide and peracetic acid or combinations of the latter.

Gas surface disinfection is widely used for medical devices, isolators, chambers, etc. Use for such purposes is outside the scope of the European Pharmacopoeia but the use of biological indicators as described in this general chapter may assist in the validation of such disinfection processes.

4-1 TEST MICRO-ORGANISMS

4-1-1 Ethylene oxide sterilisation

The use of spores of *Bacillus atrophaeus* (e.g. ATCC 9372, NCIMB 8058, NRRL B-4418, or CIP 77.18), or other strains of micro-organism having demonstrated equivalent performance, is recommended for ethylene oxide sterilisation. The number of viable spores is greater than or equal to 10^6 per carrier. Test micro-organisms shall have D-values relevant to the process to be validated. These biological indicators are used routinely during each sterilisation cycle thus allowing the effectiveness of the process to be checked.

4-1-2 Other processes

It is the responsibility of the user to define the sterilisation cycle and the suitability of any biological indicator used. *Geobacillus stearothermophilus* has been found suitable for vaporised hydrogen peroxide processes.

5 BIOLOGICAL INDICATORS FOR IONISING RADIATION STERILISATION

Unless otherwise indicated, biological indicators are not generally considered necessary for validation of the sterilising dose for radiation sterilisation. The use of biological indicators may however be required for the development and validation of ionising radiation sterilisation e.g. of tissues, cell preparations or other specific cases (e.g. products with a potential for spore protection).

5-1 TEST MICRO-ORGANISMS

Spores of *Bacillus pumilus* (e.g. ATCC 27142, NCTC 10327, NCIMB 10692 or CIP 77.25) or other strains of micro-

organisms having demonstrated equivalent or better performance are recommended.

6 MICROBIAL PREPARATIONS FOR STERILISATION GRADE FILTRATION

As stated in general chapter *5.1.1*, certain products that cannot be sterilised in their final container may be sterilised by a filtration process. In contrast to the biological indicators discussed in the previous sections, which assess kill-based sterilisation, the biological challenge assesses the retention of micro-organisms by the filters.

To validate the sterilisation process, it must be demonstrated that the filtration process (usually in a scaled-down model) is capable of completely retaining a microbial challenge of at least 10^7 CFU per square centimetre of effective filter surface using a suitable test micro-organism. This test should mimic the actual filtration process as closely as possible. Where feasible, the test is carried out in the product using the specified filtration conditions. If this is not possible, e.g. due to the antimicrobial properties of the product, a medium as similar as possible to the product must be used in the test.

6-1 TEST MICRO-ORGANISMS

For processes using a filtration system with a nominal pore size not greater than 0.22 µm, a suspension of *Brevundimonas diminuta* (ATCC 19146, NCIMB 11091 or CIP 103020) is recommended. The *Brevundimonas diminuta* suspension must be prepared in order to achieve predominantly single cells of the smallest possible size. Other micro-organisms, for example natural flora isolated from the product or process in question, may be used if presenting a stronger challenge to the sterile filtration system than *Brevundimonas diminuta*. For filtration systems with a nominal pore size of 0.1 µm or less, a suspension of *Acholeplasma laidlawii* (ATCC 23206) may be used.

Methods of Sterilisation

(Application of the F Concepts to Heat Sterilisation Processes, Ph. Eur. general texts 5.1.5)

The following chapter is published for information.

INTRODUCTION

Heat sterilisation can be differentiated into 2 types: moist heat sterilisation using saturated steam or water heated to the sterilisation temperature; and dry heat sterilisation using hot air with a moisture content so low as to have an insignificant biological activity.

DEFINITIONS

The *D*-value (or decimal reduction value) is the time in minutes required at a defined temperature to reduce the number of viable test micro-organisms by 90 per cent. It is only of significance under precisely defined experimental conditions.

The *z*-value is the change in temperature in degrees Celsius required to alter the *D*-value by a factor of 10 (the *z*-value relates the resistance of a micro-organism to changes in temperature). The *z*-value is calculated using the following equation:

$$z = \frac{T_2 - T_1}{log_{10}D_1 - log_{10}D_2}$$

D_1 = *D*-value of the micro-organism at temperature T_1;
D_2 = *D*-value of the micro-organism at temperature T_2;
T = temperature.

The *F*-value of a heat sterilisation process (F_0 for moist heat sterilisation or F_H for dry heat sterilisation) is the lethality expressed in terms of the equivalent time in minutes at the reference temperature delivered by the process to the sterilisation load, with reference to micro-organisms possessing the relevant theoretical *z*-value in Table 5.1.5-1.

The total *F* of a process takes into account the heating and cooling phases of a cycle and can be calculated by integration of lethal rates with respect to time at discrete temperature intervals above the minimum temperature specified in Table 5.1.5-1.

The following mathematical relationships apply:

$$F_0 = D_{121}(\log_{10} N_0 - \log_{10} N)$$

$$F_H = D_{160}(\log_{10} N_0 - \log_{10} N)$$

D_{121} = *D*-value of the reference spores (*5.1.2*) at 121 °C;
D_{160} = *D*-value of the reference spores (*5.1.2*) at 160 °C;
N_0 = initial number of viable micro-organisms;
N = final number of viable micro-organisms.

Table 5.1.5.-1 – *Parameters for moist heat and dry heat sterilisation*

Sterilisation	*F*	Theoretical *z*-value (°C)	Reference temperature (°C)	Minimum temperature (°C)
Moist heat	F_0	10	121	110
Dry heat	F_H	20	160	140

For both dry and moist heat sterilisation cycles, the relevant *F*-value is used to demonstrate that the required sterility assurance level of equal to or less than 10^{-6} is consistently achieved.

Appendix XIX

A. Containers Introduction

(Ph. Eur. general texts 3.2)

This Appendix provides requirements, guidance and information on containers for pharmaceutical use. Additional guidance is provided in a number of British Standards. Attention is drawn in particular to British Standards 1679-5: 1973, 1679-6: 1994, 1679-7: 1968 and 1679-8: 1992. The expression 'tamper-evident container' means a closed container fitted with a device that reveals irreversibly whether the container has been opened, whereas, the expression 'tamper-proof container' means a closed container in which access to the contents is prevented under normal conditions of use. The two terms are considered to be synonymous by the European Pharmacopoeia Commission.

A container for pharmaceutical use is an article that contains or is intended to contain a product and is, or may be, in direct contact with it. The closure is a part of the container.

The container (see General Notices section 1.3) is so designed that the contents may be removed in a manner appropriate to the intended use of the preparation.
It provides a varying degree of protection depending on the nature of the product and the hazards of the environment, and minimises the loss of constituents. The container does not interact physically or chemically with the contents in a way that alters their quality beyond the limits tolerated by official requirements.

Single-dose container A single-dose container holds a quantity of the preparation intended for total or partial use on 1 occasion only.

Multidose container A multidose container holds a quantity of the preparation suitable for 2 or more doses.

Well-closed container A well-closed container protects the contents from contamination with extraneous solids and liquids and from loss of contents under ordinary conditions of handling, storage and transport.

Airtight container An airtight container is impermeable to solids, liquids and gases under ordinary conditions of handling, storage and transport. If the container is intended to be opened on more than 1 occasion, it must be so designed that it remains airtight after re-closure.

Sealed container A sealed container is a container closed by fusion of the material of the container.

Tamper-evident container A tamper-evident container is a closed container fitted with a device that reveals irreversibly whether the container has been opened.

Child-proof container A container that is fitted with a closure that prevents opening by children.

B. Glass Containers for Pharmaceutical Use

(Ph. Eur. method 3.2.1)

Glass containers for pharmaceutical use are glass articles intended to come into direct contact with pharmaceutical preparations.

Colourless glass Is highly transparent in the visible spectrum.

Coloured glass Is obtained by the addition of small amounts of metal oxides, chosen according to the desired spectral absorbance.

Neutral glass Is a borosilicate glass containing significant amounts of boric oxide, aluminium oxide, alkali metal oxides and/or alkaline earth oxides in the glass network. Due to its composition, neutral glass has a high hydrolytic resistance and a high thermal shock resistance.

Soda-lime-silica glass Is a silica glass containing alkali metal oxides, mainly sodium oxide, and alkaline earth oxides, mainly calcium oxide, in the glass network. Due to its composition, soda-lime-silica glass has only a moderate hydrolytic resistance.

The hydrolytic stability of glass containers for pharmaceutical use is expressed by the resistance to the release of soluble mineral substances into water under the prescribed conditions of contact between the inner surface of the container or glass grains and water. The hydrolytic resistance is evaluated by titrating released alkali reacting ions.
According to their hydrolytic resistance, glass containers are classified as follows:

— type I glass containers: neutral glass, with a high hydrolytic resistance due to the chemical composition of the glass itself;
— type II glass containers: usually of soda-lime-silica glass with a high hydrolytic resistance resulting from suitable treatment of the inner surface;
— type III glass containers: usually of soda-lime-silica glass with only moderate hydrolytic resistance.

The following italicised statements constitute general recommendations concerning the type of glass container that may be used for different types of pharmaceutical preparations. The manufacturer of a pharmaceutical product is responsible for ensuring the suitability of the chosen container.

Type I glass containers are suitable for most preparations whether or not for parenteral administration.

Type II glass containers are suitable for most acidic and neutral, aqueous preparations whether or not for parenteral administration.

Type III glass containers are in general suitable for non-aqueous preparations for parenteral administration, for powders for parenteral administration (except for freeze-dried preparations) and for preparations not for parenteral administration.

Glass containers with a hydrolytic resistance higher than that recommended above for a particular type of preparation may generally also be used.

The container chosen for a given preparation shall be such that the glass material does not release substances in quantities sufficient to affect the stability of the preparation or to present a risk of toxicity. In justified cases, further detailed information may be necessary to assess the impact on chronic use and for vulnerable patient groups.

Preparations for parenteral administration are normally presented in colourless glass, but coloured glass may be used for substances known to be light-sensitive. Colourless or coloured glass is used for the other pharmaceutical preparations. It is recommended that all glass containers for liquid preparations and for powders for parenteral administration permit the visual inspection of the contents.

The inner surface of glass containers may be specially treated to improve hydrolytic resistance, to confer water-repellancy, etc. The outer surface may also be treated, for example to reduce friction and to improve resistance to abrasion.

The outer treatment is such that it does not contaminate the inner surface of the container.

Except for type I glass containers, glass containers for pharmaceutical preparations are not to be re-used. Containers for human blood and blood components must not be re-used.

PRODUCTION

When glass containers for pharmaceutical use are manufactured under stressed conditions (e.g. temperature-time profile) and/or are placed in contact with particularly aggressive pharmaceutical preparations, they may undergo delamination, i.e the separation of the inner glass surface into thin layers called lamellae or flakes. Glass delamination may be the result of a chemical attack that occurs according to well-known glass corrosion mechanisms, such as dissolution by hydrolysis and ion exchange (leaching) as a function of the pH. The process of interaction between the glass surface and the pharmaceutical preparation requires incubation time, and flaking may only become visible a number of months after filling.

Several risk factors are known to increase the propensity of a glass to delaminate. The chemical composition of the pharmaceutical preparation, the presence of buffers like citrate or phosphate, which are known to corrode glass, and the ionic strength of the liquid medium may all strongly favour delamination. The manufacturing process of the container, chemical treatments of the inner surface, and terminal sterilisation and processing at the pharmaceutical filling lines are other important risk factors to be considered. It is recommended that the user of the container assesses the compatibility of the glass container and the pharmaceutical preparation on a case-by-case basis, considering for example the dosage form, properties of the formulation and glass quality.

The propensity to delamination of glass containers from different sources can be assessed and ranked by exposing the container to accelerated degradation testing, carried out at specified temperatures for a short time and using the solutions associated with the actual pharmaceutical preparation as extractants. The presence of particles in the extraction solution, the occurrence of phase separation on the inner surface, and the steep increase of silica concentration in the extraction solution are all indicators of a potential propensity for delamination. Accelerated degradation testing can be used as a predictive tool to select the most appropriate container for the intended preparation, but the full compatibility of the active substance with the glass leachate can only be assessed by a stability test under normal conditions of use.

TESTS

Glass containers for pharmaceutical use comply with the relevant test or tests for hydrolytic resistance. When glass containers have non-glass components, the tests apply only to the glass part of the container.

To define the quality of glass containers according to the intended use, one or more of the following tests are necessary.

Tests for hydrolytic resistance are carried out to define the type of glass (I, II or III) and to control its hydrolytic resistance.

In addition, containers for aqueous parenteral preparations are tested for arsenic release and coloured glass containers are tested for spectral transmission.

HYDROLYTIC RESISTANCE

Table 3.2.1.-1. – *Types of glass*

Type of container	Test to be performed
Type I and type II glass containers (to distinguish from type III glass containers)	Test A (surface test)
Type I glass containers (to distinguish from type II and type III glass containers)	Test B (glass grains test) or test C (etching test)
Type I and type II glass containers (if there are doubts whether the high hydrolytic resistance is due to the chemical composition or to the surface treatment)	Tests A and B, or tests A and C

The test is carried out by titration of the extraction solutions obtained under the conditions described for tests A, B and C. Test C is performed if there are uncertainties whether the container is type I or type II.

EQUIPMENT

— An autoclave or steam steriliser capable of withstanding a pressure of 2.5×10^5 N/m^2 (equivalent to 0.25 MPa = 2.5 bar) or more and capable of carrying out the heating cycle described under Autoclaving process. Preferably it is equipped with a constant-pressure regulator or other suitable means in order to maintain the temperature at 121 ± 1 °C. The autoclave vessel is equipped with a heating device, a thermometer integrated in the autoclave, a pressure gauge, a vent cock (for manually operated autoclaves only) and a tray of sufficient capacity to accommodate, above the water level, the number of containers needed to carry out the test. The autoclave has the possibility to connect a calibrated resistance thermometer or a calibrated thermocouple from the inner chamber to an external measuring device to allow a temperature measurement independent from the autoclave system.

The autoclave vessel and all ancillary equipment must be washed thoroughly with water R before use.

— A calibrated resistance thermometer or calibrated thermocouple connected to a suitable temperature measuring device.
— Burettes with a suitable capacity.
— One-mark volumetric flasks, with a capacity of 1000 mL.
— Pipettes and beakers.
— Conical flasks with capacities of 100 mL and 250 mL.
— A water-bath.
— Metal foil (e.g. aluminium, stainless steel).

Flasks and beakers must already have been used for the test or have been filled with *water R* and kept in an autoclave at 121 °C for at least 1 h before being used.

DETERMINATION OF THE FILLING VOLUME

The filling volume is the volume of water to be introduced into the container for the purpose of the test. For vials and bottles the filling volume is 90 per cent of the brimful capacity. For ampoules it is the volume up to the height of the shoulder.

Vials and bottles

Select, at random, 6 containers from the sample lot, or 3 if their capacity exceeds 100 mL, and remove any debris or dust. Weigh the empty containers with an accuracy of 0.1 g. Place the containers on a horizontal surface and fill them with *water R* until about the rim edge, avoiding overflow and introduction of air bubbles. Adjust the liquid levels to the brimful line. Weigh the filled containers to obtain the mass of

the water expressed to 2 decimal places for containers having a nominal volume less than or equal to 30 mL, and expressed to 1 decimal place for containers having a nominal volume greater than 30 mL. Calculate the mean value of the brimful capacity in millilitres and multiply it by 0.9. This volume, expressed to 1 decimal place, is the filling volume for the particular container lot.

Ampoules

Place at least 6 dry ampoules on a flat, horizontal surface and fill them with *water R* from a burette, until the water reaches point A, where the body of the ampoule declines to the shoulder (see Figure 3.2.1.-1). Read the capacities (expressed to 2 decimal places) and calculate the mean value. This volume, expressed to 1 decimal place, is the filling volume for the particular ampoule lot. The filling volume may also be determined by weighing.

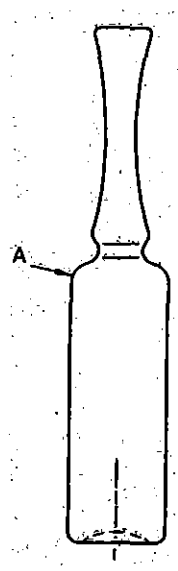

Figure 3.2.1.-1. – *Filling volume of ampoules (up to point A)*

Syringes and cartridges

Select 6 syringes or cartridges. Close the small opening (mouth of cartridges and needle and/or Luer cone of syringes) using an inert material (e.g. a tip cap) or any other suitable means to prevent water leakage. Determine the mean brimful volume in accordance with the procedure described under Vials and bottles and multiply it by 0.9. This volume, expressed to 1 decimal place, is the filling volume for the particular container lot.

TEST A. HYDROLYTIC RESISTANCE OF THE INNER SURFACES OF GLASS CONTAINERS (SURFACE TEST)

The determination is carried out on unused containers. The volumes of the test liquid necessary are indicated in Table 3.2.1.-2.

Table 3.2.1.-2. – *Volume of test liquid and number of titrations*

Filling volume (mL)	Volume of test liquid for 1 titration (mL)	Number of titrations
Up to 3	25.0	1
Above 3 and up to 30	50.0	2
Above 30 and up to 100	100.0	2
Above 100	100.0	3

Cleaning

Remove any debris or dust. Shortly before the test, fill each container to the brim with *water R* and allow to stand, filled with water, for 20 ± 5 min. Empty the containers, carefully rinse twice with *water R* and once with *water R1* and allow to drain.

Closed ampoules are not rinsed before testing. Closed ampoules may be warmed on a water-bath or in an oven at about 40 °C for approximately 2 min before opening to avoid underpressure when opening.

Filling

Fill the containers with *water R1* up to the filling volume.

Loosely cap each container with an inert material, for example with inverted beakers of such a size that the bottoms of the beakers fit snugly down on the rims of the sample. Ampoules and vials capped with clean aluminium foil are further examples. Place syringes and cartridges in a beaker and cover the beaker with clean aluminium foil.

Containers of a volume of 2 mL or less, in which the water is not sufficiently retained during the autoclaving process, may be closed in a suitable way, e.g. with a stopper or plug of inert material, such as silicone, and fixed using a plunger or a stable fixing or clamping device.

Place the samples, gathered in groups in glass dishes or in beakers or other suitable holders, on the rack in the autoclave containing *water R* at room temperature. Ensure that they are held above the level of the water in the autoclave.

Autoclaving process

Reference thermal cycle

The autoclave is run in such a way that the temperature in the containers to be tested follows a thermal cycle with the following characteristics: temperature raised from room temperature to 100 °C within 20-30 min; temperature maintained at 100 ± 1 °C for 10 ± 1 min; temperature in the containers raised from 100 °C to 121 °C within 20-22 min; temperature maintained at 121 ± 1 °C for 60 ± 1 min; temperature cooled to 100 °C within 40-44 min.

Autoclave calibration

Before being used for the first time, the autoclave and the temperature measuring system are calibrated to ensure that the autoclave settings are suitable to guarantee that the temperature inside the containers is 121 ± 1 °C.

NOTE: significant differences may be observed between the temperature measured in the autoclave chamber and inside the containers.

Take a set of containers of intermediate capacity (10 mL for instance) and fill them with *water R1*. Select a sufficient number of containers to fill completely the tray within the autoclave chamber. Insert the end of the calibrated resistance thermometer or calibrated thermocouple into one of the containers through a hole in the closure having approximately the same diameter as the probe and connect it to the external measuring device. If the container is too small to insert a thermocouple, place the thermocouple in a similar container of suitable size filled with *water R1*. Close the autoclave door or lid securely and run the autoclave to achieve the target thermal cycle in the containers. Where a manual autoclave is run, leave the vent cock open. Heat the autoclave at a regular rate so that steam issues vigorously from the vent cock after 20-30 min, and maintain a vigorous evolution of steam for a further 10 min.

Close the vent cock, follow the temperature increase on the calibrated thermocouple measuring device by comparison with readings taken from the autoclave thermometer and adjust the autoclave settings accordingly in order to match

the target thermal cycle. Keep the temperature ramp as smooth as possible.

Using the calibrated thermocouple measuring device, ensure that deviations from the holding temperature of 121 ± 1 °C are within the tolerance. When cooling down, vent to prevent the formation of a vacuum. For safety reasons (boiling retardation) do not open the autoclave before the water in the containers has reached a temperature of 95 °C. Remove the hot samples from the autoclave and cool cautiously to room temperature within 30 min.

Record the autoclave settings used to carry out the thermal cycle and use these settings for routine autoclave runs.

At regular intervals verify the validation of the calibration. Establish a re-calibration plan based on quality assurance criteria, recalibrate as appropriate and keep records.

Routine autoclave runs

Use the autoclave settings established during the calibration stage and follow the same thermal cycle described above. Container sets of different capacity can be tested during the same run. Keep the glass load very similar in size and mass to the load used during the calibration stage. The use of the calibrated thermocouple is no longer necessary provided the calibration is proved to be valid over a defined time span.

At the end of the cycle, remove the hot samples from the autoclave and cool them cautiously to room temperature within 30 min.

NOTE: depending on the type or size of the autoclave the heat transfer and thus the resulting thermal cycle in the containers may vary with the total load of the autoclave. It may therefore be necessary to adjust the autoclave load.

Method

Carry out the titration within 1 h of removal of the containers from the autoclave. Combine the liquids obtained from the containers and mix. Introduce the prescribed volume (Table 3.2.1.-2) into a conical flask (test solution). Place the same volume of *water R1* into a 2nd similar flask as a blank. Add to each flask 0.05 mL of *methyl red solution R* for each 25 mL of liquid. Titrate the blank with *0.01 M hydrochloric acid*. Titrate the test solution with the same acid until the colour of the resulting solution is the same as that obtained for the blank. Subtract the value found for the blank titration from that found for the test solution and express the results in millilitres of *0.01 M hydrochloric acid* per 100 mL. Express titration values of less than 1.0 mL to 2 decimal places and titration values of more than or equal to 1.0 mL to 1 decimal place.

Limits

The results, or the average of the results if more than 1 titration is performed, is not greater than the values stated in Table 3.2.1.-3.

Table 3.2.1.-3. – *Limit values in the test for surface hydrolytic resistance*

	Maximum volume of 0.01 M HCl per 100 mL of test solution (mL)	
Filling volume (mL)	Types I and II glass containers	Type III glass containers
Up to 0.5	3.0	30.0
Above 0.5 and up to 1	2.0	20.0
Above 1 and up to 2	1.8	17.6
Above 2 and up to 3	1.6	16.1
Above 3 and up to 5	1.3	13.2
Above 5 and up to 10	1.0	10.2
Above 10 and up to 20	0.80	8.1
Above 20 and up to 50	0.60	6.1
Above 50 and up to 100	0.50	4.8
Above 100 and up to 200	0.40	3.8
Above 200 and up to 500	0.30	2.9
Above 500	0.20	2.2

TEST B. HYDROLYTIC RESISTANCE OF GLASS GRAINS (GLASS GRAINS TEST)

Check that the articles as received have been annealed to a commercially acceptable quality.

The test may be performed on the canes used for the manufacture of tubing glass containers or on the containers.

Equipment

- a mortar, pestle (see Figure 3.2.1.-2) and hammer made of tempered, magnetic steel;
- as an alternative to the mortar, pestle and hammer, a ball mill can be used; the ball mill is made of agate, zirconia or stainless steel with a volume of 250 mL; 2 balls with a diameter of 40 mm or 3 balls with a diameter of 30 mm are suitable;
- a set of 3 square-mesh sieves of stainless steel, mounted on frames of the same material and consisting of the following:

(a) sieve no. 710;

(b) sieve no. 425;

(c) sieve no. 300;

- a mechanical sieve-shaker or a sieving machine may be used to sieve the grains;
- a permanent magnet;
- metal foil (e.g. aluminium, stainless steel);
- a hot-air oven, capable of maintaining a temperature of 140 ± 5 °C;
- a balance, capable of weighing up to 500 g with an accuracy of 0.005 g;
- a desiccator;
- an ultrasonic bath.

Method

Rinse the containers to be tested with *water R* and dry in the oven. Wrap at least 3 of the glass articles in clean paper and crush to produce 2 samples of about 100 g each, in pieces not more than 30 mm across.

Where a mortar, pestle and hammer are used, place in the mortar 30-40 g of the pieces 10-30 mm across taken from 1 of the samples, insert the pestle and strike it heavily, once only, with the hammer. Transfer the contents of the mortar to sieve (a), the coarsest of the set. Repeat the operation until all fragments have been transferred to the sieve. Shake the set of sieves for a short time by hand and remove the glass that remains on sieves (a) and (b). Submit these portions to further fracture, repeating the operation until about 10 g of glass remains on sieve (a). Reject this portion and the portion that passes through sieve (c). Reassemble the set of sieves and shake for 5 min. Transfer to a weighing bottle those glass grains that pass through sieve (b) and are retained on sieve (c).

Where a ball mill is used, place in the ball mill beaker about 50 g of the pieces 10-30 mm across taken from 1 of the samples, add the balls and crush thin-walled glass (wall thickness up to 1.5 mm) for up to 2 min and thick-walled glass (wall thickness greater than 1.5 mm) for up to 5 min. Transfer the grains to sieve (a), sieve for about 30 s and collect the grains retained on sieve (c). Transfer the glass from sieves (a) and (b) into the ball mill and crush and sieve again as indicated above. Combine the grains retained on sieve (c).

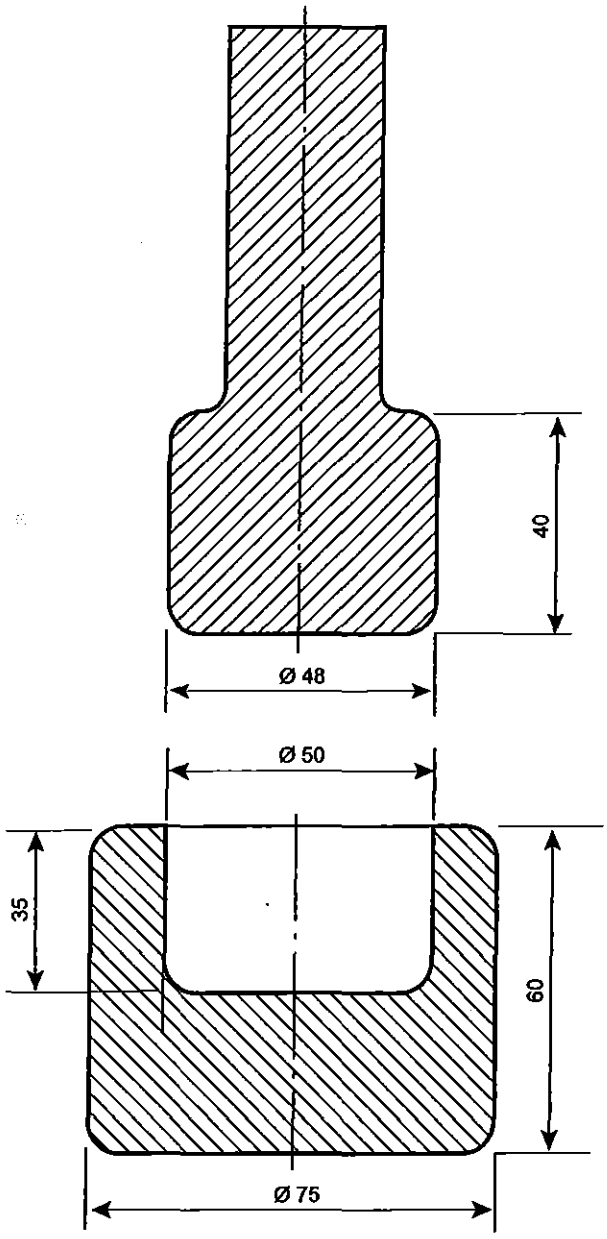

Figure 3.2.1.-2. – *Mortar and pestle apparatus for glass grains method (dimensions in millimetres)*

Repeat the crushing and sieving procedure with the other glass sample and thus 2 samples of grains, each of which shall be in excess of 10 g, are obtained. Spread each sample on a piece of clean glazed paper and remove any iron particles by passing the magnet over them. Transfer each sample into a beaker for cleaning. Add to the grains in each beaker 30 mL of *acetone R* and scour the grains by suitable means, such as a rubber- or plastic-coated glass rod. After scouring the grains, allow to settle and decant as much acetone as possible. Add another 30 mL of *acetone R*, swirl, allow to settle and decant again, and add 30 mL of *acetone R*.

Fill the bath of the ultrasonic vessel with water at room temperature, then place the beaker in the rack and immerse it until the level of the acetone is at the level of the water; apply the ultrasound for 1 min. Swirl the beaker, allow to settle and decant the acetone as completely as possible, add 30 mL of *acetone R* and repeat the ultrasonic cleaning operation. If a fine turbidity persists, repeat the ultrasonic cleaning and acetone washing until the solution remains clear. Swirl and decant the acetone then dry the grains, first by putting the beaker on a warm plate to remove excess acetone and then by heating at 140 °C for 20 min in the drying oven. Transfer the dried grains from each beaker into separate weighing bottles, insert the stoppers and cool in the desiccator. Weigh 10.00 g of the cleaned and dried grains into 2 separate conical flasks. Add 50 mL of *water R1* into each by means of a pipette (test solutions). Pipette 50 mL of *water R1* into a 3rd conical flask as a blank. Distribute the grains evenly over the flat bases of the flasks by gentle shaking. Close the flasks with neutral glass dishes or aluminium foil rinsed with *water R*, or with inverted beakers so that the inner surface of the beakers fit snugly down onto the top rims of the flasks. Place all 3 flasks in the rack in the autoclave containing the water at room temperature, and ensure that they are held above the level of the water in the vessel. Carry out the autoclaving procedure in a similar manner to that described under test A, but maintain the temperature of 121 ± 1 °C only for 30 ± 1 min. Do not open the autoclave until it has cooled to 95 °C. Remove the hot samples from the autoclave and cool the flasks in running tap water as soon as possible, avoiding thermal shock.

To each of the 3 flasks add 0.05 mL of *methyl red solution R*. Titrate the blank solution immediately with *0.02 M hydrochloric acid* then titrate the test solutions with the same acid until the colour matches that obtained with the blank solution. Subtract the titration volume for the blank solution from that for the test solution.

NOTE: where necessary to obtain a sharp end-point, the clear solution is to be decanted into a separate 250 mL flask. Rinse the grains with 3 quantities, each of 15 mL, of water R1 by swirling and add the washings to the main solution. Add 0.05 mL of methyl red solution R. Titrate and calculate as described below. In this case also add 45 mL of water R1 and 0.05 mL of methyl red solution R to the blank solution.

Calculate the mean value of the results in millilitres of *0.02 M hydrochloric acid* per gram of the sample and if required its equivalent in alkali extracted, calculated as micrograms of sodium oxide per gram of glass grains.

1 mL of *0.02 M hydrochloric acid* is equivalent to 620 µg of sodium oxide.

Repeat the test if the highest and lowest observed values differ by more than 20 per cent.

Limits

Type I glass containers require not more than 0.1 mL of *0.02 M hydrochloric acid* per gram of glass, type II and type III glass containers require not more than 0.85 mL of *0.02 M hydrochloric acid* per gram of glass.

TEST C. TO DETERMINE WHETHER THE CONTAINERS HAVE BEEN SURFACE-TREATED (ETCHING TEST)

If there are uncertainties whether a container has been surface-treated, and/or to distinguish between type I and type II glass containers, test C is used in addition to test A. Alternatively, tests A and B may be used. Test C may be carried out either on unused samples or on samples previously used in test A.

Vials and bottles

The volumes of test liquid required are shown in Table 3.2.1.-2.

Rinse the containers twice with *water R*, fill to the brimful point with a mixture of 1 volume of *hydrofluoric acid R* and 9 volumes of *hydrochloric acid R* and allow to stand for 10 min. Empty the containers and rinse carefully 5 times with *water R*. Immediately before the test, rinse once again with *water R*. Submit the containers thus prepared to the

same autoclaving and determination procedure as described in Test A for surface hydrolytic resistance. If the results are considerably higher than those obtained from the original surfaces (by about a factor of 5 to 10), the samples have been surface-treated.

Ampoules, cartridges and syringes

NOTE: ampoules, cartridges and syringes made from glass tubing are not normally subjected to internal surface treatment because their high chemical resistance is dependent upon the chemical composition of the glass as a material.

Apply the test method as described above for vials and bottles. If the ampoules are not surface-treated, the new values are slightly lower than those obtained in previous tests.

Distinction between type I and type II glass containers

The results obtained in Test C are compared to those obtained in Test A. The interpretation of the result is shown in Table 3.2.1.-4.

Table 3.2.1.-4. – *Distinction between type I and type II glass containers*

Type I	Type II
The values are closely similar to those found in the test for surface hydrolytic resistance for type I glass containers.	The values greatly exceed those found in the test for surface hydrolytic resistance and are similar to but not larger than those for type III glass containers.

ARSENIC

The test applies to glass containers for aqueous parenteral preparations.

Hydride generation atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Use the extraction solution obtained from containers of types I and II, after autoclaving at 121 °C for 1 h as described under Test A for surface hydrolytic resistance. Transfer 10.0 mL to a 100 mL volumetric flask. Add 10 mL of *hydrochloric acid R* and 5 mL of a 200 g/L solution of *potassium iodide R*. Heat on a water-bath at 80 °C for 20 min, allow to cool and dilute to 100.0 mL with *water R*.

Reference solutions Prepare the reference solutions using *arsenic standard solution (1 ppm As) R*. Add 10 mL of *hydrochloric acid R* and 5 mL of a 200 g/L solution of *potassium iodide R*. Heat on a water-bath at 80 °C for 20 min, allow to cool and dilute to 100.0 mL with *water R*. The concentration range of the reference solutions is typically 0.005-0.015 ppm of As.

Acid reservoir *Hydrochloric acid R.*

Reducing reservoir *Sodium tetrahydroborate reducing solution R.*

Use a hydride generation device to introduce the test solution into the cuvette of the spectrometer. Establish and standardise instrumental operating conditions according to the manufacturer's instructions, optimise the uptake rate of the peristaltic pump, then connect it to the acid reservoir, the reducing reservoir and the test solution.

Source Hollow-cathode lamp.

Wavelength 193.7 nm.

Atomisation device Air-acetylene flame.

Limit Maximum 0.1 ppm of As.

SPECTRAL TRANSMISSION FOR COLOURED GLASS CONTAINERS

Equipment

A UV-Vis spectrophotometer, equipped with a photodiode detector or equipped with a photomultiplier tube coupled with an integrating sphere.

Preparation of the specimen

Break the glass container or cut it with a circular saw fitted with a wet abrasive wheel, such as a carborundum or a bonded-diamond wheel. Select sections representative of the wall thickness and trim them as suitable for mounting in a spectrophotometer. If the specimen is too small to cover the opening in the specimen holder, mask the uncovered portion with opaque paper or tape, provided that the length of the specimen is greater than that of the slit. Before placing in the holder, wash, dry and wipe the specimen with a lens tissue. Mount the specimen with the aid of wax, or by other convenient means, taking care to avoid leaving fingerprints or other marks.

Method

Place the specimen in the spectrophotometer with its cylindrical axis parallel to the slit and in such a way that the light beam is perpendicular to the surface of the section and that the losses due to reflection are at a minimum. Measure the transmission of the specimen with reference to air in the spectral region of 290-450 nm, continuously or at intervals of 20 nm.

Limits

The observed spectral transmission for coloured glass containers for preparations that are not for parenteral administration does not exceed 10 per cent at any wavelength in the range of 290-450 nm, irrespective of the type and the capacity of the glass container. The observed spectral transmission in coloured glass containers for parenteral preparations does not exceed the limits given in Table 3.2.1.-5.

Table 3.2.1.-5. – *Limits of spectral transmission for coloured glass containers for parenteral preparations*

	Maximum percentage of spectral transmission at any wavelength between 290 nm and 450 nm	
Nominal volume (mL)	Flame-sealed containers	Containers with closures
Up to 1	50	25
Above 1 and up to 2	45	20
Above 2 and up to 5	40	15
Above 5 and up to 10	35	13
Above 10 and up to 20	30	12
Above 20	25	10

ANNEX – TEST FOR SURFACE HYDROLYTIC RESISTANCE – DETERMINATION BY FLAME SPECTROMETRY

The surface hydrolytic resistance of glass of types I and II may be determined by analysis of the leaching solution by flame spectrometry. A number of elements that, when present as oxides in glass, contribute to the alkalinity of the solution, are determined and used to express an alkali equivalent. The spectrometric method has the advantage of allowing the use of a much smaller sample of extract so that it can be applied to small individual containers. This enables an evaluation of the uniformity of the containers in a

given batch where this is critical. The results of this measurement are not equivalent to those of titrimetry and the 2 methods cannot be considered interchangeable. A correlation between the 2 is dependent on the type of glass and the size and shape of the container. The titrimetric method is the reference method of the Pharmacopoeia; the spectrometric method may be used in justified and authorised cases.

A method suitable for this type of analysis is shown below.

The determination is carried out on unused containers. The number of containers to be examined is indicated in Table 3.2.1.-6.

Table 3.2.1.-6. – *Number of containers to be examined for the spectrometric method*

Filling volume (mL)	Number of containers to be measured separately	Additional containers for preliminary measurements
Up to 2	20	2
Above 2 and up to 5	15	2
Above 5 and up to 30	10	2
Above 30 and up to 100	5	1
Above 100	3	1

Instructions on determination of the filling volume, cleaning of the containers, filling and heating are given above under Hydrolytic resistance and Test A.

SOLUTIONS

Spectrochemical buffer solution Dissolve 80 g of *caesium chloride R* in about 300 mL of *water R1*, add 10mL of *6 M hydrochloric acid R*, dilute to 1.0 L with *water R1* and mix.

Stock solutions:

— sodium oxide, $c(Na_2O)$ = 1 mg/mL;
— potassium oxide, $c(K_2O)$ = 1 mg/mL;
— calcium oxide, $c(CaO)$ = 1 mg/mL.

Commercially available stock solutions may also be used.

Standard solutions Prepare standard solutions by diluting the stock solutions with *water R1* to obtain concentrations suitable for establishing the reference solutions in an appropriate manner, e.g. with concentrations of 20 µg/mL of sodium oxide, potassium oxide and calcium oxide, respectively. Commercially available standard solutions may also be used.

Reference solutions Prepare the reference solutions for establishing the calibration graph (set of calibration solutions) by diluting suitable concentrated standard solutions with *water R1*, so that the normal working ranges of the specific elements are covered, taking into account the instrument used for the measurement. Typical concentration ranges of the reference solutions are:

— for determination by atomic emission spectrometry of sodium oxide and potassium oxide: up to 10 µg/mL;
— for determination by atomic absorption spectrometry of sodium oxide and potassium oxide: up to 3 µg/mL;
— for determination by atomic absorption spectrometry of calcium oxide: up to 7 µg/mL.

Use reference solutions containing 5 per cent *V/V* of the spectrochemical buffer solution.

METHOD

Carry out preliminary measurements of the potassium oxide and calcium oxide concentrations on one of the extraction solutions. If, for one container type, the concentration of potassium oxide is less than 0.2 µg/mL and the concentration of calcium oxide is less than 0.1 µg/mL, the remaining extraction solutions of this container type need not be analysed for these ions. Aspirate the extraction solution from each sample directly into the flame of the atomic absorption or atomic emission instrument and determine the approximate concentrations of sodium oxide (and potassium oxide and calcium oxide, if present) by reference to calibration graphs produced from the reference solutions of suitable concentration.

FINAL ANALYSIS

If dilution is unnecessary, add to each container a volume of the spectrochemical buffer solution equivalent to 5 per cent of the filling volume, mix well and determine sodium oxide, calcium oxide and potassium oxide, by reference to calibration graphs. For the determination of the calcium oxide concentration by flame spectrometry, a nitrous oxide/acetylene flame is used.

If dilution is necessary, determine sodium oxide, calcium oxide and potassium oxide, if present, following the procedures as described above. The solutions shall contain 5 per cent *V/V* of the spectrochemical buffer solution. Concentration values less than 1.0 µg/mL are expressed to 2 decimal places, values greater than or equal to 1.0 µg/mL to 1 decimal place. Correct the result for the buffer addition and for any dilution.

DETERMINATION

Determine the mean value of the concentration of individual oxides found in the samples tested, in micrograms of the oxide per millilitre of the extraction solution, and calculate the sum of the individual oxides, expressed as micrograms of sodium oxide per millilitre of the extraction solution, using the following mass conversion factors:

— 1 µg of potassium oxide corresponds to 0.658 µg of sodium oxide;
— 1 µg of calcium oxide corresponds to 1.105 µg of sodium oxide.

Limits

The mean value is not greater than the value given in Table 3.2.1.-7.

Table 3.2.1.-7. – *Limit values in the test for surface hydrolytic resistance by flame spectrometry, for type I and type II glass containers*

Filling volume (mL)	Limit values for the concentration of oxides, expressed as sodium oxide (µg/mL)
Up to 0.5	7.50
Above 0.5 and up to 1	5.00
Above 1 and up to 2	4.50
Above 2 and up to 3	4.10
Above 3 and up to 5	3.20
Above 5 and up to 10	2.50
Above 10 and up to 20	2.00
Above 20 and up to 50	1.50
Above 50 and up to 100	1.20
Above 100 and up to 200	1.00
Above 200 and up to 500	0.75
Above 500	0.50

C. Plastic Containers and Closures

(Plastic Containers and Closures for Pharmaceutical Use, Ph. Eur. method 3.2.2)

A plastic container for pharmaceutical use is a plastic article which contains or is intended to contain a pharmaceutical product and is, or may be, in direct contact with it. The closure is a part of the container.

Plastic containers and closures for pharmaceutical use are made of materials in which may be included certain additives; these materials do not include in their composition any substance that can be extracted by the contents in such quantities as to alter the efficacy or the stability of the product or to present a risk of toxicity.

The most commonly used polymers are polyethylene (with and without additives), polypropylene, poly(vinyl chloride), poly(ethylene terephthalate) and poly(ethylene-vinyl acetate).

The nature and amount of the additives are determined by the type of the polymer, the process used to convert the polymer into the container and the intended purpose of the container. Additives may consist of antioxidants, stabilisers, plasticisers, lubricants, colouring matter and impact modifiers. Antistatic agents and mould-release agents may be used only for containers for preparations for oral use or for external use for which they are authorised. Acceptable additives are indicated in the type specification for each material described in the Pharmacopoeia. Other additives may be used provided they are approved in each case by the competent authority responsible for the licensing for sale of the preparation.

For selection of a suitable plastic container, it is necessary to know the full manufacturing formula of the plastic, including all materials added during formation of the container so that the potential hazards can be assessed. In justified cases, further detailed information may be necessary to assess the impact on chronic use and for vulnerable patient groups. The plastic container chosen for any particular preparation should be such that:

— the ingredients of the preparation in contact with the plastic material are not significantly adsorbed on its surface and do not significantly migrate into or through the plastic,
— the plastic material does not release substances in quantities sufficient to affect the stability of the preparation or to present a risk of toxicity.

Using material or materials selected to satisfy these criteria, a number of identical type samples of the container are made by a well-defined procedure and submitted to practical testing in conditions that reproduce those of the intended use, including, where appropriate, sterilisation. In order to confirm the compatibility of the container and the contents and to ensure that there are no changes detrimental to the quality of the preparation, various tests are carried out such as verification of the absence of changes in physical characteristics, assessment of any loss or gain through permeation, detection of pH changes, assessment of changes caused by light, chemical tests and, where appropriate, biological tests.

The method of manufacture is such as to ensure reproducibility for subsequent bulk manufacture and the conditions of manufacture are chosen so as to preclude the possibility of contamination with other plastic materials or their ingredients. The manufacturer of the product must ensure that containers made in production are similar in every respect to the type samples.

For the results of the testing on type samples to remain valid, it is important that:

— there is no change in the composition of the material as defined for the type samples,
— there is no change in the manufacturing process as defined for the type samples, especially as regards the temperatures to which the plastic material is exposed during conversion or subsequent procedures such as sterilisation,
— scrap material is not used.

Recycling of excess material of well-defined nature and proportions may be permitted after appropriate validation.

Subject to satisfactory testing for compatibility of each different combination of container and contents, the materials described in the Pharmacopoeia are recognised as being suitable for the specific purposes indicated, as defined above.

Plastic Containers for Aqueous Solutions for Parenteral Infusions

(Plastic Containers for Aqueous Solutions for Infusion, Ph. Eur. method 3.2.2.1)

DEFINITION

Plastic containers for aqueous solutions for infusion are manufactured from one or more polymers, if necessary with additives. The containers described in this section are not necessarily suitable for emulsions. The polymers most commonly used are polyethylene, polypropylene and poly(vinyl chloride). The specifications of this text are to be read in conjunction with section *3.2.2. Plastic containers and closures for pharmaceutical use.*

The containers may be bags or bottles. They have a site suitable for the attachment of an infusion set designed to ensure a secure connection. They may have a site that allows an injection to be made at the time of use. They usually have a part that allows them to be suspended and which will withstand the tension occurring during use. The containers must withstand the sterilisation conditions to which they will be submitted. The design of the container and the method of sterilisation chosen are such that all parts of the containers that may be in contact with the infusion are sterilised. The containers are impermeable to micro-organisms after closure. The containers are such that after filling they are resistant to damage from accidental freezing which may occur during transport of the final preparation. The containers are and remain sufficiently transparent to allow the appearance of the contents to be examined at any time, unless otherwise justified and authorised.

The empty containers display no defects that may lead to leakage and the filled and closed containers show no leakage.

For satisfactory storage of some preparations, the container has to be enclosed in a protective envelope. The initial evaluation of storage has then to be carried out using the container enclosed in the envelope.

TESTS

Solution S

Use solution S within 4 h of preparation Fill a container to its nominal capacity with *water R* and close it, if possible using the usual means of closure; otherwise close using a sheet of pure aluminium. Heat in an autoclave so that a temperature of 121 ± 2 °C is reached within 20 min to 30 min and maintain at this temperature for 30 min. If heating at 121 °C leads to deterioration of the container, heat at 100 °C for 2 h.

Blank Prepare a blank by heating *water R* in a borosilicate-glass flask closed by a sheet of pure aluminium at the temperature and for the time used for the preparation of solution S.

Appearance of solution S
Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity
To a volume of solution S corresponding to 4 per cent of the nominal capacity of the container add 0.1 mL of *phenolphthalein solution R*. The solution is colourless. Add 0.4 mL of *0.01 M sodium hydroxide*. The solution is pink. Add 0.8 mL of *0.01 M hydrochloric acid* and 0.1 mL of *methyl red solution R*. The solution is orange-red or red.

Absorbance (*2.2.25*)
Measure the absorbance of solution S from 230 nm to 360 nm, using the blank (see solution S) as the compensation liquid. At these wavelengths, the absorbance is not greater than 0.20.

Reducing substances
To 20.0 mL of solution S add 1 mL of *dilute sulfuric acid R* and 20.0 mL of *0.002 M potassium permanganate*. Boil for 3 min. Cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a titration using 20.0 mL of the blank. The difference between the titration volumes is not greater than 1.5 mL.

Transparency
Fill a container previously used for the preparation of solution S with a volume equal to the nominal capacity of the primary opalescent suspension (*2.2.1*) diluted 1 in 200 for a container made from polyethylene or polypropylene and 1 in 400 for other containers. The cloudiness of the suspension is perceptible when viewed through the container and compared with a similar container filled with *water R*.

LABELLING
The label accompanying a batch of empty containers includes a statement of:
— the name and address of the manufacturer,
— a batch number which enables the history of the container and of the plastic material of which it is manufactured to be traced.

D. Containers for Blood and Blood Components

1. Sterile Plastic Containers for Human Blood and Blood Components

(Ph. Eur. method 3.3.4)

Plastic containers for the collection, storage, processing and administration of blood and its components are manufactured from one or more polymers, if necessary with additives. The composition and the conditions of manufacture of the containers are registered by the appropriate competent authorities in accordance with the relevant national legislation and international agreements.

When the composition of the materials of the different parts of the containers corresponds to the appropriate specifications, their quality is controlled by the methods indicated in those specifications (see *3.1. Materials used for the manufacture of containers* and subsections and *3.3. Containers for human blood and blood components, and materials used in their manufacture; transfusion sets and materials used in their manufacture; syringes* and subsections).

Materials other than those described in the Pharmacopoeia may be used provided that their composition is authorised by the competent authority and that the containers manufactured from them comply with the requirements prescribed in this general chapter.

In normal conditions of use the materials do not release monomers, or other substances, in amounts likely to be harmful nor do they lead to any abnormal modifications of the blood.

Components of inks, glues or adhesives used for marking or on the labels do not migrate into the contents of the container in quantities sufficient to affect the stability of the contents or to present a risk of toxicity.

The containers may contain anticoagulant solutions, depending on their intended use, and are supplied sterile.

Each container is fitted with attachments suitable for the intended use. The container may be in the form of a single unit or the collecting container may be connected by one or more tubes to one or more secondary containers to allow separation of the blood components to be effected within a closed system.

The outlets are of a shape and size allowing for adequate connection of the container with the blood-giving equipment. The protective coverings on the blood-taking needle and on the appendages must be such as to ensure the maintenance of sterility. They must be easily removable but must be tamper-evident.

The capacity of the containers is related to the nominal capacity prescribed by the national authorities and to the appropriate volume of anticoagulant solution. The nominal capacity is the volume of blood to be collected in the container. The containers are of a shape such that when filled they may be centrifuged.

The containers are fitted with a suitable device for suspending or fixing which does not hinder the collection, storage, processing or administration of the blood.

CHARACTERS
The container is sufficiently transparent to allow adequate visual examination of its contents before and after the taking of the blood and is sufficiently flexible to offer minimum resistance during filling and emptying under normal conditions of use. The container contains not more than 5 mL of air.

TESTS

Solution S_1
Fill the container with 100 mL of a sterile, pyrogen-free 9 g/L solution of *sodium chloride R*. Close the container and heat it in an autoclave so that the contents are maintained at 110 °C for 30 min.

If the container to be examined contains an anticoagulant solution, first empty it, rinse the container with 250 mL of *water R* at 20 ± 1 °C and discard the rinsings.

Solution S_2
Introduce into the container a volume of *water R* corresponding to the intended volume of anticoagulant solution. Close the container and heat it in an autoclave so that the temperature of the water is maintained at 110 °C for 30 min. After cooling, add sufficient *water R* to fill the container to its nominal capacity.

If the container to be examined contains an anticoagulant solution, first empty it and rinse it as indicated above.

Resistance to centrifugation
Introduce into the container a volume of *water R*, acidified by the addition of 1 mL of *dilute hydrochloric acid R*, sufficient to fill it to its nominal capacity. Envelop the container with absorbent paper impregnated with a 1 in 5 dilution of *bromophenol blue solution R1* or other suitable indicator and then dried. Centrifuge at 5000 *g* for 10 min. No leakage perceptible on the indicator paper and no permanent distortion occur.

Resistance to stretch
Introduce into the container a volume of *water R*, acidified by the addition of 1 mL of *dilute hydrochloric acid R*, sufficient to fill it to its nominal capacity. Suspend the container by the suspending device at the opposite end from the blood-taking tube and apply along the axis of this tube an immediate force of 20 N (2.05 kgf). Maintain the traction for 5 s. Repeat the test with the force applied to each of the parts for filling and emptying. No break and no deterioration occur.

Leakage
Place the container which has been submitted to the stretch test between two plates covered with absorbent paper impregnated with a 1 in 5 dilution of *bromophenol blue solution R1* or other suitable indicator and then dried. Progressively apply force to the plates to press the container so that its internal pressure (i.e. the difference between the applied pressure and atmospheric pressure) reaches 67 kPa within 1 min. Maintain the pressure for 10 min. No signs of leakage are detectable on the indicator paper or at any point of attachment (seals, joints, etc.).

Vapour permeability
For a container containing an anticoagulant solution, fill with a volume of a 9 g/L solution of *sodium chloride R* equal to the volume of blood for which the container is intended.

For an empty container, fill with the same mixture of anticoagulant solution and sodium chloride solution. Close the container, weigh it and store it at 5 ± 1 °C in an atmosphere with a relative humidity of (50 ± 5) per cent for 21 days. At the end of this period the loss in mass is not greater than 1 per cent.

Emptying under pressure
Fill the container with a volume of *water R* at 5 ± 1 °C equal to the nominal capacity. Attach a transfusion set without an intravenous cannula to one of the connectors. Compress the container so as to maintain throughout the emptying an internal pressure (i.e the difference between the applied pressure and atmospheric pressure) of 40 kPa. The container empties in less than 2 min.

Speed of filling
Attach the container by means of the blood-taking tube fitted with the needle to a reservoir containing a suitable solution having a viscosity equal to that of blood, such as a 335 g/L solution of *sucrose R* at 37 °C. Maintain the internal pressure of the reservoir (i.e. the difference between the applied pressure and atmospheric pressure) at 9.3 kPa with the base of the reservoir and the upper part of the container at the same level. The volume of liquid which flows into the container in 8 min is not less than the nominal capacity of the container.

Resistance to temperature variations
Place the container in a suitable chamber having an initial temperature of 20-23 °C. Cool it rapidly in a deep-freeze to −80 °C and maintain it at this temperature for 24 h. Raise the temperature to 50 °C and maintain for 12 h. Allow to cool to room temperature. The container complies with the tests for resistance to centrifugation, resistance to stretch, leakage, vapour permeability emptying under pressure and speed of filling prescribed above.

Transparency
Fill the empty container with a volume equal to its nominal capacity of the primary opalescent suspension (*2.2.1*) diluted so as to have an absorbance (*2.2.25*) at 640 nm of 0.37 to 0.43 (dilution factor about 1 in 16). The cloudiness of the suspension must be perceptible when viewed through the bag, as compared with a similar container filled with *water R*.

Extractable matter
Tests are carried out by methods designed to simulate as far as possible the conditions of contact between the container and its contents which occur in conditions of use.

The conditions of contact and the tests to be carried out on the eluates are prescribed, according to the nature of the constituent materials, in the particular requirements for each type of container.

Haemolytic effects in buffered systems
Stock buffer solution Dissolve 90.0 g of *sodium chloride R*, 34.6 g of *disodium hydrogen phosphate dodecahydrate R* and 2.43 g of *sodium dihydrogen phosphate R* in *water R* and dilute to 1000 mL with the same solvent.

Buffer solution A_0 To 30.0 mL of stock buffer solution add 10.0 mL of *water R*.

Buffer solution B_0 To 30.0 mL of stock buffer solution add 20.0 mL of *water R*.

Buffer solution C_0 To 15.0 mL of stock buffer solution add 85.0 mL of *water R*.

Introduce 1.4 mL of solution S_2 into each of three centrifuge tubes. To tube I add 0.1 mL of buffer solution A_0, to tube II add 0.1 mL of buffer solution B_0 and to tube III add 0.1 mL of buffer solution C_0. To each tube add 0.02 mL of fresh, heparinised human blood, mix well and warm on a water-bath at 30 ± 1 °C for 40 min. Use blood collected less than 3 h previously or blood collected into an anticoagulant citrate-phosphate-dextrose solution (CPD) less than 24 h previously.

Prepare three solutions containing, respectively:

3.0 mL of buffer solution A_0 and 12.0 mL of *water R* (solution A_1),

4.0 mL of buffer solution B_0 and 11.0 mL of *water R* (solution B_1),

4.75 mL of buffer solution B_0 and 10.25 mL of *water R* (solution C_1).

To tubes I, II and III add, respectively, 1.5 mL of solution A_1, 1.5 mL of solution B_1 and 1.5 mL of solution C_1. At the same time and in the same manner, prepare three other tubes, replacing solution S_2 by *water R*. Centrifuge simultaneously the tubes to be examined and the control tubes at exactly 2500 *g* in the same horizontal centrifuge for 5 min. After centrifuging, measure the absorbances (*2.2.25*) of the liquids at 540 nm using the stock buffer solution as compensation liquid. Calculate the haemolytic value as a percentage from the expression:

$$\frac{A_{exp}}{A_{100}} \times 100$$

A_{100} = absorbance of tube III;
A_{exp} = absorbance of tube I or II or of the corresponding control tubes.

The solution in tube I gives a haemolytic value not greater than 10 per cent and the haemolytic value of the solution in

tube II does not differ by more than 10 per cent from that of the corresponding control tube.

Sterility (*2.6.1*)
The containers comply with the test for sterility. Introduce aseptically into the container 100 mL of a sterile 9 g/L solution of sodium chloride and shake the container to ensure that the internal surfaces have been entirely wetted. Filter the contents of the container through a membrane filter and place the membrane in the appropriate culture medium, as prescribed in the test for sterility.

Pyrogens (*2.6.8*)
Solution S_1 complies with the test for pyrogens. Inject 10 mL of the solution per kilogram of the rabbit's mass.

STORAGE
Containers are enclosed in sealed, protective envelopes.

Protective envelopes are sealed in such a manner that they cannot be opened and re-closed without leaving visible traces that the seal has been broken.

LABELLING
The labelling complies with the relevant national legislation and international agreements.

2. Empty Sterile Containers of Plasticised Poly(vinyl chloride) for Human Blood and Blood Components

(Ph. Eur. method 3.3.5)

This general chapter is published for information.

DEFINITION
Unless otherwise authorised as described in general chapter *3.3.4. Sterile plastic containers for human blood and blood components*, the nature and composition of the material from which the containers are made comply with the requirements in general chapter *3.3.2. Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components.*

TESTS
They comply with the tests prescribed in general chapter *3.3.4. Sterile plastic containers for human blood and blood components* and with the following tests.

Reference solution
Heat *water R* in a borosilicate-glass flask in an autoclave at 110 °C for 30 min.

Acidity or alkalinity
To a volume of solution S_2 (see *3.3.4*) corresponding to 4 per cent of the nominal value of the container add 0.1 mL of *phenolphthalein solution R*. The solution remains colourless. Add 0.4 mL of *0.01 M sodium hydroxide*. The solution is pink. Add 0.8 mL of *0.01 M hydrochloric acid* and 0.1 mL of *methyl red solution R*. The solution is orange-red or red.

Absorbance (*2.2.25*)
Maximum 0.30, determined between wavelengths of 230 nm and 250 nm on solution S_2 (see *3.3.4*); maximum 0.10, determined between wavelengths of 251 nm and 360 nm on solution S_2. Use the reference solution as the compensation liquid.

Reducing substances
Immediately after preparation of solution S_2 (see *3.3.4*), transfer to a borosilicate-glass flask a volume corresponding to 8 per cent of the nominal value of the container. At the same time, prepare a blank using an equal volume of the freshly prepared reference solution in another borosilicate-glass flask. To each solution add 20.0 mL of *0.002 M potassium permanganate* and 1 mL of *dilute sulfuric acid R*. Allow to stand protected from light for 15 min. To each solution add 0.1 g of *potassium iodide R*. Allow to stand protected from light for 5 min and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. The difference between the 2 titrations is not greater than 2.0 mL.

Plastic additives 01, 24, 25, 26 and 27
Gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*).

Internal standard solution S3 1 mg/mL solution of *di-n-octyl phthalate R* in *tetrahydrofuran for chromatography R.*

Internal standard solution S4 5 µg/mL solution of *di-n-octyl phthalate R* in *anhydrous ethanol R.*

Test solution Cut 0.2 g of the material to be examined into pieces about 0.5 cm in length. Dissolve the pieces in 12.5 mL of internal standard solution S3 using a polytetrafluoroethylene magnetic stirring bar. Complete dissolution of the material to be examined is obtained after stirring for about 20-30 min. The poly(vinyl chloride) is precipitated as a white powder by adding dropwise 37.5 mL of *anhydrous ethanol R*. Centrifuge, then dilute 1.0 mL of the supernatant to 50.0 mL with *anhydrous ethanol R*. The final concentration of the internal standard in the test solution is 5 µg/mL.

The stock solutions may be stored at 4 °C for up to 2 weeks.

Stock solution (a) Dissolve 20.0 mg of *plastic additive 01 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (b) Dissolve 20.0 mg of *plastic additive 24 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (c) Dissolve 20.0 mg of *plastic additive 25 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (d) Dissolve 20.0 mg of *plastic additive 26 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (e) Dissolve 20.0 mg of *plastic additive 27 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Reference solutions (a1)-(a5) Dilute stock solution (a) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 01 CRS.*

Reference solutions (b1)-(b5) Dilute stock solution (b) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 24 CRS.*

Reference solutions (c1)-(c5) Dilute stock solution (c) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 25 CRS.*

Reference solutions (d1)-(d5) Dilute stock solution (d) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 26 CRS.*

Reference solutions (e1)-(e5) Dilute stock solution (e) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 27 CRS.*

Column:
- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

Carrier gas *helium for chromatography R.*

Flow rate 1 mL/min.

Split ratio 1:20.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 3.3	100 → 200
	3.3 - 20	200 → 250
	20 - 22.5	250
	22.5 - 23	250 → 270
	23 - 25	270
	25 - 25.6	270 → 320
	25.6 - 30.6	320
Injection port		300

Detection Mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:
- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- *ion source temperature*: 230 °C;
- *acquisition system*: performed on full-scan (*m/z* = 40-350) and on single-ion monitoring (SIM) modes;
- *solvent delay*: 2.5 min;
- mass spectrometer parameters for the fragmentometric mode (SIM) set as follows:

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]
Plastic additive 01	149	167	279
Plastic additive 24	155	127	299
Plastic additive 25	71	213	315
Plastic additive 26	305	193	323
Plastic additive 27	261	149	167
DnOP (internal standard)	149	279	167

Injection 1 µL.

Relative retention With reference to di-*n*-octyl phthalate (retention time = about 22 min): plastic additive 01 = about 0.80; plastic additive 24 = about 0.95-1.09; plastic additive 27 = about 1.02; plastic additive 25 = about 1.14; plastic additive 26 = about 1.34.

The specificity of the detection is checked by monitoring 3 different ions for each substance using a mass spectrometer in SIM mode. Ion ratios are determined from the peak areas after the injection of a standard solution. The ratios in the table below are given for information.

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]	Ion ratio 2/1 (%)	Ion ratio 3/1 (%)
Plastic additive 01	149	167	279	50	30
Plastic additive 24	155	127	299	30	13
Plastic additive 25	71	213	315	45	20
Plastic additive 26	305	193	323	55	20
Plastic additive 27	261	149	167	130	85
DnOP (internal standard)	149	279	167	/	/

System suitability:
- *resolution*: if plastic additive 27 is tested, minimum 1.5 between the peaks due to the internal standard and plastic additive 27;
- *repeatability*: maximum relative standard deviation of 1.0 per cent for the retention time of the peak due to the plastic additive, determined on 6 injections of a reference solution of each plastic additive tested situated in the middle of the calibration range (e.g. 20 µg/mL); maximum relative standard deviation of 3.0 per cent for the ratio of the area of the peak due to the plastic additive to that due to the internal standard, determined on 6 injections of a reference solution of each plastic additive tested situated in the middle of the calibration range (e.g. 20 µg/mL).

From the calibration curve obtained with the reference solutions, calculate the percentage content of plastic additives in the material to be examined.

Limits:
- *plastic additive 01*: maximum 40 per cent;
- *plastic additive 24*: maximum 45 per cent;
- *plastic additive 25*: maximum 45 per cent;
- *plastic additive 26*: maximum 45 per cent;
- *plastic additive 27*: maximum 45 per cent.

Chlorides (*2.4.4*)

Maximum 0.4 ppm, determined with solution S_2 (see *3.3.4*).

Prepare the standard using a mixture of 1.2 mL of *chloride standard solution (5 ppm Cl) R* and 13.8 mL of *water R*.

Residue on evaporation

Evaporate to dryness 100 mL of solution S_2 (see *3.3.4*) in a borosilicate-glass beaker of appropriate capacity, previously heated to 105 °C. Evaporate to dryness in the same conditions 100 mL of the reference solution (blank test). Dry to constant mass at 100-105 °C. The residue from solution S_2 weighs a maximum of 3 mg, taking into account the blank test.

STORAGE

See general chapter *3.3.4. Sterile plastic containers for human blood and blood components.*

LABELLING

See general chapter *3.3.4. Sterile plastic containers for human blood and blood components.*

3. Sterile Containers of Plasticised Poly(vinyl chloride) for Human Blood Containing Anticoagulant Solution

(Ph. Eur. method 3.3.6)

This general chapter is published for information.

DEFINITION

Sterile plastic containers containing an anticoagulant solution complying with the monograph *Anticoagulant and preservative solutions for human blood (0209)* are used for the collection, storage and administration of blood. Before filling they comply with the description and characters given in general chapter *3.3.5. Empty sterile containers of plasticised poly(vinyl chloride) for human blood and blood components.*

Unless otherwise authorised as described in general chapter *3.3.4. Sterile plastic containers for human blood and blood components*, the nature and composition of the material from which the containers are made comply with the requirements prescribed in general chapter *3.3.2. Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components.*

TESTS

They comply with the tests prescribed in general chapter *3.3.4. Sterile plastic containers for human blood and blood components* and with the following tests.

Volume of anticoagulant solution
Empty the container, collecting the anticoagulant solution in a graduated cylinder. The volume does not differ by more than ± 10 per cent from the stated volume.

Absorbance (*2.2.25*)
Measure the absorbance of the anticoagulant solution removed from the container between 250 nm and 350 nm, using as the compensation liquid an anticoagulant solution of the same composition that has not been in contact with a plastic material. The absorbance at the maximum at 280 nm is not greater than 0.5.

Plastic additives 01, 24, 25, 26 and 27
Gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*).

Carefully remove the anticoagulant solution by means of the flexible transfer tube. Using a funnel fitted to the tube, completely fill the container with *water R*, leave in contact for 1 min while squeezing the container gently, then empty completely. Repeat the rinsing. The container, emptied and rinsed in this manner, complies with the test for plastic additives 01, 24, 25, 26 and 27 prescribed in general chapter *3.3.5. Empty sterile containers of plasticised poly(vinyl chloride) for human blood and blood components.*

STORAGE
See general chapter *3.3.4. Sterile plastic containers for human blood and blood components.*

LABELLING
See general chapter *3.3.4. Sterile plastic containers for human blood and blood components.*

E. Rubber Closures for Containers for Aqueous Parenteral Preparations

(Rubber Closures for Containers for Aqueous Parenteral Preparations for Powders and for Freeze-dried Powders, Ph. Eur. method 3.2.9)

Rubber closures for containers for aqueous parenteral preparations, for powders and for freeze-dried powders are elastomers made of materials obtained by vulcanisation (cross-linking) of macromolecular organic substances, using appropriate additives. They cover all types of rubber closures including stoppers for vials, sealing disks and plunger stoppers for cartridges, as well as rubber tip caps, needle shields and plunger stoppers for syringes. The elastomers are polymers, obtained by chemical synthesis, or are polymers of natural origin. The choice of the principal components and of the various additives (for example, vulcanisers, accelerators, stabilisers, pigments) depends on the properties required for the finished article. The specifications apply to rubber closures made from rubber of 1 kind only, to coated closures, to bi-layer seals and to lubricated closures. Coated closures consist of a bulk of rubber, bearing on its surface or part of its surface a layer of a different polymer. Bi-layer seals are composed of 2 different layers of rubber, 1 of which exhibits a higher level of chemical purity and is intended for contact with a pharmaceutical preparation; the other layer exhibits a higher level of elasticity and is intended to improve self-sealing and fragmentation resistance of the seal. Lubricated rubber closures are closures treated with silicone oil (*3.1.8*) or other lubricants, for example materials chemically or mechanically bonded to the closures.

If closures are lubricated they comply in lubricated state with the requirements as defined in this general chapter.
The specifications do not apply to closures made from silicone elastomer (which are dealt with in general chapter *3.1.9. Silicone elastomer for closures and tubing*).

Rubber closures may be classified in 2 types: type I closures meet the strictest requirements and are preferred; type II closures have mechanical properties suitable for special uses (for example, multiple piercing) and cannot meet requirements as severe as for type I closures because of their chemical composition.

The closures chosen for use with a particular preparation are such that:
- the components of the preparation in contact with the closures are not adsorbed onto the surface of the closures and do not migrate into or through the closures to an extent sufficient to affect the preparation adversely;
- the closures do not release substances in quantities sufficient to affect the stability of the preparation or to present a risk of toxicity;
- the closures are compatible with the preparation for which they are used throughout its period of validity.

The manufacturer of the preparation must obtain from the supplier an assurance that the composition of the closure does not vary and that it is identical to that of the closure used during compatibility testing. If the supplier informs the manufacturer of the preparation that changes have been made to the composition, a risk assessment should be applied to determine the need to repeat the compatibility testing, totally or partly, depending on the nature of the changes.

The closures are washed and may be sterilised before use.

CHARACTERS
Rubber closures are elastic. They are translucent or opaque and have no characteristic colour, the latter depending on the additives used. They are practically insoluble in tetrahydrofuran, in which, however, a considerable reversible swelling may occur. They are homogeneous and practically free from flash and adventitious materials (for example, fibres, foreign particles, waste rubber).

IDENTIFICATION
Identification of the type of rubber used for the closures is not within the scope of this specification. The identification tests given below distinguish between closures made from rubber and those made from silicone elastomer and plastic materials but do not differentiate all types of rubber. Other identity tests may be carried out with the aim of detecting differences in a batch compared with the closures used for compatibility testing. One or more of the following analytical methods may be applied for this purpose: determination of relative density, determination of sulfated ash, determination of sulfur content, thin-layer chromatography carried out on an extract, ultraviolet absorption spectrophotometry of an extract, infrared absorption spectrophotometry of a pyrolysate or attenuated total reflectance (ATR).

A. Infrared absorption spectrophotometry (*2.2.24*).
Examine by attenuated total reflectance (ATR).

If necessary, cut the sample along an appropriate axis and examine the cut surface. For coated, bi-layer and lubricated closures, perform the test for each different part of the closure. This is not required for silicone oil used as lubricant. Identification of silicone oil can be performed prior to it being used.

Comparison Type sample.

If direct ATR measurement on the surface is not feasible (mainly rubber closures filled with carbon black), heat an

appropriate amount of rubber in a heat-resistant test-tube over an open flame to dry the sample and continue heating until pyrolysate vapours are condensed near the top edge of the test-tube. Examine the pyrolysate of the sample by ATR and compare the spectrum with that obtained with the pyrolysate of the type sample.

B. Total ash (*2.4.16*).

If the sample has not been subjected to steam sterilisation, drying at 100-105 °C can be omitted. Determine the percentage content of total ash in the sample to be examined and compare with the percentage content of total ash in the type sample (A_0). The total ash content falls within the following ranges depending on the total ash content of the type sample, or, if not available, in the range defined as the target for the specific rubber type.

Total ash in the type sample, A_0 (per cent)	Limit for total ash in the sample (per cent)
$A_0 \leq 5.0$	$(A_0 - 0.75)$ to $(A_0 + 0.75)$
$5.0 < A_0 \leq 10$	$(A_0 - 1.0)$ to $(A_0 + 1.0)$
$A_0 > 10$	$(A_0 - 2.0)$ to $(A_0 + 2.0)$

In addition to the use of platinum and silica crucibles described in general chapter *2.4.16*, porcelain crucibles may be used. The sample may be ignited using a microwave oven instead of a muffle furnace.

TESTS

Solution S

Place a number of uncut closures with a total surface area of about 100 cm^2 in a wide-necked flask (type I glass, *3.2.1*), add 200 mL of *water R* and weigh. Cover the mouth of the flask with a borosilicate-glass beaker. Heat in an autoclave so that a temperature of 121 ± 2 °C is reached within 20-30 min and maintain at this temperature for 30 min. Immerse the temperature probe for the autoclave programme-control in water in a container comparable to that used for the sample. Cool to room temperature over about 30 min. Make up to the original mass with *water R*. Shake and decant the solution immediately. Shake solution S before each test. If using a tightly closed flask (type I glass, *3.2.1*) with an inert closure instead of a wide-necked flask covered with a borosilicate-glass beaker, it is not necessary to make up to the original mass.

Blank solution Prepare a blank solution in the same manner using 200 mL of *water R*.

Appearance of solution S

Solution S is not more intensely coloured than reference solution GY_5 (*2.2.2, Method II*). For type I closures, solution S is not more opalescent than reference suspension II (*2.2.1*) and for type II closures, solution S is not more opalescent than reference suspension III. In case of nephelometric determination, the limit for type I closures is 6 NTU and the limit for type II closures is 18 NTU.

Acidity or alkalinity

To 20 mL of solution S add 0.1 mL of *bromothymol blue solution R1*. Carry out a titration using 20.0 mL of the blank (see solution S). Not more than 0.3 mL of *0.01 M sodium hydroxide* or 0.8 mL of *0.01 M hydrochloric acid* is required to change the colour of the indicator to blue or yellow, respectively. If after adding the indicator the solution is green, it is neutral and no titration is needed.

Absorbance

Carry out the test within 5 h of preparation of solution S. Filter solution S through a membrane filter (nominal pore size 0.45 µm), rejecting the first few millilitres of filtrate. Measure the absorbance (*2.2.25*) of the filtrate at wavelengths from 220-360 nm using the blank (see solution S) as compensation liquid: absorbance within the 220-360 nm range does not exceed 0.2 for type I closures or 4.0 for type II closures. If necessary, dilute the filtrate before measurement of the absorbance and correct the result for the dilution.

Reducing substances

Carry out the test within 4 h of preparation of solution S. To 20.0 mL of solution S add 1 mL of *dilute sulfuric acid R* and 20.0 mL of *0.002 M potassium permanganate*. Boil for 3 min. Cool. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a titration using 20.0 mL of the blank (see solution S). The difference between the titration volumes is not greater than 3.0 mL for type I closures and 7.0 mL for type II closures.

Ammonium (*2.4.1, Method A*)

Maximum 2 ppm.

Dilute 5 mL of solution S to 14 mL with *water R*.

Extractable zinc

Maximum 5 µg of extractable Zn per millilitre of solution S.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Use solution S. If results are outside the calibration range, dilute 10.0 mL of solution S to an appropriate volume with *0.1 M hydrochloric acid*.

Reference solutions Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R* diluted with *0.1 M hydrochloric acid*.

Source Zinc hollow-cathode lamp.

Wavelength 213.9 nm.

Atomisation device Air-acetylene flame.

Extractable heavy metals (*2.4.8*)

Maximum 2 ppm.

Solution S complies with test A. Prepare the reference solution using *lead standard solution (2 ppm Pb) R*.

Residue on evaporation

Evaporate 50.0 mL of solution S to dryness on a water-bath and dry at 100-105 °C. The residue weighs not more than 2.0 mg for type I closures and not more than 4.0 mg for type II closures.

Volatile sulfides

Place closures, cut if necessary, with a total surface area of 20 ± 2 cm^2 in a 100 mL conical flask and add 50 mL of a 20 g/L solution of *citric acid monohydrate R*. Place a piece of *lead acetate paper R* over the mouth of the flask and maintain the paper in position by placing over it an inverted weighing bottle. Heat in an autoclave at 121 ± 2 °C for 30 min. Any black stain on the paper is not more intense than that of a standard, treated in the same manner, prepared by mixing 50 mL of a 20 g/L solution of *citric acid monohydrate R* and 5.0 mL of a freshly prepared 0.0308 g/L solution of *sodium sulfide R*.

The tests for penetrability, fragmentation and self-sealing are performed on whole closures.

For the tests for penetrability, fragmentation and self-sealing, treat non-sterilised closures as described for the preparation of solution S and allow to dry. To perform these 3 tests, use for each closure a new, lubricated, long-bevel[1] (bevel angle 12 ± 2°) hypodermic needle with an external diameter of 0.8 mm and

[1] *See ISO 7864, Sterile hypodermic needles for single use.*

pierce the closures with the needle perpendicular to the surface without rotating the needle.

Penetrability
For closures intended to be pierced by a hypodermic needle, carry out the following test. Fill 10 suitable vials to the nominal volume with *water R*, fit the closures to be examined and secure with a cap. The force required for piercing, determined with an accuracy of ± 0.25 N, is not greater than 10 N for each closure.

Fragmentation
For closures intended to be pierced by a hypodermic needle, carry out the following test. If the closures are to be used for aqueous preparations, introduce in 12 clean vials a volume of *water R* corresponding to the nominal volume minus 4 mL, close the vials with the closures to be examined, secure with a cap and allow to stand for 16 h. If the closures are to be used with dry preparations, close 12 clean vials with the closures to be examined. Using a needle fitted to a clean syringe, inject into the vial 1 mL of *water R* and remove 1 mL of air; carry out this operation 4 times for each closure, piercing the closure each time at a different site. Use a new needle for each closure and check that the needle is not blunted during the test. Pass the liquid in the vials through a filter with a pore size of 0.5 µm. Count the fragments of rubber visible to the naked eye. The total number of fragments does not exceed 5. This limit is based on the assumption that fragments with a diameter equal to or greater than 50 µm are visible to the naked eye; in cases of doubt or dispute, the fragments are examined with a microscope to verify their nature and size.

Self-sealing test
For closures intended to be used with multidose containers, carry out the following test. Fill 10 vials matching the design of the stopper to the nominal volume with *water R*, fit the closures to be examined, secure with a cap and crimp tightly. Pierce each closure 10 times, piercing the closure each time at a different site. Immerse the vials upright in a 1 g/L solution of *methylene blue R* and reduce the external pressure by 27 kPa for 10 min. Restore atmospheric pressure and leave the vials immersed for 30 min. Rinse the outside of the vials. None of the vials contains any trace of coloured solution.

F. Sets for the Transfusion of Blood and Blood Components

(Ph. Eur. method 3.3.7)

This general chapter is published for information.

DEFINITION
Sets for the transfusion of blood and blood components consist principally of plastic tubing to which are fitted the parts necessary to enable the set to be used for transfusion in the appropriate manner. Sets include a closure-piercing device, a blood filter, a drip chamber, a flow regulator, a Luer connector and, usually, a site that allows an injection to be made at the time of use. When the sets are to be used with containers requiring an air filter, this may be incorporated in the closure-piercing device or a separate air-inlet device may be used. The chamber enclosing the blood filter, the drip chamber and the main tubing are transparent. The materials chosen and the design of the set are such as to ensure absence of haemolytic effects. The sets comply with current standards regarding dimensions and performance.

All parts of the set that may be in contact with blood and blood components are sterile and pyrogen-free. Each set is presented in an individual package that maintains the sterility of the contents. The sets are not to be re-sterilised or re-used.

Sets for the transfusion of blood and blood components are manufactured within the framework of a suitable quality system and in accordance with any relevant national regulations.

TESTS
Carry out the tests on sterilised sets.

Solution S
Make a closed circulation system from 3 sets and a 300 mL borosilicate-glass vessel. Fit to the vessel a suitable thermostat device that maintains the temperature of the liquid in the vessel at 37 ± 1 °C. Circulate 250 mL of *water R* through the system in the direction used for transfusion for 2 h at a rate of 1 L/h (for example using a peristaltic pump applied to as short a piece of suitable silicone elastomer tubing as possible). Collect the whole of the solution and allow to cool.

Appearance of solution
Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity
To 25 mL of solution S add 0.15 mL of *BRP indicator solution R*. Not more than 0.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue.
To 25 mL of solution S add 0.2 mL of *methyl orange solution R*. Not more than 0.5 mL of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator.

Absorbance (*2.2.25*)
Maximum 0.30, determined between wavelengths of 230 nm and 250 nm on solution S; maximum 0.15, determined between wavelengths of 251 nm and 360 nm on solution S.

Reducing substances
Carry out the test within 4 h of preparation of solution S To 20.0 mL of solution S add 1 mL of *dilute sulfuric acid R* and 20.0 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate with *0.01 M sodium thiosulfate* using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration using 20.0 mL of *water R*. The difference between the 2 titration volumes is not greater than 2.0 mL.

Ethylene oxide
Head-space gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*). *Carry out the test on each plastic part of the set for transfusion and prepare the reference solutions immediately before use.*

Test sample For hard plastic materials (e.g. cyclo-olefin polymers and copolymers), crush the sample into fine particles. For soft plastic materials (e.g. silicone or plasticised poly(vinyl chloride)), cut the sample into pieces not greater than 0.5 cm^2 in size. In both cases, weigh 0.10-3.00 g of the sample, depending on the amount of ethylene oxide residue expected in the plastic part tested, into a 20 mL injection vial and close the vial. For low ethylene-oxide-releasing plastic materials (e.g. cyclo-olefin polymers and copolymers), heat the vial in an oven at 120 °C for at least 15 h (pre-thermal extraction step) before the 1st injection.

Reference solution (a) Dilute 1.0 mL of *ethylene oxide stock solution R1* to 50.0 mL with *anhydrous ethanol R* (1000 µg of ethylene oxide per millilitre). *If the solution is prepared using commercial ethylene oxide standard from a previously opened container, it should be noted that some ethylene oxide may have been lost owing to its high volatility.*

Reference solution (b) Dilute 10 mL of reference solution (a) to 20 mL with *anhydrous ethanol R* (500 µg of ethylene oxide per millilitre).

Reference solution (c) Dilute 8.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (400 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (c) into an injection vial and close immediately.

Reference solution (d) Dilute 6.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (300 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (d) into an injection vial and close immediately.

Reference solution (e) Dilute 4.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (200 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (e) into an injection vial and close immediately.

Reference solution (f) Dilute 2.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (100 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (f) into an injection vial and close immediately.

Reference solution (g) Dilute 1.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (50 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (g) into an injection vial and close immediately.

Reference solution (h) Dilute 0.5 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (25 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (h) into an injection vial and close immediately.

Reference solution (i) Dilute 100 mg of *acetaldehyde R* to 100 mL with *anhydrous ethanol R* (1000 µg of *acetaldehyde R* per millilitre).

Reference solution (j) Transfer 10 µL of reference solution (i) and 20 µL of reference solution (b) into an injection vial, mix and close immediately.

Column:
- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.32 mm;
- *stationary phase*: *porous silica for chromatography R* (film thickness 4 µm).

A particle trap may be used to prevent particles that are dislodged from the column from damaging the detector.

Carrier gas *helium for chromatography R.*

Flow rate 1.0 mL/min.

Split ratio 1:50.

Static head-space conditions that may be used:
- *equilibration temperature*: 80 °C for plasticised poly(vinyl chloride); 120 °C for cyclo-olefin polymers and copolymers, and polyurethane; 160 °C for silicone;
- *equilibration time*: 60 min;
- *transfer-line temperature*: 130 °C;
- *pressurisation time*: 0.5 min;
- *injection time*: 3 min;
- *shaking mode*: high agitation.

Temperature:

		Time (min)	Temperature (°C)
Column		0 - 2	100
		2 - 8.25	100 → 225
		8.25 - 13.25	225
Injection port			160
Detector:	transfer line		260
	source		230
	analyser		150

Detection Mass spectrometer; the following settings have been found to be suitable:
- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- *acquisition system*: single-ion monitoring (SIM) for ethylene oxide quantification and complete spectrum mode (*m/z* = 10-350) for ethylene oxide identification;
- mass spectrometer parameters for the fragmentometric mode (SIM) set as follows: *m/z* = 44 as ethylene oxide quantitation ion; *m/z* = 29 and *m/z* =15 as ethylene oxide qualification ions.

Injection 1 mL of the test sample and reference solutions (c), (d), (e), (f), (g), (h) and (j).

After injection of the test sample, remove the cap from the vial in a fume cupboard and purge the vial with dry nitrogen for 30 s. Close the vial with the cap and a new septum and repeat the heating and injection to exhaustion. Exhaustion is achieved when the amount of ethylene oxide extracted is less than 10 per cent of the 1st extraction or when no analytically significant increase in the cumulative residue levels is detected.

System suitability:
- *resolution*: minimum 1.5 between the peaks due to ethylene oxide and acetaldehyde in the chromatogram obtained with reference solution (j);
- *signal-to-noise ratio*: minimum 10 for the peak due to ethylene oxide in the chromatogram obtained with reference solution (h).

Verify the absence of peaks interfering with the peak due to ethylene oxide by carrying out the test on an unsterilised sample.

Calculation of content Establish a calibration curve with the mass of ethylene oxide in each reference solution as the abscissa and the corresponding peak areas as the ordinate.

For sets for transfusion, the total amount of ethylene oxide is calculated using the following formula:

$$EO = \sum_{i=1}^{n} (mi \times Ci)/M$$

EO	=	total amount of ethylene oxide, in ppm;
mi	=	mass of each plastic part of the set for transfusion, in grams;
Ci	=	cumulative amount of ethylene oxide determined in the corresponding plastic part, in micrograms per gram;
M	=	mass of the set for transfusion, in grams.

Limit If the label states that ethylene oxide has been used for sterilisation:
- *total (sum of amounts of ethylene oxide quantified in each plastic part of the set for transfusion)*: maximum 10 ppm.

Extraneous particles

Fill the set via the normal inlet with a 0.1 g/L solution of *sodium laurilsulfate R*, previously filtered through a sintered-glass filter (16) (*2.1.2*) and heated to 37 °C. Collect the

liquid via the normal outlet. When examined under suitable conditions of visibility, the liquid is clear and practically free from visible particles and filaments (it is assumed that particles and filaments with a diameter equal to or greater than 50 µm are visible to the naked eye).

Flow rate
Pass through a complete set with the flow regulator fully open 50 mL of a solution having a viscosity of 3 mPa·s (3 cP) (for example a 33 g/L solution of *macrogol 4000 R* at 20 °C) under a static head of 1 m. The time required for passage of 50 mL of the solution is not greater than 90 s.

Resistance to pressure
Make tight the extremities of the set and any air-inlet device. Connect the set to a compressed air outlet fitted with a pressure regulator. Immerse the set in a tank of water at 20-23 °C. Apply progressively an excess pressure of 100 kPa and maintain for 1 min. No air bubble escapes from the set.

Transparency
Use as reference suspension the primary opalescent suspension (*2.2.1*) diluted 8-fold for sets having tubing with an external diameter less than 5 mm and diluted 16-fold for sets having tubing with an external diameter of 5 mm or greater. Circulate the reference suspension through the set and compare with a set from the same batch filled with *water R*. The opalescence and presence of bubbles are discernible.

Residue on evaporation
Evaporate 50.0 mL of solution S to dryness on a water-bath and dry to constant mass in an oven at 100-105 °C. Carry out a blank test using 50.0 mL of *water R*. The residue obtained with solution S weighs not more than 1.5 mg, taking into account the blank test.

Sterility (*2.6.1*)
The sets comply with the test for sterility. If the sets are stated to be sterile only internally, pass 50 mL of buffered sodium chloride-peptone solution pH 7.0 (*2.6.12*) through the set and use the solution to carry out the test by the membrane filtration method.

If the sets are stated to be sterile both internally and externally, open the package with the necessary aseptic precautions and:
- for the direct inoculation method, place the set or its components in a suitable container containing a sufficient quantity of the culture medium to ensure complete immersion;
- for the membrane filtration method, place the set or its components in a suitable container containing a sufficient quantity of buffered sodium chloride-peptone solution pH 7.0 (*2.6.12*) to allow total rinsing for 10 min.

Pyrogens (*2.6.8*)
Connect together 5 sets and pass through the assembly, at a flow rate not exceeding 10 mL/min, 250 mL of a sterile, pyrogen-free, 9 g/L solution of *sodium chloride R*. Collect the solution aseptically in a pyrogen-free container. The solution complies with the test for pyrogens. Inject per kilogram of the rabbit's mass 10 mL of the solution.

LABELLING
The label states, where applicable, that the set has been sterilised using ethylene oxide.

G. Sterile Single-use Plastic Syringes

(Ph. Eur. method 3.3.8)

This general chapter is published for information.

DEFINITION
Sterile single-use plastic syringes are medical devices intended for immediate use for the administration of injectable preparations. They are supplied sterile and bacterial endotoxin-free and are not to be re-sterilised or re-used. They consist of a syringe barrel and a piston that may have an elastomer sealing ring; they may be fitted with a needle that may be non-detachable. Each syringe is presented with individual protection for maintaining sterility.

The barrel of the syringe is sufficiently transparent to permit dosages to be read without difficulty and allow air bubbles and foreign particles to be discerned.

The plastics and elastomer materials of which the barrel and piston are made comply with appropriate specifications or with requirements of the competent authority. The most commonly used materials are polypropylene and polyethylene. The syringes comply with current standards regarding dimensions and performance.

Silicone oil (*3.1.8*) may be applied to the internal wall of the barrel, in which case there remains no excess capable of contaminating the contents at the time of use. The inks, glues and adhesives for the marking on the syringe or on the package and, where necessary, the assembly of the syringe and its package, do not migrate across the walls.

TESTS

Solution S
Prepare the solution in a manner that avoids contamination by foreign particles. Using a sufficient number of syringes to produce 50 mL of solution, fill the syringes to their nominal volume with *water R* and maintain at 37 °C for 24 h. Combine the contents of the syringes in a suitable borosilicate-glass container.

Appearance of solution
Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*) and is practically free from foreign solid particles.

Acidity or alkalinity
To 20 mL of solution S add 0.1 mL of *bromothymol blue solution R1*. Not more than 0.3 mL of *0.01 M sodium hydroxide* or *0.01 M hydrochloric acid* is required to change the colour of the indicator.

Absorbance (*2.2.25*)
Maximum 0.40, determined between wavelengths of 220 nm and 360 nm on solution S.

Ethylene oxide
Head-space gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*). *Prepare the reference solutions immediately before use.*

Test sample Crush the sample into fine particles. Weigh 0.10-3.00 g of the sample, depending on the amount of ethylene oxide residue expected, into a 20 mL injection vial and close the vial. For low ethylene-oxide-releasing plastic materials (e.g. cyclo-olefin polymers and copolymers), heat the vial in an oven at 120 °C for at least 15 h (pre-thermal extraction step) before the 1st injection.

Reference solution (a) Dilute 1.0 mL of *ethylene oxide stock solution R1* to 50.0 mL with *anhydrous ethanol R* (1000 µg of ethylene oxide per millilitre). *If the solution is prepared using commercial ethylene oxide standard from a previously opened container, it should be noted that some ethylene oxide may have been lost owing to its high volatility.*

Reference solution (b) Dilute 10 mL of reference solution (a) to 20 mL with *anhydrous ethanol R* (500 µg of ethylene oxide per millilitre).

Reference solution (c) Dilute 8.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (400 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (c) into an injection vial and close immediately.

Reference solution (d) Dilute 6.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (300 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (d) into an injection vial and close immediately.

Reference solution (e) Dilute 4.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (200 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (e) into an injection vial and close immediately.

Reference solution (f) Dilute 2.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (100 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (f) into an injection vial and close immediately.

Reference solution (g) Dilute 1.0 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (50 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (g) into an injection vial and close immediately.

Reference solution (h) Dilute 0.5 mL of reference solution (a) to 20.0 mL with *anhydrous ethanol R* (25 µg of ethylene oxide per millilitre). Transfer 20 µL of reference solution (h) into an injection vial and close immediately.

Reference solution (i) Dilute 100 mg of *acetaldehyde R* to 100 mL with *anhydrous ethanol R* (1000 µg of acetaldehyde per millilitre).

Reference solution (j) Transfer 10 µL of reference solution (i) and 20 µL of reference solution (b) into an injection vial, mix and close immediately.

Column:
- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.32 mm;
- *stationary phase*: *porous silica for chromatography R* (film thickness 4 µm).

A particle trap may be used to prevent particles that are dislodged from the column from damaging the detector.

Carrier gas *helium for chromatography R.*

Flow rate 1.0 mL/min.

Split ratio 1:50.

Static head-space conditions that may be used:
- *equilibration temperature*: 80 °C for plasticised poly(vinyl chloride); 120 °C for cyclo-olefin polymers and copolymers, and polyurethane; 160 °C for silicone;
- *equilibration time*: 60 min;
- *transfer-line temperature*: 130 °C;
- *pressurisation time*: 0.5 min;
- *injection time*: 3 min;
- *shaking mode*: high agitation.

Temperature:

		Time (min)	Temperature (°C)
Column		0 - 2	100
		2 - 8.25	100 → 225
		8.25 - 13.25	225
Injection port			160
Detector:	transfer line		260
	source		230
	analyser		150

Detection Mass spectrometer; the following settings have been found to be suitable:
- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- *acquisition system*: single-ion monitoring (SIM) for ethylene oxide quantification and complete spectrum mode (*m/z* = 10-350) for ethylene oxide identification;
- mass spectrometer parameters for the fragmentometric mode (SIM) set as follows: *m/z* = 44 as ethylene oxide quantitation ion; *m/z* = 29 and *m/z* =15 as ethylene oxide qualification ions.

Injection 1 mL of the test sample and reference solutions (c), (d), (e), (f), (g), (h) and (j).

After injection of the test sample, remove the cap from the vial in a fume cupboard, and purge the vial with dry nitrogen for 30 s. Close the vial with the cap and a new septum and repeat the heating and injection to exhaustion. Exhaustion is achieved when the amount of ethylene oxide extracted is less than 10 per cent of the 1st extraction or when no analytically significant increase in the cumulative residue levels is detected.

System suitability:
- *resolution*: minimum 1.5 between the peaks due to ethylene oxide and acetaldehyde in the chromatogram obtained with reference solution (j);
- *signal-to-noise ratio*: minimum 10 for the peak due to ethylene oxide in the chromatogram obtained with reference solution (h).

Verify the absence of peaks interfering with the peak due to ethylene oxide by carrying out the test on an unsterilised sample.

Calculation of content Establish a calibration curve with the mass of ethylene oxide in each reference solution as the abscissa and the corresponding peak areas as the ordinate.

Limit If the label states that ethylene oxide has been used for sterilisation:
- *ethylene oxide*: maximum 10 ppm.

Silicone oil

Calculate the internal surface area of a syringe in square centimetres using the following expression:

$$2\sqrt{V \cdot \pi \cdot h}$$

V = nominal volume of the syringe, in cubic centimetres;
h = height of the graduation, in centimetres.

Take a sufficient number of syringes to give an internal surface area of 100 cm^2 to 200 cm^2. Aspirate into each syringe a volume of *methylene chloride R* equal to half the nominal volume and make up to the nominal volume with air. Rinse the internal surface corresponding to the nominal volume with the solvent by inverting the syringe 10 times in succession with the needle fitting closed by a finger covered by a plastic film inert to methylene chloride. Expel the extracts into a tared dish and repeat the operation. Evaporate the combined extracts to dryness on a water-bath. Dry at 100-105 °C for 1 h. The residue weighs not more than 0.25 mg per square centimetre of internal surface area.

Examine the residue by infrared absorption spectrophotometry (*2.2.24*).

Comparison *silicone oil CRS.*

Reducing substances

To 20.0 mL of solution S add 1 mL of *dilute sulfuric acid R* and 20.0 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g

of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate* using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration using 20.0 mL of *water R*. The difference between the 2 titration volumes is not greater than 3.0 mL.

Transparency
Fill a syringe with *water R* (blank) and fill another with a 10-fold dilution of primary opalescent suspension (*2.2.1*). Use primary opalescent suspension that has been allowed to stand at 20 ± 2 °C for 24 h before use. Compare with the naked eye in diffused light against a dark background. The opalescence of the suspension is detectable when compared with the blank.

Sterility (*2.6.1*)
Syringes stated to be sterile comply with the test for sterility carried out as follows Using aseptic technique, open the package, withdraw the syringe, separate the components and place each in a suitable container containing sufficient culture media to cover the part completely. Use both the recommended media (*2.6.1*).

Syringes stated to be sterile only internally comply with the test for sterility carried out as follows Use 50 mL of inoculation medium for each test syringe. Using aseptic technique, remove the needle protector and submerge the needle in the culture medium. Flush the syringe 5 times by withdrawing the plunger to its fullest extent.

Bacterial endotoxins (*2.6.14*)
Less than 0.5 IU/mL, determined on 10 syringes filled with an extraction volume of 40 mL of water for BET, unless otherwise justified and authorised.

LABELLING
The label states, where applicable, that the syringe has been sterilised using ethylene oxide.

Appendix XX

Materials Used for the Manufacture of Containers

(Ph. Eur. method 3.1)

The materials described in this chapter are used for the manufacture of containers for pharmaceutical use. Their use may also be considered for the manufacture of part or all of objects used for medico-surgical purposes.

Materials and polymers other than those described in the Pharmacopoeia may be used subject to approval in each case by the competent authority responsible for the licensing for sale of the preparation in the container.

Transmissible spongiform encephalopathies (*5.2.8*)
A risk assessment of the product with respect to transmissible spongiform encephalopathies is carried out, and suitable measures are taken to minimise any such risk.

Materials for Containers for Human Blood and Blood Components

(Ph. Eur. method 3.3.1)

This general chapter is published for information.

NOTE: for materials based on plasticised poly(vinyl chloride) for containers for aqueous solutions for intravenous infusion, see text 3.1.14.

Plastic containers for the collection, storage, processing and administration of blood and its components may be manufactured from one or more polymers, if necessary with certain additives.

If all or part of the container consists of a material described in a text of the Pharmacopoeia, the quality of the material is controlled by the methods indicated in that text. (See *3.3.2. Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components)*

In normal conditions of use the materials and containers made from such materials do not release monomers, or other substances, in amounts likely to be harmful nor do they lead to any abnormal modifications of the blood or blood components.

1. Materials Based on Plasticised Poly(vinyl chloride) for Containers for Human Blood and Blood Components

(Ph. Eur. method 3.3.2)

This general chapter is published for information.

DEFINITION
Materials based on plasticised poly(vinyl chloride) contain not less than 55 per cent of poly(vinyl chloride) and contain various additives, in addition to the high-molecular-mass polymer obtained by polymerisation of vinyl chloride.

Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components are defined by the nature and the proportions of the substances used in their manufacture.

PRODUCTION
Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods that guarantee a residual vinyl chloride content of less than 1 ppm.

Vinyl chloride

Head-space gas chromatography (*2.2.28*).

Internal standard solution Using a microsyringe, inject 10 µL of *ether R* into 20.0 mL of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution 1000-fold with *dimethylacetamide R*.

Test solution Place 1.000 g of the material to be examined in a 50 mL vial and add 10.0 mL of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution *Prepare in a fume cupboard.* Place 50.0 mL of *dimethylacetamide R* in a 50 mL vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 mL polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 mL of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 mL to 25 mL. Inject the remaining 25 mL of vinyl chloride slowly into the vial shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µL of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution Vinyl chloride primary solution, *dimethylacetamide R* (1:3 *V/V*).

Reference solutions Place 10.0 mL of the internal standard solution in each of six 50 mL vials. Close the vials and secure the stoppers. Inject 1 µL, 2 µL, 3 µL, 5 µL and 10 µL, respectively, of the vinyl chloride standard solution into 5 of the vials. The 6 solutions thus obtained contain, respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

Column:
- *material*: stainless steel;
- *size*: *l* = 3 m, Ø = 3 mm;
- *stationary phase*: *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearamide R* and 5 per cent *m/m* of *macrogol 400 R*.

Carrier gas *nitrogen for chromatography R*.

Flow rate 30 mL/min.

Temperature:
- *column*: 45 °C;
- *injection port*: 100 °C;
- *detector*: 150 °C.

Detection Flame ionisation.

Injection 1 mL.

Limit:
- *vinyl chloride*: maximum 1 ppm.

Additives

Depending on the intended use of the polymers, they contain additives to optimise their processing or their chemical, physical and mechanical properties. Unless otherwise justified and authorised, these additives are chosen from the following list, which specifies for each substance the maximum permitted content:
- di(2-ethylhexyl)phthalate (plastic additive 01): maximum 40 per cent;
- zinc octanoate (zinc 2-ethylhexanoate) (plastic additive 02): maximum 1 per cent;
- calcium stearate or zinc stearate: maximum 1 per cent or 1 per cent of a mixture of the two;
- *N,N'*-diacylethylenediamines (plastic additive 03): maximum 1 per cent;
- one of the following epoxidised oils: maximum 10 per cent or 10 per cent of a mixture of the two:
  - epoxidised soya oil (plastic additive 04), of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6;
  - epoxidised linseed oil (plastic additive 05), of which the oxiran oxygen content is not greater than 10 per cent and the iodine value is not greater than 7;
- cyclohexane 1,2-dicarboxylic acid, diisononyl ester (plastic additive 24): maximum 45 per cent;
- butyryl tri-*n*-hexyl citrate (plastic additive 25): maximum 45 per cent;
- tris(2-ethylhexyl) trimellitate (plastic additive 26): maximum 45 per cent;
- bis(2-ethylhexyl) terephthalate (plastic additive 27): maximum 45 per cent.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

Blood and blood components have different requirements, for example with respect to gas exchange, storage temperature and the mechanical properties of the containers. In addition, the stability and the quality of blood or blood components stored in containers can be influenced by the plasticisers/additives present in the materials used in the composition of the containers. To ensure the stability of blood and blood components during their manufacture and storage, the materials from which the containers are composed must be carefully selected according to the intended use.

CHARACTERS

Almost colourless or pale yellow powder, beads, granules or, after transformation, translucent sheets of varying thickness, with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, cut the samples of the material to be examined into pieces where the maximum size of a side is 1 cm.

To 2.0 g of the material to be examined add 200 mL of *peroxide-free ether R* and heat under a reflux condenser for 8 h. Separate the residue (residue B) and the solution (solution A) by filtration.

Evaporate solution A to dryness under reduced pressure in a water-bath at 30 °C. Dissolve the residue in 10 mL of *toluene R* (solution A1). Dissolve residue B in 60 mL of *ethylene chloride R*, heating on a water-bath under a reflux condenser. Filter. Add the solution obtained dropwise and with vigorous shaking to 600 mL of *heptane R* heated almost to boiling. Separate the coagulum (coagulum B1) and the organic solution by hot filtration. Allow the latter to cool; separate the precipitate that forms (precipitate B2) and filter through a tared sintered-glass filter (40) (*2.1.2*).

A. Infrared absorption spectrophotometry (*2.2.24*).

Preparation Dissolve coagulum B1 in 30 mL of *tetrahydrofuran R* and add, in small volumes with shaking, 40 mL of *anhydrous ethanol R*; separate the precipitate (precipitate B3) by filtration and dry *in vacuo* at a temperature not exceeding 50 °C over *diphosphorus*

pentoxide R; dissolve a few milligrams of precipitate B3 in 1 mL of *tetrahydrofuran R*, place a few drops of the solution obtained on a sodium chloride plate and evaporate to dryness in an oven at 100-105 °C.

Comparison *poly(vinyl chloride) CRS.*

B. Plastic additives 01, 24, 25, 26 and 27 (see Tests).

TESTS

If necessary, cut the samples of the material to be examined into pieces where the maximum size of a side is 1 cm.

Solution S1

Place 5.0 g of the material to be examined in a combustion flask. Add 30 mL of *sulfuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 mL of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 mL of *strong hydrogen peroxide solution R*; repeat by alternating evaporation and addition of hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 mL. Cool and dilute to 50.0 mL with *water R*.

Solution S2

Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 mL of *water R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool, decant the solution and dilute to 500 mL with *water R*.

Appearance of solution S2

Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity

To 100 mL of solution S2 add 0.15 mL of *BRP indicator solution R*. Not more than 1.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue.

To 100 mL of solution S2 add 0.2 mL of *methyl orange solution R*. Not more than 1.0 mL of *0.01 M hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*)

Evaporate 100.0 mL of solution S2 to dryness. Dissolve the residue in 5.0 mL of *hexane R*. From 250 nm to 310 nm the absorbance is not greater than 0.25.

Reducing substances

Carry out the test within 4 h of preparation of solution S2 To 20.0 mL of solution S2 add 1 mL of *dilute sulfuric acid R* and 20.0 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration using 20 mL of *water R*. The difference between the 2 titration volumes is not more than 2.0 mL.

Primary aromatic amines

Maximum 20 ppm.

To 2.5 mL of solution A1 obtained during the identification, add 6 mL of *water R* and 4 mL of *0.1 M hydrochloric acid*. Shake vigorously and discard the upper layer. To the aqueous layer add 0.4 mL of a freshly prepared 10 g/L solution of *sodium nitrite R*. Mix and allow to stand for 1 min. Add 0.8 mL of a 25 g/L solution of *ammonium sulfamate R*, allow to stand for 1 min and add 2 mL of a 5 g/L solution of *naphthylethylenediamine dihydrochloride R*. After 30 min, any colour in the solution is not more intense than that in a standard prepared at the same time and in the same manner, replacing the aqueous layer with a mixture of 1 mL of a 0.01 g/L solution of *naphthylamine R* in *0.1 M hydrochloric acid*, 5 mL of *water R* and 4 mL of *0.1 M hydrochloric acid*.

Plastic additives 01, 24, 25, 26 and 27

Gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*).

Internal standard solution S3 1 mg/mL solution of *di-n-octyl phthalate R* in *tetrahydrofuran for chromatography R*.

Internal standard solution S4 5 µg/mL solution of *di-n-octyl phthalate R* in *anhydrous ethanol R*.

Test solution Cut 0.2 g of the material to be examined into pieces about 0.5 cm in length. Dissolve the pieces in 12.5 mL of internal standard solution S3 using a polytetrafluoroethylene magnetic stirring bar. Complete dissolution of the material to be examined is obtained after stirring for about 20-30 min. The poly(vinyl chloride) is precipitated as a white powder by adding dropwise 37.5 mL of *anhydrous ethanol R*. Centrifuge, then dilute 1.0 mL of the supernatant to 50.0 mL with *anhydrous ethanol R*. The final concentration of the internal standard in the test solution is 5 µg/mL.

The stock solutions may be stored at 4 °C for up to 2 weeks.

Stock solution (a) Dissolve 20.0 mg of *plastic additive 01 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (b) Dissolve 20.0 mg of *plastic additive 24 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (c) Dissolve 20.0 mg of *plastic additive 25 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (d) Dissolve 20.0 mg of *plastic additive 26 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (e) Dissolve 20.0 mg of *plastic additive 27 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Reference solutions (a1)-(a5) Dilute stock solution (a) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 01 CRS*.

Reference solutions (b1)-(b5) Dilute stock solution (b) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 24 CRS*.

Reference solutions (c1)-(c5) Dilute stock solution (c) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 25 CRS*.

Reference solutions (d1)-(d5) Dilute stock solution (d) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 26 CRS*.

Reference solutions (e1)-(e5) Dilute stock solution (e) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 27 CRS*.

Column:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

Carrier gas *helium for chromatography R.*

Flow rate 1 mL/min.

Split ratio 1:20.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 3.3	100 → 200
	3.3 - 20	200 → 250
	20 - 22.5	250
	22.5 - 23	250 → 270
	23 - 25	270
	25 - 25.6	270 → 320
	25.6 - 30.6	320
Injection port		300

Detection Mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:
- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- *ion source temperature*: 230 °C;
- *acquisition system*: performed on full-scan (*m/z* = 40-350) and on single-ion monitoring (SIM) modes;
- *solvent delay*: 2.5 min;
- mass spectrometer parameters for the fragmentometric mode (SIM) set as follows:

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]
Plastic additive 01	149	167	279
Plastic additive 24	155	127	299
Plastic additive 25	71	213	315
Plastic additive 26	305	193	323
Plastic additive 27	261	149	167
DnOP (internal standard)	149	279	167

Injection 1 µL.

Relative retention With reference to di-*n*-octyl phthalate (retention time = about 22 min): plastic additive 01 = about 0.80; plastic additive 24 = about 0.95-1.09; plastic additive 27 = about 1.02; plastic additive 25 = about 1.14; plastic additive 26 = about 1.34.

The specificity of the detection is checked by monitoring 3 different ions for each substance using a mass spectrometer in SIM mode. Ion ratios are determined from the peak areas after the injection of a standard solution. The ratios in the table below are given for information.

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]	Ion ratio 2/1 (%)	Ion ratio 3/1 (%)
Plastic additive 01	149	167	279	50	30
Plastic additive 24	155	127	299	30	13
Plastic additive 25	71	213	315	45	20
Plastic additive 26	305	193	323	55	20
Plastic additive 27	261	149	167	130	85
DnOP (internal standard)	149	279	167	/	/

System suitability:
- *resolution*: if plastic additive 27 is tested, minimum 1.5 between the peaks due to the internal standard and plastic additive 27;
- *repeatability*: maximum relative standard deviation of 1.0 per cent for the retention time of the peak due to the plastic additive, determined on 6 injections of a reference solution of each plastic additive tested situated in the middle of the calibration range (e.g. 20 µg/mL);
- maximum relative standard deviation of 3.0 per cent for the ratio of the area of the peak due to the plastic additive to that due to the internal standard, determined on 6 injections of a reference solution of each plastic additive tested situated in the middle of the calibration range (e.g. 20 µg/mL).

From the calibration curve obtained with the reference solutions, calculate the percentage content of plastic additives in the material to be examined.

Limits:
- *plastic additive 01*: maximum 40 per cent;
- *plastic additive 24*: maximum 45 per cent;
- *plastic additive 25*: maximum 45 per cent;
- *plastic additive 26*: maximum 45 per cent;
- *plastic additive 27*: maximum 45 per cent.

Plastic additive 03

Wash precipitate B2 obtained during the identification and contained in the tared sintered-glass filter (40) (*2.1.2*) with *anhydrous ethanol R*. Dry to constant mass over *diphosphorus pentoxide R* and weigh the filter. The residue weighs not more than 20 mg.

Infrared absorption spectrophotometry (*2.2.24*).

Preparation The residue obtained above. When the amount of residue is insufficient to prepare a disc, record the spectrum of the residue placed between 2 plates transparent to infrared radiation or examine by attenuated total reflectance (ATR).

Comparison *plastic additive 03 CRS*.

Plastic additives 04 and 05

Thin-layer chromatography (*2.2.27*).

Reference solutions Prepare 10 mg/mL solutions of *plastic additive 04 CRS* and *plastic additive 05 CRS*, respectively, in *toluene R*.

Plate *TLC silica gel F_{254} plate R*.

Mobile phase *toluene R*.

Application 0.5 mL of solution A1 obtained during the identification, as a band 30 mm by 3 mm, and 5 µL of each reference solution.

Development Over 2/3 of the plate.

Drying In air.

Detection Expose the plate to iodine vapour for 5 min.

Examine the chromatogram and locate the zone corresponding to plastic additives 04 and 05 (R_F = 0). Remove the area of silica gel corresponding to this zone. Similarly remove a corresponding area of silica gel as a blank reference. Separately shake both samples for 15 min with 40 mL of *methanol R*. Filter, rinse with 2 quantities, each of 10 mL, of *methanol R*, add the rinsings to the filtrate and evaporate to dryness. The difference between the masses of both residues is not more than 10 mg.

Barium

Maximum 5 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Ignite 1.0 g of the material to be examined in a silica crucible. Take up the residue with 10 mL of *hydrochloric acid R* and evaporate to dryness on a water-bath. Take up the residue with 20 mL of *0.1 M hydrochloric acid*.

Reference solution A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid*.

Wavelength Use the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium

Maximum 0.6 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Evaporate 10 mL of solution S1 to dryness. Take up the residue using 5 mL of a 1 per cent *V/V* solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 mL with the same acid solution.

Reference solutions Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluting with a 1 per cent *V/V* solution of *hydrochloric acid R*.

Source Cadmium hollow-cathode lamp.

Wavelength 228.8 nm.

Atomisation device Air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Calcium

Maximum 0.07 per cent.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use the test solution prepared for the determination of barium.

Reference solution A solution containing 50.0 ppm of calcium prepared by dilution of *calcium standard solution (400 ppm Ca) R* with *0.1 M hydrochloric acid*.

Wavelength Use the emission of calcium at 315.89 nm, the spectral background being taken at 315.60 nm.

Verify the absence of calcium in the hydrochloric acid used.

Tin

Maximum 20 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Dilute solution S1 10-fold with *water R* immediately before use.

Reference solution Introduce 2 mL of *tin standard solution (5 ppm Sn) R* into a 50 mL flask containing 5 mL of a 20 per cent *V/V* solution of *sulfuric acid R* and dilute to 50 mL with *water R* immediately before use.

Wavelength Use the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the sulfuric acid used.

Zinc

Maximum 0.2 per cent.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Dilute solution S1 100-fold with *0.1 M hydrochloric acid*.

Reference solutions Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluting with *0.1 M hydrochloric acid*.

Source Zinc hollow-cathode lamp.

Wavelength 213.9 nm.

Atomisation device Air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Heavy metals (*2.4.8*)

Maximum 50 ppm.

To 10 mL of solution S1 add 0.5 mL of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 mL with *water R*. 12 mL of the solution complies with test A. Prepare the reference solution using *lead standard solution (2 ppm Pb) R*.

Water extractable substances

Maximum 0.3 per cent.

Evaporate 50 mL of solution S2 to dryness on a water-bath and dry in an oven at 100-105 °C to constant mass. Carry out a blank test with 50.0 mL of *water R*. The residue weighs not more than 7.5 mg taking into account the blank test.

ASSAY

Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg of the material to be examined. Absorb the combustion products in 20 mL of *1 M sodium hydroxide*. To the solution obtained add 2.5 mL of *nitric acid R*. Titrate with *0.1 M silver nitrate*, determining the end-point potentiometrically (*2.2.20*). Carry out a blank titration.

1 mL of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

Additional tests for sterile plastic containers for human blood and blood components are described in chapter 3.3. Containers for human blood and blood components, and materials used in their manufacture; transfusion sets and materials used in their manufacture; syringes and relevant subsections.

An additional test for the absorbance of an anticoagulant solution is described in general chapter 3.3.6. Sterile containers of plasticised poly(vinyl chloride) for human blood containing anticoagulant solution.

2. Materials Based on Plasticised Poly(vinyl chloride) for Tubing Used In Sets for the Transfusion of Blood and Blood Components

(Ph. Eur. method 3.3.3)

This general chapter is published for information.

DEFINITION

Materials based on plasticised poly(vinyl chloride) contain not less than 55 per cent of poly(vinyl chloride) and contain various additives, in addition to the high-molecular-mass polymer obtained by polymerisation of vinyl chloride.

Materials based on plasticised poly(vinyl chloride) for tubing used in sets for the transfusion of blood and blood components are defined by the nature and the proportions of the substances used in their manufacture.

Connecting ports are also to be considered as tubing.

PRODUCTION

Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods that guarantee a residual vinyl chloride content of less than 1 ppm.

Vinyl chloride

Head-space gas chromatography (*2.2.28*).

Internal standard solution Using a microsyringe, inject 10 µL of *ether R* into 20.0 mL of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution 1000-fold with *dimethylacetamide R*.

Test solution Place 1.000 g of the material to be examined in a 50 mL vial and add 10.0 mL of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution *Prepare in a fume cupboard.* Place 50.0 mL of *dimethylacetamide R* in a 50 mL vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 mL polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain

in contact with the syringe for about 3 min, empty the syringe and fill again with 50 mL of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 mL to 25 mL. Inject the remaining 25 mL of vinyl chloride slowly into the vial shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µL of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution Vinyl chloride primary solution, *dimethylacetamide R* (1:3 *V/V*).

Reference solutions Place 10.0 mL of the internal standard solution in each of six 50 mL vials. Close the vials and secure the stoppers. Inject 1 µL, 2 µL, 3 µL, 5 µL and 10 µL, respectively, of the vinyl chloride standard solution into 5 of the vials. The 6 solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

Column:
- *material*: stainless steel;
- *size*: *l* = 3 m, Ø = 3 mm;
- *stationary phase*: *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearamide R* and 5 per cent *m/m* of *macrogol 400 R*.

Carrier gas *nitrogen for chromatography R*.

Flow rate 30 mL/min.

Temperature:
- *column*: 45 °C;
- *injection port*: 100 °C;
- *detector*: 150 °C.

Detection Flame ionisation.

Injection 1 mL.

Limit:
- *vinyl chloride*: maximum 1 ppm.

Additives

Depending on the intended use of the polymers, they contain additives to optimise their processing or their chemical, physical and mechanical properties. Unless otherwise justified and authorised, these additives are chosen from the following list, which specifies for each substance the maximum permitted content:
- di(2-ethylhexyl)phthalate (plastic additive 01): maximum 40 per cent;
- cyclohexane 1,2-dicarboxylic acid, diisononyl ester (plastic additive 24): maximum 45 per cent;
- butyryl tri-*n*-hexyl citrate (plastic additive 25): maximum 45 per cent;
- tris(2-ethylhexyl) trimellitate (plastic additive 26): maximum 45 per cent;
- bis(2-ethylhexyl) terephthalate (plastic additive 27): maximum 45 per cent.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

Blood and blood components have different requirements, for example with respect to gas exchange, storage temperature and the mechanical properties of the tubing. In addition, the stability and the quality of blood or blood components during transfusion can be influenced by the plasticisers/additives present in the materials used in the composition of the tubing. To ensure the stability of blood and blood components during transfusion, the materials from which the tubing is composed must be carefully selected according to the intended use.

CHARACTERS

Almost colourless or pale-yellow material in the form of powder, beads, granules or, after transformation, tubes with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, cut the samples of the material to be examined into pieces where the maximum size of a side is 1 cm.

A. Infrared absorption spectrophotometry (*2.2.24*).

Preparation To 0.5 g of the material to be examined add 30 mL of *tetrahydrofuran R*. Heat with stirring on a water-bath in a fume cupboard for 10 min; the material dissolves completely. Add *methanol R* dropwise with stirring; a granular precipitate is formed. Filter the precipitate and dry at 60 °C. Examine the precipitate by infrared absorption spectrophotometry (*2.2.24*). Dissolve 50 mg in 2 mL of *tetrahydrofuran R* and pour on a glass slide. Dry in an oven at 80 °C, remove the film and fix on a suitable mount. Examine by infrared absorption spectrophotometry (*2.2.24*).

Comparison *poly(vinyl chloride) CRS*.

B. Plastic additives 01, 24, 25, 26 and 27 (see Tests).

TESTS

If necessary, cut the samples of the material to be examined into pieces where the maximum size of a side is 1 cm.

Solution S1

Place 5.0 g of the material to be examined in a combustion flask. Add 30 mL of *sulfuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 mL of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 mL of *strong hydrogen peroxide solution R*; repeat by alternating evaporation and addition of hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 mL. Cool and dilute to 50.0 mL with *water R*.

Solution S2

Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 mL of *water R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool. Decant the solution and dilute to 500 mL with *water R*.

Appearance of solution S2

Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Plastic additives 01, 24, 25, 26 and 27

Gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*).

Internal standard solution S3 1 mg/mL solution of *di-n-octyl phthalate R* in *tetrahydrofuran for chromatography R*.

Internal standard solution S4 5 µg/mL solution of *di-n-octyl phthalate R* in *anhydrous ethanol R*.

Test solution Cut 0.2 g of the material to be examined into pieces about 0.5 cm in length. Dissolve the pieces in 12.5 mL of internal standard solution S3 using a polytetrafluoroethylene magnetic stirring bar. Complete dissolution of the material to be examined is obtained after stirring for about 20-30 min. The poly(vinyl chloride) is precipitated as a white powder by adding dropwise 37.5 mL of *anhydrous ethanol R*. Centrifuge, then dilute 1.0 mL of the supernatant to 50.0 mL with *anhydrous ethanol R*. The final

concentration of the internal standard in the test solution is 5 µg/mL.

The stock solutions may be stored at 4 °C for up to 2 weeks.

Stock solution (a) Dissolve 20.0 mg of *plastic additive 01 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (b) Dissolve 20.0 mg of *plastic additive 24 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (c) Dissolve 20.0 mg of *plastic additive 25 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (d) Dissolve 20.0 mg of *plastic additive 26 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Stock solution (e) Dissolve 20.0 mg of *plastic additive 27 CRS* in internal standard solution S4 and dilute to 20.0 mL with internal standard solution S4.

Reference solutions (a1)-(a5) Dilute stock solution (a) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 01 CRS*.

Reference solutions (b1)-(b5) Dilute stock solution (b) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 24 CRS*.

Reference solutions (c1)-(c5) Dilute stock solution (c) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 25 CRS*.

Reference solutions (d1)-(d5) Dilute stock solution (d) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 26 CRS*.

Reference solutions (e1)-(e5) Dilute stock solution (e) with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 27 CRS*.

Column:
- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

Carrier gas *helium for chromatography R*.

Flow rate 1 mL/min.

Split ratio 1:20.

Temperature:

	Time (min)	Temperature (°C)
Column	0 - 3.3	100 → 200
	3.3 - 20	200 → 250
	20 - 22.5	250
	22.5 - 23	250 → 270
	23 - 25	270
	25 - 25.6	270 → 320
	25.6 - 30.6	320
Injection port		300

Detection Mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:
- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- *ion source temperature*: 230 °C;
- *acquisition system*: performed on full-scan (*m/z* = 40-350) and on single-ion monitoring (SIM) modes;
- *solvent delay*: 2.5 min;
- mass spectrometer parameters for the fragmentometric mode (SIM) set as follows:

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]
Plastic additive 01	149	167	279
Plastic additive 24	155	127	299
Plastic additive 25	71	213	315
Plastic additive 26	305	193	323
Plastic additive 27	261	149	167
DnOP (internal standard)	149	279	167

Injection 1 µL.

Relative retention With reference to di-*n*-octyl phthalate (retention time = about 22 min): plastic additive 01 = about 0.80; plastic additive 24 = about 0.95-1,09; plastic additive 27 = about 1.02; plastic additive 25 = about 1.14; plastic additive 26 = about 1.34.

The specificity of the detection is checked by monitoring 3 different ions for each substance using a mass spectrometer in SIM mode. Ion ratios are determined from the peak areas after the injection of a standard solution. The ratios in the table below are given for information.

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]	Ion ratio 2/1 (%)	Ion ratio 3/1 (%)
Plastic additive 01	149	167	279	50	30
Plastic additive 24	155	127	299	30	13
Plastic additive 25	71	213	315	45	20
Plastic additive 26	305	193	323	55	20
Plastic additive 27	261	149	167	130	85
DnOP (internal standard)	149	279	167	/	/

System suitability:
- *resolution*: if plastic additive 27 is tested, minimum 1.5 between the peaks due to the internal standard and plastic additive 27;
- *repeatability*: maximum relative standard deviation of 1.0 per cent for the retention time of the peak due to the plastic additive, determined on 6 injections of a reference solution of each plastic additive tested situated in the middle of the calibration range (e.g. 20 µg/mL); maximum relative standard deviation of 3.0 per cent for the ratio of the area of the peak due to the plastic additive to that due to the internal standard, determined on 6 injections of a reference solution of each plastic additive tested situated in the middle of the calibration range (e.g. 20 µg/mL).

From the calibration curve obtained with the reference solutions, calculate the percentage content of plastic additives in the material to be examined.

Limits:
- *plastic additive 01*: maximum 40 per cent;
- *plastic additive 24*: maximum 45 per cent;
- *plastic additive 25*: maximum 45 per cent;
- *plastic additive 26*: maximum 45 per cent;
- *plastic additive 27*: maximum 45 per cent.

Barium

Maximum 5 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Ignite 1.0 g of the material to be examined in a silica crucible. Take up the residue with 10 mL of

hydrochloric acid R and evaporate to dryness on a water-bath. Take up the residue with 20 mL of *0.1 M hydrochloric acid.*

Reference solution A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid.*

Wavelength Use the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium

Maximum 0.6 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Evaporate 10.0 mL of solution S1 to dryness. Take up the residue using 5 mL of a 1 per cent *V/V* solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 mL with the same acid.

Reference solutions Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluting with a 1 per cent *V/V* solution of *hydrochloric acid R.*

Source Cadmium hollow-cathode lamp.

Wavelength 228.8 nm.

Atomisation device Air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Tin

Maximum 20 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Dilute solution S1 10-fold with *water R* immediately before use.

Reference solution Introduce 2 mL of *tin standard solution (5 ppm Sn) R* into a 50 mL flask containing 5 mL of a 20 per cent *V/V* solution of *sulfuric acid R* and dilute to 50 mL with *water R* immediately before use.

Wavelength Use the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the sulfuric acid used.

Heavy metals (*2.4.8*)

Maximum 50 ppm.

To 10 mL of solution S1 add 0.5 mL of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 mL with *water R.* 12 mL of the solution complies with test A. Prepare the reference solution using *lead standard solution (2 ppm Pb) R.*

ASSAY

To 0.500 g of the material to be examined add 30 mL of *tetrahydrofuran R* and heat with stirring on a water-bath in a fume cupboard for 10 min. The material dissolves completely. Add 60 mL of *methanol R* dropwise with stirring. A granular precipitate of poly(vinyl chloride) is formed. Allow to stand for a few minutes. Continue addition of *methanol R* until no further precipitation is observed. Transfer to a sintered-glass filter (40) (*2.1.2*), using 3 small quantities of *methanol R* to aid transfer and to wash the precipitate. Dry the filter and the precipitate to constant mass at 60 °C and weigh.

Additional tests for sterilised sets are described in general chapter 3.3.7. Sets for the transfusion of blood and blood components.

3. Materials Based on Non-plasticised Poly(Vinyl Chloride) for Containers for Non-injectable, Aqueous Solutions

(Ph. Eur. method 3.1.10)

DEFINITION

Materials based on non-plasticised poly(vinyl chloride) that comply with the following specifications are suitable for the manufacture of containers for non-injectable aqueous solutions. They may also be used for solid forms for oral administration and in some cases, subject to special studies on the compatibility of the container with its contents, these materials may be suitable for the preparation of containers for suppositories. They consist of 1 or more poly(vinyl chloride/vinyl acetate) or of a mixture of poly(vinyl chloride) and poly(vinyl acetate) or of poly(vinyl chloride).

The chlorine content expressed as poly(vinyl chloride) is not less than 80 per cent.

They may contain not more than 15 per cent of copolymers based on acrylic and/or methacrylic acids and/or their esters, and/or on styrene and/or butadiene.

PRODUCTION

Materials based on non-plasticised poly(vinyl chloride) are produced by polymerisation methods that guarantee a residual vinyl chloride content of less than 1 ppm.
The manufacturing process is validated to demonstrate that the product complies with the following test.

Vinyl chloride

Head-space gas chromatography (*2.2.28*).

Internal standard solution Using a microsyringe, inject 10 µL of *ether R* into 20.0 mL of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution 1000-fold with *dimethylacetamide R.*

Test solution Place 1.000 g of the material to be examined in a 50 mL vial and add 10.0 mL of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution *Prepare in a fume cupboard.* Place 50.0 mL of *dimethylacetamide R* in a 50 mL vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 mL polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 mL of gaseous *vinyl chloride R.* Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 mL to 25 mL. Inject these 25 mL of vinyl chloride slowly into the vial, shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µL of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution Vinyl chloride primary solution, *dimethylacetamide R* (1:3 *V/V*).

Reference solutions Place 10.0 mL of the internal standard solution in each of six 50 mL vials. Close the vials and secure the stoppers. Inject 1 µL, 2 µL, 3 µL, 5 µL and 10 µL, respectively, of the vinyl chloride standard solution into 5 of the vials. The 6 solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

Column:
— *material*: stainless steel;
— *size*: *l* = 3 m, Ø = 3 mm;
— *stationary phase*: *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearamide R* and 5 per cent *m/m* of *macrogol 400 R*.

Carrier gas *nitrogen for chromatography R*.

Flow rate 30 mL/min.

Temperature:
— *column*: 45 °C;
— *injection port*: 100 °C;
— *detector*: 150 °C.

Detection Flame ionisation.

Injection 1 mL of the head space.

Limit:
— *vinyl chloride*: maximum 1 ppm.

Additives

Depending on the intended use of the polymers, they may contain additives to optimise their processing or their chemical, physical and mechanical properties. These additives are chosen from the following list, which specifies for each substance the maximum allowable content:
— epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6: maximum 8 per cent;
— calcium salt or zinc salts of aliphatic fatty acids with more than 7 carbon atoms: maximum 1.5 per cent or maximum 1.5 per cent of their mixture;
— liquid paraffin: maximum 1.5 per cent;
— waxes: maximum 1.5 per cent;
— hydrogenated oils or esters of aliphatic fatty acids: maximum 2 per cent;
— macrogol esters: maximum 1.5 per cent;
— sorbitol: maximum 1.5 per cent;
— 2,4-dinonylphenyl phosphite, or di(4-nonylphenyl) phosphite or tris(nonylphenyl) phosphite: maximum 1 per cent.

They may contain one of the following groups of stabilisers (where isooctyl is, for example, 2-ethylhexyl):
— tin as di(isooctyl) 2,2′-[(dioctylstannylene)bis (thio)]diacetate containing about 27 per cent of tri (isooctyl) 2,2′,2″-[(monooctylstannylidyne)tris(thio)] triacetate: maximum 0.25 per cent;
— tin as a mixture containing not more than 76 per cent of di(isooctyl) 2,2′-[(dimethylstannylene)bis(thio)]diacetate and not more than 85 per cent of tri(isooctyl) 2,2′,2″-[(monomethylstannylidyne)tris(thio)]triacetate: maximum 0.25 per cent;
— 1-phenyleicosane-1,3-dione (benzoylstearoylmethane) or 2-(4-dodecylphenyl)indole or didodecyl 1,4-dihydropyridine-2,6-dimethyl-3,5-dicarboxylate: maximum 1 per cent or 1 per cent of a mixture of 2 of these.

Colouring materials may be added, provided that the safety of the material is demonstrated to the satisfaction of the competent authority. The material may be opacified with titanium dioxide.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Appearance

Powder, beads, granules, sheets of varying thicknesses or samples taken from finished objects.

Solubility

Practically insoluble in water, soluble in tetrahydrofuran, slightly soluble in methylene chloride, insoluble in anhydrous ethanol.

They burn with an orange-yellow flame edged with green, giving off thick black smoke.

IDENTIFICATION

Infrared absorption spectrophotometry (*2.2.24*).

Preparation Dissolve residue A (see Tests: solution S2) in 5 mL of *tetrahydrofuran R*. Apply a few drops of the solution to a sodium chloride plate and evaporate to dryness in an oven at 100-105 °C.

Absorption maxima (tolerance ± 5 cm^{-1}): at 2910 cm^{-1}, 1425 cm^{-1}, 1330 cm^{-1}, 1252 cm^{-1}, 958 cm^{-1} and 690 cm^{-1}.

The spectrum obtained is identical to that of the material selected for the type sample.

TESTS

If necessary, cut the samples of the material to be examined into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1

Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 mL of *water R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave for 121 ± 2 °C for 20 min. Allow to cool, decant the solution and make up to 500 mL with *water R*.

Solution S2

Dissolve 5.0 g of the material to be examined in 80 mL of *tetrahydrofuran R* and dilute to 100 mL with the same solvent. Filter if necessary (the solution may remain opalescent). To 20 mL of the solution add, dropwise and with gentle shaking, 70 mL of *ethanol (96 per cent) R*. Cool in ice for 1 h. Filter or centrifuge (residue A). Wash residue A with *ethanol (96 per cent) R*, add the washings to the filtrate or the centrifugation liquid and dilute to 100 mL with *ethanol (96 per cent) R*.

Solution S3

Place 5 g of the material to be examined in a borosilicate-glass flask with a ground-glass neck. Add 100 mL of *0.1 M hydrochloric acid* and boil under a reflux condenser for 1 h. Allow to cool and allow the solids to settle.

Appearance of solution S1

Solution S1 is not more opalescent than reference suspension II (*2.2.1*) and is colourless (*2.2.2, Method II*).

Absorbance of solution S1 (*2.2.25*)

Evaporate 100 mL of solution S1 to dryness. Dissolve the residue in 5 mL of *hexane R*. Filter if necessary through a filter previously rinsed with *hexane R*. At wavelengths from 250 nm to 310 nm, the absorbance of the filtrate is not greater than 0.25.

Absorbance of solution S2 (*2.2.25*)

Maximum 0.2 for tin-stabilised materials or 0.4 for other materials determined between wavelengths of 250 nm and 330 nm on solution S2.

Extractable barium

Maximum 2 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S3.

Reference solution A solution containing 0.1 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid.*

Wavelength Use the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Examined at 455.40 nm, the emission of the test solution is not greater than that of the reference solution.

Extractable cadmium
Maximum 0.6 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Solution S3.

Reference solution A solution containing 0.03 ppm of cadmium prepared by diluting *cadmium standard solution (0.1 per cent Cd) R* with *0.1 M hydrochloric acid.*

Verify the absence of cadmium in the hydrochloric acid used.

Examined at 228.8 nm, the absorbance of the test solution is not greater than that of the reference solution.

Tin-stabilised materials
Maximum 0.25 per cent of Sn.

Tin stock solution Dilute 81 mg of *plastic additive 23 GRS* to 100.0 mL with *tetrahydrofuran R.*

Tin standard solution Dilute 20 mL of the tin stock solution to 100.0 mL with *ethanol (96 per cent) R.*

To 0.10 mL of solution S2 in a test tube add 0.05 mL of *1 M hydrochloric acid,* 0.5 mL of *potassium iodide solution R* and 5 mL of *ethanol (96 per cent) R.* Mix thoroughly and wait for 5 min. Add 9 mL of *water R* and 0.1 mL of a 5 g/L solution of *sodium sulfite heptahydrate R* and mix thoroughly. Add 1.5 mL of *dithizone solution R* freshly diluted 100-fold with *methylene chloride R,* shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.1 mL of the tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution. The greenish-blue colour of dithizone solution turns pink in the presence of tin.

Non-tin stabilised materials
Maximum 25 ppm of Sn.

To 5 mL of solution S2 in a test tube add 0.05 mL of *1 M hydrochloric acid* and 0.5 mL of *potassium iodide solution R.* Mix thoroughly and wait for 5 min. Add 9 mL of *water R* and 0.1 mL of a 5 g/L solution of *sodium sulfite heptahydrate R* and mix thoroughly. If the solution obtained is not colourless, add the sodium sulfite solution in 0.05 mL fractions. Add 1.5 mL of *dithizone solution R* freshly diluted 100-fold with *methylene chloride R,* shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.05 mL of the tin standard solution (see test above).

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution.

Extractable heavy metals (*2.4.8*)
Maximum 20 ppm.

12 mL of solution S3 complies with test A. Prepare the reference solution using 10 mL of *lead standard solution (1 ppm Pb) R.*

Extractable zinc
Maximum 100 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Solution S3 diluted 10-fold with *water R.*

Reference solution A solution containing 0.50 ppm of zinc prepared by dilution of *zinc standard solution (5 mg/mL Zn) R* with *0.01 M hydrochloric acid.*

Verify the absence of zinc in the hydrochloric acid used.

Examined at 214.0 nm, the absorbance of the test solution is not greater than that of the reference solution.

Sulfated ash (*2.4.14*)
Maximum 1.0 per cent, determined on 1.0 g; maximum 4.0 per cent when the materials are opacified with titanium dioxide.

ASSAY
Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg of the material to be examined. Absorb the combustion products in 20 mL of *1 M sodium hydroxide.* To the solution obtained add 2.5 mL of *nitric acid R.* Titrate with *0.1 M silver nitrate,* determining the end-point potentiometrically (*2.2.20*). Carry out a blank titration.

1 mL of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

4. Materials based on Non-Plasticised Poly(Vinyl Chloride) for Containers for Solid Dosage Forms for Oral Administration

(Ph. Eur. method 3.1.11)

DEFINITION
Materials based on non-plasticised poly(vinyl chloride) for containers for solid dosage forms for oral administration are suitable for the manufacture of sheets or containers, and consist of 1 or more poly(vinyl chloride/vinyl acetate) or of a mixture of poly(vinyl chloride) and poly(vinyl acetate) or of poly(vinyl chloride).

The chlorine content expressed as poly(vinyl chloride) is not less than 80 per cent.

They may contain not more than 15 per cent of copolymers based on acrylic and/or methacrylic acids and/or their esters, and/or on styrene and/or butadiene.

PRODUCTION
Materials based on non-plasticised poly(vinyl chloride) are produced by polymerisation methods that guarantee a residual vinyl chloride content of less than 1 ppm.
The manufacturing process is validated to demonstrate that the product complies with the following test for vinyl chloride.

Vinyl chloride
Head-space gas chromatography (*2.2.28*).

Internal standard solution Using a microsyringe, inject 10 µL of *ether R* into 20.0 mL of *dimethylacetamide R,* immersing the tip of the needle in the solvent. Immediately before use, dilute the solution 1000-fold with *dimethylacetamide R.*

Test solution Place 1.000 g of the material to be examined in a 50 mL vial and add 10.0 mL of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution *Prepare in a fume cupboard.* Place 50.0 mL of *dimethylacetamide R* in a 50 mL vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 mL polyethylene or polypropylene syringe with gaseous *vinyl chloride R,* allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 mL of gaseous *vinyl chloride R.*

Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 mL to 25 mL. Inject the 25 mL of vinyl chloride slowly into the vial, shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µL of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution Vinyl chloride primary solution, *dimethylacetamide R* (1:3 *V/V*).

Reference solutions Place 10.0 mL of the internal standard solution in each of six 50 mL vials. Close the vials and secure the stoppers. Inject 1 µL, 2 µL, 3 µL, 5 µL and 10 µL, respectively, of the vinyl chloride standard solution into 5 of the vials. The 6 solutions thus obtained contain respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

Column:
- *material*: stainless steel;
- *size*: *l* = 3 m, Ø = 3 mm;
- *stationary phase*: *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearamide R* and 5 per cent *m/m* of *macrogol 400 R*.

Carrier gas *nitrogen for chromatography R*.

Flow rate 30 mL/min.

Temperature:
- *column*: 45 °C;
- *injection port*: 100 °C;
- *detector*: 150 °C.

Detection Flame ionisation.

Injection 1 mL of the head space.

Limit:
- *vinyl chloride*: maximum 1 ppm.

Additives

Depending on the intended use of the polymers, they may contain additives to optimise their processing or their chemical, physical and mechanical properties. These additives are chosen from the following list, which specifies for each substance the maximum allowable content:
- epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6 for tin-stabilised materials: maximum 2 per cent;
- epoxidised soya oil of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6 for non-tin-stabilised materials: maximum 3 per cent;
- calcium, magnesium or zinc salts of aliphatic fatty acids with more than 7 carbon atoms: maximum 1.5 per cent or maximum 1.5 per cent of their mixture;
- waxes: maximum 4 per cent;
- liquid paraffin: maximum 1.5 per cent;
- hydrogenated oils or esters of aliphatic fatty acids: maximum 2 per cent;
- the percentage sum of the 3 lubricants above: maximum 4 per cent;
- macrogol esters: maximum 1.5 per cent;
- sorbitol: maximum 1.5 per cent;
- 2,4-dinonylphenyl phosphite, or di(4-nonylphenyl) phosphite or tris(nonylphenyl) phosphite: maximum 1 per cent;
- calcium carbonate: maximum 1 per cent;
- silica: maximum 1 per cent.

They may contain one of the following groups of stabilisers (where isooctyl is, for example, 2-ethylhexyl):
- tin as di(isooctyl) 2,2′-[(dioctylstannylene)bis (thio)]diacetate containing about 27 per cent of tri (isooctyl) 2,2′2″-[(monooctylstannylidyne)tris(thio)] triacetate: maximum 0.25 per cent;
- tin as tri(isooctyl) 2,2′2″-[(monooctylstannylidyne)tris (thio)]triacetate: maximum 0.25 per cent;
- tin as a mixture containing not more than 76 per cent of di(isooctyl) 2,2′-[(dimethylstannylene)bis(thio)]diacetate and not more than 85 per cent of tri(isooctyl) 2,2′,2″-[(monomethylstannylidyne)tris(thio)]triacetate: maximum 0.25 per cent;
- 1-phenyleicosane-1,3-dione (benzoylstearoylmethane): maximum 1 per cent.

Colouring materials may be added, provided that the safety of the material is demonstrated to the satisfaction of the competent authority. The material may be opacified with titanium dioxide.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Appearance

Powder, beads, granules, sheets of varying thicknesses or samples taken from finished objects.

Solubility

Practically insoluble in water, soluble in tetrahydrofuran, slightly soluble in methylene chloride, practically insoluble in anhydrous ethanol.

They burn with an orange-yellow flame edged with green, giving off thick black smoke.

IDENTIFICATION

Infrared absorption spectrophotometry (*2.2.24*).

Preparation Dissolve residue A (see Tests: solution S2) in 5 mL of *tetrahydrofuran R*. Apply a few drops of the solution to a sodium chloride plate and evaporate to dryness in an oven at 100-105 °C.

Absorption maxima (tolerance ± 5 cm^{-1}): at 2910 cm^{-1}, 1425 cm^{-1}, 1330 cm^{-1}, 1252 cm^{-1}, 958 cm^{-1} and 690 cm^{-1}.

The spectrum obtained is identical to that of the material selected for the type sample.

TESTS

If necessary, cut the samples of the material to be examined into pieces with a maximum dimension on a side of not greater than 1 cm.

Solution S1

Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 mL of *water R* and cover the neck of the flask with a borosilicate glass beaker. Heat in an autoclave for 121 ± 2 °C for 20 min. Allow to cool, decant the solution and make up to 500 mL with *water R*.

Solution S2

Dissolve 5.0 g of the material to be examined in 80 mL of *tetrahydrofuran R* and dilute to 100 mL with the same solvent. Filter if necessary (the solution may remain opalescent). To 20 mL of the solution add, dropwise and with gentle shaking, 70 mL of *ethanol (96 per cent) R*. Cool in ice for 1 h. Filter or centrifuge (residue A). Wash residue A with *ethanol (96 per cent) R*, add the washings to the filtrate

or the centrifugation liquid and dilute to 100 mL with *ethanol (96 per cent) R*.

Solution S3
Place 5 g of the material to be examined in a borosilicate-glass flask with a ground-glass neck. Add 100 mL of *0.1 M hydrochloric acid* and boil under a reflux condenser for 1 h. Allow to cool and allow the solids to settle.

Appearance of solution S1
Solution S1 is not more opalescent than reference suspension II (*2.2.1*) and is colourless (*2.2.2, Method II*).

Absorbance of solution S1 (*2.2.25*)
Evaporate 100 mL of solution S1 to dryness. Dissolve the residue in 5 mL of *hexane R*. Filter if necessary through a filter previously rinsed with *hexane R*. At wavelengths from 250 nm to 310 nm, the absorbance of the filtrate is not greater than 0.3.

Absorbance of solution S2 (*2.2.25*)
Maximum 1.0, determined between wavelengths of 250 nm and 330 nm on solution S2 for material that does not contain 1-phenyleicosane-1,3-dione; maximum 0.4, determined between wavelengths of 250 nm and 330 nm on a 10-fold dilution of solution S2 in *ethanol (96 per cent) R* for material that contains 1-phenyleicosane-1,3-dione.

Tin-stabilised materials
Maximum 0.25 per cent of Sn.

Tin stock solution Dilute 81 mg of *plastic additive 23 CRS* to 100.0 mL with *tetrahydrofuran R*.

Tin standard solution Dilute 20 mL of the tin stock solution to 100.0 mL with *ethanol (96 per cent) R*.

To 0.10 mL of solution S2 in a test-tube add 0.05 mL of *1 M hydrochloric acid*, 0.5 mL of *potassium iodide solution R* and 5 mL of *ethanol (96 per cent) R*. Mix thoroughly and wait for 5 min. Add 9 mL of *water R* and 0.1 mL of a 5 g/L solution of *sodium sulfite heptahydrate R* and mix thoroughly. Add 1.5 mL of *dithizone solution R* freshly diluted 100-fold with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.1 mL of the tin standard solution.

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution. The greenish-blue colour of dithizone solution turns pink in the presence of tin.

Non-tin-stabilised materials
Maximum 25 ppm of Sn.

To 5 mL of solution S2 in a test-tube add 0.05 mL of *1 M hydrochloric acid* and 0.5 mL of *potassium iodide solution R*. Mix thoroughly and wait for 5 min. Add 9 mL of *water R* and 0.1 mL of a 5 g/L solution of *sodium sulfite heptahydrate R* and mix thoroughly. If the solution obtained is not colourless, add the sodium sulfite solution in 0.05 mL fractions. Add 1.5 mL of *dithizone solution R* freshly diluted 100-fold with *methylene chloride R*, shake for 15 s and allow to stand for 2 min. At the same time prepare a reference solution in the same manner using 0.05 mL of the tin standard solution (see test above).

Any violet colour in the lower layer obtained with solution S2 is not more intense than that obtained with the reference solution.

Extractable heavy metals (*2.4.8*)
Maximum 20 ppm.

12 mL of solution S3 complies with test A. Prepare the reference solution using 10 mL of *lead standard solution (1 ppm Pb) R*.

Extractable zinc
Maximum 100 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Solution S3 diluted 10-fold with *water R*.

Reference solution A solution containing 0.50 ppm of zinc prepared by dilution of *zinc standard solution (5 mg/mL Zn) R* with *0.01 M hydrochloric acid*.

Verify the absence of zinc in the hydrochloric acid used.

Examined at 214.0 nm, the absorbance of the test solution is not greater than that of the reference solution.

Sulfated ash (*2.4.14*)
Maximum 1.0 per cent, determined on 1.0 g; maximum 4.0 per cent when the materials are opacified with titanium dioxide.

ASSAY
Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg of the material to be examined. Absorb the combustion products in 20 mL of *1 M sodium hydroxide*. To the solution obtained add 2.5 mL of *nitric acid R*. Titrate with *0.1 M silver nitrate*, determining the end-point potentiometrically (*2.2.20*). Carry out a blank titration.

1 mL of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

5. Materials Based on Plasticised Poly(Vinyl Chloride) for Containers for Aqueous Solutions for Intravenous Infusion

(Ph. Eur. method 3.1.14)

DEFINITION
Materials based on plasticised poly(vinyl chloride) contain not less than 55 per cent of poly(vinyl chloride) and contain various additives, in addition to the high-molecular-mass polymer obtained by polymerisation of vinyl chloride.

Materials based on plasticised poly(vinyl chloride) for containers for aqueous solutions for intravenous infusion are defined by the nature and the proportions of the substances used in their manufacture.

PRODUCTION
Materials based on plasticised poly(vinyl chloride) are produced by polymerisation methods that guarantee a residual vinyl chloride content of less than 1 ppm.

Vinyl chloride
Head-space gas chromatography (*2.2.28*).

Internal standard solution Using a microsyringe, inject 10 µL of *ether R* into 20.0 mL of *dimethylacetamide R*, immersing the tip of the needle in the solvent. Immediately before use, dilute the solution 1000-fold with *dimethylacetamide R*.

Test solution Place 1.000 g of the material to be examined in a 50 mL vial and add 10.0 mL of the internal standard solution. Close the vial and secure the stopper. Shake, avoiding contact between the stopper and the liquid. Place the vial in a water-bath at 60 ± 1 °C for 2 h.

Vinyl chloride primary solution *Prepare in a fume cupboard.* Place 50.0 mL of *dimethylacetamide R* in a 50 mL vial, stopper the vial, secure the stopper and weigh to the nearest 0.1 mg. Fill a 50 mL polyethylene or polypropylene syringe with gaseous *vinyl chloride R*, allow the gas to remain in contact with the syringe for about 3 min, empty the syringe and fill again with 50 mL of gaseous *vinyl chloride R*. Fit a hypodermic needle to the syringe and reduce the volume of gas in the syringe from 50 mL to 25 mL. Inject the remaining 25 mL of vinyl chloride slowly into the vial

shaking gently and avoiding contact between the liquid and the needle. Weigh the vial again; the increase in mass is about 60 mg (1 µL of the solution thus obtained contains about 1.2 µg of vinyl chloride). Allow to stand for 2 h. Keep the primary solution in a refrigerator.

Vinyl chloride standard solution Vinyl chloride primary solution, *dimethylacetamide R* (1:3 *V/V*).

Reference solutions Place 10.0 mL of the internal standard solution in each of six 50 mL vials. Close the vials and secure the stoppers. Inject 1 µL, 2 µL, 3 µL, 5 µL and 10 µL, respectively, of the vinyl chloride standard solution into 5 of the vials. The 6 solutions thus obtained contain, respectively, 0 µg, about 0.3 µg, 0.6 µg, 0.9 µg, 1.5 µg and 3 µg of vinyl chloride. Shake, avoiding contact between the stopper and the liquid. Place the vials in a water-bath at 60 ± 1 °C for 2 h.

Column:
- *material*: stainless steel;
- *size*: *l* = 3 m, Ø = 3 mm;
- *stationary phase*: *silanised diatomaceous earth for gas chromatography R* impregnated with 5 per cent *m/m* of *dimethylstearamide R* and 5 per cent *m/m* of *macrogol 400 R*.

Carrier gas *nitrogen for chromatography R*.

Flow rate 30 mL/min.

Temperature:
- *column*: 45 °C;
- *injection port*: 100 °C;
- *detector*: 150 °C.

Detection Flame ionisation.

Injection 1 mL of the head-space.

Limit:
- *vinyl chloride*: maximum 1 ppm.

Additives

Depending on the intended use of the polymers, they contain additives to optimise their processing or their chemical, physical and mechanical properties. Unless otherwise justified and authorised, these additives are chosen from the following list, which specifies for each substance the maximum permitted content:
- di(2-ethylhexyl) phthalate (plastic additive 01): maximum 40 per cent;
- zinc octanoate (zinc 2-ethylhexanoate) (plastic additive 02): maximum 1 per cent;
- calcium stearate or zinc stearate: maximum 1 per cent or 1 per cent of a mixture of the two;
- *N,N'*-diacylethylenediamines (plastic additive 03): maximum 1 per cent;
- maximum 10 per cent of one of the following epoxidised oils or 10 per cent of a mixture of the two:
  - epoxidised soya oil (plastic additive 04) of which the oxiran oxygen content is 6 per cent to 8 per cent and the iodine value is not greater than 6;
  - epoxidised linseed oil (plastic additive 05) of which the oxiran oxygen content is not greater than 10 per cent and the iodine value is not greater than 7.

When colouring materials are added, ultramarine blue (plastic additive 06) is used. Other colouring materials may be added, provided that the safety of the material is demonstrated to the satisfaction of the competent authority.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample is satisfactory for each production batch.

CHARACTERS

Colourless, slightly blue or pale yellow powder, beads, granules or, after transformation, translucent sheets of varying thickness, with a slight odour. On combustion it gives off dense, black smoke.

IDENTIFICATION

If necessary, cut the samples of the material to be examined into pieces where the maximum size of a side is 1 cm.

To 2.0 g of the material to be examined add 200 mL of *peroxide-free ether R* and heat under a reflux condenser for 8 h. Separate the residue (residue B) and the solution (solution A) by filtration.

Evaporate solution A to dryness under reduced pressure in a water-bath at 30 °C. Dissolve residue in 10 mL of *toluene R* (solution A1). Dissolve residue B in 60 mL of *ethylene chloride R*, heating on a water-bath under a reflux condenser. Filter. Add the obtained solution dropwise and with vigorous shaking to 600 mL of *heptane R* heated almost to boiling. Separate by hot filtration the coagulum (coagulum B1) and the organic solution. Allow the latter to cool; separate the precipitate that forms (precipitate B2) and filter through a tared sintered-glass filter (40) (*2.1.2*).

A. Infrared absorption spectrophotometry (*2.2.24*).

Preparation Dissolve coagulum B1 in 30 mL of *tetrahydrofuran R* and add, in small volumes with shaking, 40 mL of *anhydrous ethanol R*; separate the precipitate (precipitate B3) by filtration and dry *in vacuo* at a temperature not exceeding 50 °C over *diphosphorus pentoxide R*; dissolve a few milligrams of precipitate B3 in 1 mL of *tetrahydrofuran R*, place a few drops of the solution obtained on a sodium chloride plate and evaporate to dryness in an oven at 100-105 °C.

Comparison *poly(vinyl chloride) CRS*.

B. Plastic additive 01 (see Tests).

TESTS

If necessary, cut the samples of the material to be examined into pieces where the maximum size of a side is 1 cm.

Solution S1

Place 5.0 g of the material to be examined in a combustion flask. Add 30 mL of *sulfuric acid R* and heat until a black, syrupy mass is obtained. Cool and add carefully 10 mL of *strong hydrogen peroxide solution R*. Heat gently. Allow to cool and add 1 mL of *strong hydrogen peroxide solution R*; repeat by alternating evaporation and addition of strong hydrogen peroxide solution until a colourless liquid is obtained. Reduce the volume to about 10 mL. Cool and dilute to 50.0 mL with *water R*.

Solution S2

Place 25 g of the material to be examined in a borosilicate-glass flask. Add 500 mL of *water R* and cover the neck of the flask with a borosilicate-glass beaker. Heat in an autoclave at 121 ± 2 °C for 20 min. Allow to cool, decant the solution and make up to 500 mL with *water R*.

Appearance of solution S2

Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity

To 100 mL of solution S2 add 0.15 mL of *BRP indicator solution R*. Not more than 1.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue.

To 100 mL of solution S2 add 0.2 mL of *methyl orange solution R*. Not more than 1.0 mL of *0.01 M hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*)
Evaporate 100.0 mL of solution S2 to dryness. Dissolve the residue in 5.0 mL of *hexane R*. From 250 nm to 310 nm the absorbance is not greater than 0.25.

Reducing substances
Carry out the test within 4 h of preparation of solution S2 To 20.0 mL of solution S2 add 1 mL of *dilute sulfuric acid R* and 20.0 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration using 20 mL of *water R*. The difference between the 2 titration volumes is not greater than 2.0 mL.

Primary aromatic amines
Maximum 20 ppm.

To 2.5 mL of solution A1 obtained during the identification, add 6 mL of *water R* and 4 mL of *0.1 M hydrochloric acid*. Shake vigorously and discard the upper layer. To the aqueous layer add 0.4 mL of a freshly prepared 10 g/L solution of *sodium nitrite R*. Mix and allow to stand for 1 min. Add 0.8 mL of a 25 g/L solution of *ammonium sulfamate R*, allow to stand for 1 min and add 2 mL of a 5 g/L solution of *naphthylethylenediamine dihydrochloride R*. After 30 min, any colour in the solution is not more intense than that in a standard prepared at the same time and in the same manner, replacing the aqueous layer with a mixture of 1 mL of a 0.01 g/L solution of *naphthylamine R* in *0.1 M hydrochloric acid*, 5 mL of *water R* and 4 mL of *0.1 M hydrochloric acid*.

Plastic additive 01
Gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*).

Internal standard solution S3 1 mg/mL solution of *di-n-octyl phthalate R* in *tetrahydrofuran for chromatography R*.

Internal standard solution S4 5 µg/mL solution of *di-n-octyl phthalate R* in *anhydrous ethanol R*.

Test solution Cut 0.2 g of the material to be examined into pieces about 0.5 cm in length. Dissolve the pieces in 12.5 mL of internal standard solution S3 using a polytetrafluoroethylene magnetic stirring bar. Complete dissolution of the material to be examined is obtained after stirring for about 20-30 min. The poly(vinyl chloride) is precipitated as a white powder by adding dropwise 37.5 mL of *anhydrous ethanol R*. Centrifuge, then dilute 1.0 mL of the supernatant to 50.0 mL with *anhydrous ethanol R*. The final concentration of the internal standard in the test solution is 5 µg/mL.

The stock solution may be stored at 4 °C for up to 2 weeks.

Stock solution Dissolve 20.0 mg of *plastic additive 01 CRS* in internal standard solution S4 and dilute to 20.0 mL with the internal standard solution S4.

Reference solutions (a1)-(a5) Dilute the stock solution with internal standard solution S4 to obtain 5 reference solutions containing 10-40 µg/mL of *plastic additive 01 CRS*.

Column:
— *material*: fused silica;
— *size*: *l* = 30 m, Ø = 0.25 mm;
— *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

Carrier gas *helium for chromatography R*.

Flow rate 1 mL/min.

Split ratio 1:20.

Temperature:

	Time (min)	Temperature (°C)
Column	0	100
	0 - 3.3	100 → 200
	3.3 - 20	200 → 250
	20 - 22.5	250
	22.5 - 23	250 → 270
	23 - 25	270
	25 - 25.6	270 → 320
	25.6 - 30.6	320
Injection port		300

Detection Mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:
— quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
— *ion source temperature*: 230 °C;
— *acquisition system*: performed on full-scan (*m/z* = 40-350) and on single-ion monitoring (SIM) modes;
— *solvent delay*: 2.5 min;
— mass spectrometer parameters for the fragmentometric mode (SIM) set as follows:

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]
Plastic additive 01	149	167	279
DnOP (internal standard)	149	279	167

Injection 1 µL.

Relative retention With reference to di-*n*-octyl phthalate (retention time = about 22 min): plastic additive 01 = about 0.80.

The specificity of the detection is checked by monitoring 3 different ions for each substance using a mass spectrometer in SIM mode. Ion ratios are determined from the peak areas after the injection of a standard solution. The ratios in the table below are given for information.

Substance	Ion 1 [*m/z*]	Ion 2 [*m/z*]	Ion 3 [*m/z*]	Ion ratio 2/1 (%)	Ion ratio 3/1 (%)
Plastic additive 01	149	167	279	50	30
DnOP (internal standard)	149	279	167	/	/

System suitability:
— *repeatability*: maximum relative standard deviation of 1.0 per cent for the retention time of the peak due to plastic additive 01, determined on 6 injections of a reference solution situated in the middle of the calibration range (e.g. 20 µg/mL); maximum relative standard deviation of 3.0 per cent for the ratio of the area of the peak due to plastic additive 01 to that due to the internal standard, determined on 6 injections of a reference solution situated in the middle of the calibration range (e.g. 20 µg/mL).

From the calibration curve obtained with the reference solutions, calculate the percentage content of plastic additive 01 in the material to be examined.

Limit:
— *plastic additive 01*: maximum 40 per cent.

Plastic additive 03

Wash precipitate B2 obtained during the identification and contained in the tared sintered-glass filter (40) (*2.1.2*) with *anhydrous ethanol R*. Dry to constant mass over *diphosphorus pentoxide R* and weigh the filter. The residue weighs not more than 20 mg.

Infrared absorption spectrophotometry (*2.2.24*).

Preparation The residue obtained above. When the amount of residue is insufficient to prepare a disc, record the spectrum of the residue placed between 2 plates transparent to infrared radiation or examine by attenuated total reflectance (ATR).

Comparison *plastic additive 03 CRS.*

Plastic additives 04 and 05

Thin-layer chromatography (*2.2.27*).

Reference solutions Prepare 10 mg/mL solutions of *plastic additive 04 CRS* and *plastic additive 05 CRS*, respectively, in *toluene R*.

Plate *TLC silica gel F_{254} plate R.*

Mobile phase *toluene R.*

Application 0.5 mL of solution A1 obtained during the identification, as a band 30 mm by 3 mm, and 5 µL of each reference solution.

Development Over 2/3 of the plate.

Drying In air.

Detection Expose the plate to iodine vapour for 5 min.

Examine the chromatogram and locate the zone corresponding to plastic additives 04 and 05 ($R_F = 0$). Remove the area of silica gel corresponding to this zone. Similarly remove a corresponding area of silica gel as a blank reference. Separately shake both samples for 15 min with 40 mL of *methanol R*. Filter, rinse with 2 quantities, each of 10 mL, of *methanol R*, add the rinsings to the filtrate and evaporate to dryness. The difference between the masses of both residues is not more than 10 mg.

Barium

Maximum 5 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Ignite 1.0 g of the material to be examined in a silica crucible. Take up the residue with 10 mL of *hydrochloric acid R* and evaporate to dryness on a water-bath. Take up the residue with 20 mL of *0.1 M hydrochloric acid.*

Reference solution A solution containing 0.25 ppm of barium prepared by dilution of *barium standard solution (50 ppm Ba) R* with *0.1 M hydrochloric acid.*

Wavelength Use the emission of barium at 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the hydrochloric acid used.

Cadmium

Maximum 0.6 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Evaporate 10 mL of solution S1 to dryness. Take up the residue using 5 mL of a 1 per cent *V/V* solution of *hydrochloric acid R*, filter and dilute the filtrate to 10.0 mL with the same acid solution.

Reference solutions Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluting with a 1 per cent *V/V* solution of *hydrochloric acid R*.

Source Cadmium hollow-cathode lamp.

Wavelength 228.8 nm.

Atomisation device Air-acetylene flame.

Verify the absence of cadmium in the hydrochloric acid used.

Calcium

Maximum 0.07 per cent.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use the test solution prepared for the determination of barium.

Reference solution A solution containing 50.0 ppm of calcium prepared by dilution of *calcium standard solution (400 ppm Ca) R* with *0.1 M hydrochloric acid.*

Wavelength Use the emission of calcium at 315.89 nm, the spectral background being taken at 315.60 nm.

Verify the absence of calcium in the hydrochloric acid used.

Tin

Maximum 20 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Dilute solution S1 10-fold with *water R* immediately before use.

Reference solution Introduce 2 mL of *tin standard solution (5 ppm Sn) R* into a 50 mL flask containing 5 mL of a 20 per cent *V/V* solution of *sulfuric acid R* and dilute to 50 mL with *water R* immediately before use.

Wavelength Use the emission of tin at 189.99 nm, the spectral background being taken at 190.10 nm.

Verify the absence of tin in the hydrochloric acid used.

Zinc

Maximum 0.2 per cent.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Dilute solution S1 100-fold with *0.1 M hydrochloric acid.*

Reference solutions Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluting with *0.1 M hydrochloric acid.*

Source Zinc hollow-cathode lamp.

Wavelength 213.9 nm.

Atomisation device Air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Heavy metals (*2.4.8*)

Maximum 50 ppm.

To 10 mL of solution S1 add 0.5 mL of *phenolphthalein solution R* and then *strong sodium hydroxide solution R* until a pale pink colour is obtained. Dilute to 25 mL with *water R*. 12 mL of the solution complies with test A. Prepare the reference solution using *lead standard solution (2 ppm Pb) R.*

Water extractable substances

Maximum 0.3 per cent.

Evaporate 50.0 mL of solution S2 to dryness on a water-bath and dry in an oven at 100-105 °C to constant mass. Carry out a blank test with 50.0 mL of *water R*. The residue weighs not more than 7.5 mg taking into account the blank test.

ASSAY

Carry out the oxygen-flask method (*2.5.10*) using 50.0 mg of the material to be examined. Absorb the combustion products in 20 mL of *1 M sodium hydroxide*. To the solution obtained add 2.5 mL of *nitric acid R*. Titrate with *0.1 M silver nitrate*, determining the end-point potentiometrically (*2.2.20*). Carry out a blank titration.

1 mL of *0.1 M silver nitrate* is equivalent to 6.25 mg of poly(vinyl chloride).

B. Polyolefins

(Ph. Eur. method 3.1.3)

DEFINITION

Polyolefins are obtained by polymerisation of ethylene or propylene or by copolymerisation of these substances with not more than 25 per cent of higher homologues (C_4 to C_{10}) or of carboxylic acids or of esters. Certain materials may be mixtures of polyolefins.

PRODUCTION

Depending on the intended use of the polymers, they may contain additives to optimise their processing or their chemical, physical and mechanical properties. Unless otherwise justified and authorised, these additives are chosen from the following list, which specifies for each substance the maximum permitted content.

Polyolefins may contain at most 3 antioxidants, 1 or several lubricants or antiblocking agents as well as titanium dioxide as an opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07): maximum 0.125 per cent;
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09): maximum 0.3 per cent;
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-*S*-triazine-2,4,6(1*H*,3*H*,5*H*)-trione (plastic additive 13): maximum 0.3 per cent;
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate (plastic additive 11): maximum 0.3 per cent;
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08): maximum 0.3 per cent;
- dioctadecyl disulfide (plastic additive 15): maximum 0.3 per cent;
- 4,4′,4″-(2,4,6-trimethylbenzene-1,3,5-triyltrismethylene) tris[2,6-bis(1,1-dimethylethyl)phenol] (plastic additive 10): maximum 0.3 per cent;
- 2,2′-bis(octadecyloxy)-5,5′-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14): maximum 0.3 per cent;
- didodecyl 3,3′-thiodipropionate (plastic additive 16): maximum 0.3 per cent;
- dioctadecyl 3,3′-thiodipropionate (plastic additive 17): maximum 0.3 per cent;
- tris[2,4-bis(1,1-dimethylethyl)phenyl] phosphite (plastic additive 12): maximum 0.3 per cent;
- plastic additive 18: maximum 0.1 per cent;
- copolymer of dimethyl succinate and (4-hydroxy-2,2,6,6-tetramethylpiperidin-1-yl)ethanol (plastic additive 22): maximum 0.3 per cent.

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite: maximum 0.5 per cent;
- alkanamides: maximum 0.5 per cent;
- alkenamides: maximum 0.5 per cent;
- sodium silico-aluminate: maximum 0.5 per cent;
- silica (natural or synthetic, coated or uncoated): maximum 0.5 per cent;
- sodium benzoate: maximum 0.5 per cent;
- fatty acid esters or salts: maximum 0.5 per cent;
- trisodium phosphate: maximum 0.5 per cent;
- liquid paraffin: maximum 0.5 per cent;
- zinc oxide: maximum 0.5 per cent;
- talc: maximum 0.5 per cent;
- magnesium oxide: maximum 0.2 per cent;
- calcium stearate or zinc stearate or a mixture of both: maximum 0.5 per cent;
- titanium dioxide: maximum 4 per cent.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample (see chapter *3.2.2. Plastic containers and closures for pharmaceutical use* for the definition of 'type sample') is satisfactory for each production batch.

CHARACTERS

Appearance

Powder, beads, granules or, after transformation, sheets of varying thickness or containers.

Solubility

Practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in anhydrous ethanol, in hexane and in methanol.

They soften at temperatures between 65 °C and 165 °C. They burn with a blue flame.

IDENTIFICATION

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. Infrared absorption spectrophotometry (*2.2.24*).

Preparation To 0.25 g add 10 mL of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride slide or on a disc of *potassium bromide R* and evaporate the solvent in an oven at 80 °C.

Alternatively, the spectrum may be recorded directly on a cut piece of suitable size (sheets), granules or hot pressed films by attenuated total reflection (ATR).

The spectrum obtained is identical to that obtained with the material selected for the type sample.

B. It complies with the supplementary tests corresponding to the additives present (see Tests).

C. *(To be performed only on opacified material.)* In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulfate R* and heat until completely melted. Allow to cool and add 20 mL of *dilute sulfuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 mL of *phosphoric acid R* and 1 mL of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1

Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 mL of *water R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16) (*2.1.2*). Use within 4 h of preparation.

Solution S2

Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 mL of *toluene R* and boil under a reflux condenser, for 90 min with constant stirring. Allow to cool to 60 °C and add, with constant stirring, 120 mL of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 mL of a mixture of 40 mL of *toluene R* and 60 mL of *methanol R*, add the rinsings to the filtrate and dilute to 250 mL with the same mixture of solvents. Prepare a blank solution.

Solution S3
Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 mL of *0.1 M hydrochloric acid* and boil under a reflux condenser for 1 h with constant stirring. Allow to cool and decant the solution.

Appearance of solution
Solution S1 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity
To 100 mL of solution S1 add 0.15 mL of *BRP indicator solution R*. Not more than 1.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue.
To 100 mL of solution S1 add 0.2 mL of *methyl orange solution R*. Not more than 1.0 mL of *0.01 M hydrochloric acid* is required to initiate the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*)
Maximum 0.2, determined between wavelengths of 220 nm and 340 nm on solution S1.

Reducing substances
To 20 mL of solution S1 add 1 mL of *dilute sulfuric acid R* and 20 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 3.0 mL.

Extractable aluminium
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength Use the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable titanium *(not for materials opacified with titanium dioxide)*
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength Use the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable zinc
Maximum 1 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluting with *0.1 M hydrochloric acid*.

Source Zinc hollow-cathode lamp.

Wavelength 213.9 nm.

Atomisation device Air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Extractable heavy metals (*2.4.8*)
Maximum 2.5 ppm.

Evaporate 50 mL of solution S3 to about 5 mL on a water-bath and dilute to 20.0 mL with *water R*. 12 mL of the solution complies with test A. Prepare the reference solution using 2.5 mL of *lead standard solution (10 ppm Pb) R*.

Sulfated ash (*2.4.14*)
Maximum 1.0 per cent, determined on 5.0 g. This limit does not apply to material that has been opacified with titanium dioxide.

SUPPLEMENTARY TESTS
These tests are to be carried out, in whole or in part, only if required by the stated composition or the use of the material.

Phenolic antioxidants
Liquid chromatography (*2.2.29*).

Solvent mixture *acetonitrile R, tetrahydrofuran R* (50:50 *V/V*).

Test solution S21 Evaporate 50 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 mL of the solvent mixture. Prepare a blank solution from the blank solution corresponding to solution S2.

Test solution S22 Evaporate 50 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 mL of a mixture of equal volumes of *acetonitrile R* and a 10 g/L solution of *tert-butylhydroperoxide R* in *tetrahydrofuran R*. Close the flask and allow to stand for 1 h. Prepare a blank solution using the blank of solution S2.

Of the following reference solutions, prepare only those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a) Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (b) Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (c) *Prepare immediately before use.* Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (d) Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (e) Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (f) Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (g) Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (h) Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (i) Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (j) *Prepare immediately before use.* Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (k) Dissolve 20.0 mg of *plastic additive 18 CRS* in 10.0 mL of a mixture of equal volumes of *acetonitrile R* and a 10 g/L solution of *tert-butylhydroperoxide R* in *tetrahydrofuran R*. Allow to stand in a closed container for 1 h. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

A. If the substance to be examined contains plastic additive 07 and/or plastic additive 08, proceed as follows.

Column:
- *size*: *l* = 0.25 m, Ø = 4.6 mm;
- *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase *water for chromatography R, acetonitrile R* (30:70 *V/V*).

Flow rate 2 mL/min.

Detection Spectrophotometer at 280 nm.

Injection 20 µL of test solution S21, the corresponding blank solution, reference solution (a), and either the reference solution (d) or (e) or reference solutions (d) and (e).

Run time 30 min.

System suitability:
- *resolution*: minimum 5.0 between the peaks due to plastic additive 07 and plastic additive 08 in the chromatogram obtained with reference solution (a).

The chromatogram obtained with test solution S21 only shows peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatogram obtained with the blank solution.

Calculation of percentage contents:

For plastic additive 07 and/or 08, use the concentration of the corresponding reference substance in reference solutions (d) and/or (e).

Limits:
- *plastic additive 07*: maximum 0.125 per cent;
- *plastic additive 08*: maximum 0.3 per cent.

B. If the substance to be examined contains one or more of the following antioxidants:
- plastic additive 09;
- plastic additive 10;
- plastic additive 11;
- plastic additive 12;
- plastic additive 13;

proceed as described above with the following modifications.

Mobile phase *water for chromatography R, tetrahydrofuran R, acetonitrile R* (10:30:60 *V/V/V*).

Flow rate 1.5 mL/min.

Injection 20 µL of test solution S21, the corresponding blank solution, reference solution (b), reference solution (c) and the reference solutions of the antioxidants in the list above that are stated in the composition.

System suitability:
- *resolution*: minimum 2.0 between the peaks due to plastic additive 09 and plastic additive 10 in the chromatogram obtained with reference solution (b); minimum 2.0 between the peaks due to plastic additive 11 and plastic additive 12 in the chromatogram obtained with reference solution (c).

The chromatogram obtained with test solution S21 only shows peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatogram obtained with the blank solution.

Calculation of percentage contents:

For plastic additive 09, 10, 11, 12 and/or 13, use the concentration of the corresponding reference substance in reference solutions (g), (h), (i), (j) and/or (f).

Limits:
- *plastic additive 09*: maximum 0.3 per cent;
- *plastic additive 10*: maximum 0.3 per cent;
- *plastic additive 11*: maximum 0.3 per cent;
- *plastic additive 12*: maximum 0.3 per cent;
- *plastic additive 13*: maximum 0.3 per cent.

C. If the substance to be examined contains plastic additive 18, proceed as described for plastic additive 07 and/or plastic additive 08 with the following modifications.

Mobile phase *tetrahydrofuran R, acetonitrile R* (20:80 *V/V*).

Flow rate 1.5 mL/min.

Detection Spectrophotometer at 270 nm.

Injection 20 µL of test solution S22, the corresponding blank solution and reference solution (k).

Identification of peaks Use the chromatogram supplied with *plastic additive 18 CRS* and the chromatogram obtained with reference solution (k) to identify the peaks due to plastic additive 18.

Retention time Of the 2 principal peaks due to plastic additive 18: about 3.3 min and about 6.6 min.

The chromatogram obtained with test solution S22 shows 2 principal peaks due to plastic additive 18. The sum of the areas of these peaks is not less than 50 per cent of the sum of the areas of all the peaks due to plastic additive 18.

System suitability:
- *resolution*: minimum 6.0 between the 2 principal peaks in the chromatogram obtained with reference solution (k).

The chromatogram obtained with test solution S22 only shows peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatogram obtained with the blank solution.

Calculation of percentage content:
- sum up the areas of all the peaks due to plastic additive 18 eluting between 2.0 min and 9.5 min; use the concentration of *plastic additive 18 CRS* in reference solution (k).

Limit:
- *sum of the areas of the peaks due to plastic additive 18*: maximum 0.1 per cent; disregard any peak with an area less than 0.3 per cent of the total area.

Non-phenolic antioxidants

Thin-layer chromatography (*2.2.27*).

Test solution S23 Evaporate 100 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 mL of *acidified methylene chloride R*.

Reference solution (l) Dissolve 60 mg of *plastic additive 14 CRS* in 10 mL of *methylene chloride R*. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (m) Dissolve 60 mg of *plastic additive 15 CRS* in 10 mL of *methylene chloride R*. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (n) Dissolve 60 mg of *plastic additive 16 CRS* in 10 mL of *methylene chloride R*. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (o) Dissolve 60 mg of *plastic additive 17 CRS* in 10 mL of *methylene chloride R*. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (p) Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in 10 mL of *methylene chloride R*. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Plate *TLC silica gel F_{254} plate R*.

Mobile phase A *hexane R*.

Mobile phase B *methylene chloride R*.

Application 20 µL of test solution S23, reference solution (p) and the reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined.

Development A Over a path of 18 cm with mobile phase A.

Drying A In air.

Development B Over a path of 17 cm with mobile phase B.

Drying B In air.

Detection Examine in ultraviolet light at 254 nm; spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10-15 min.

System suitability Reference solution (p):
— the chromatogram shows 2 clearly separated spots.

Limit Any spots in the chromatogram obtained with test solution S23 are not more intense than the spots in the corresponding positions in the chromatograms obtained with the reference solutions.

Plastic additive 22

Liquid chromatography (*2.2.29*).

Test solution Evaporate 25 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 10 mL of *toluene R* and 10 mL of a 10 g/L solution of *tetrabutylammonium hydroxide R* in a mixture of 35 volumes of *toluene R* and 65 volumes of *anhydrous ethanol R*. Boil under a reflux condenser for 3 h. Allow to cool and filter if necessary.

Reference solution Dissolve 30 mg of *plastic additive 22 CRS* in 50 mL of *toluene R*. Add 1 mL of this solution to 25 mL of blank solution S2 and evaporate to dryness *in vacuo* at 45 °C. Dissolve the residue in 10 mL of *toluene R* and 10 mL of a 10 g/L solution of *tetrabutylammonium hydroxide R* in a mixture of 35 volumes of *toluene R* and 65 volumes of *anhydrous ethanol R*. Boil under a reflux condenser for 3 h. Allow to cool and filter if necessary.

Column:
— *size*: l = 0.25 m, Ø = 4.6 mm;
— *stationary phase*: *aminopropylsilyl silica gel for chromatography R* (5 µm).

Mobile phase *anhydrous ethanol R, hexane R* (11:89 *V/V*).

Flow rate 2 mL/min.

Detection Spectrophotometer at 227 nm.

Injection 20 µL.

Run time 10 min.

System suitability:
— *resolution*: minimum 7 between the peaks due to the 'diol' component and to the diluent of the reference solution.

Limit The area of the peak due to the 'diol' component from plastic additive 22 in the chromatogram obtained with the test solution is less than the corresponding peak in the chromatogram obtained with the reference solution.

Amides and stearates

Thin-layer chromatography (*2.2.27*).

Test solution Use test solution S23 described in the test for non-phenolic antioxidants.

Reference solution (q) Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in 10 mL of *methylene chloride R*.

Reference solution (r) Dissolve 40 mg of oleamide (*plastic additive 20 CRS*) in 20 mL of *methylene chloride R*.

Reference solution (s) Dissolve 40 mg of erucamide (*plastic additive 21 CRS*) in 20 mL of *methylene chloride R*.

Plate *TLC silica gel F_{254} plate R* (2 plates).

A. *Mobile phase*: *anhydrous ethanol R, trimethylpentane R* (25:75 *V/V*).

Application 10 µL of test solution S23 and reference solution (q).

Development Over a path of 10 cm.

Drying In air.

Detection Spray with a 2 g/L solution of *dichlorophenolindophenol, sodium salt R* in *anhydrous ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots.

Limit Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S23 is similar in position (R_F = about 0.5) but not more intense than the corresponding spot in the chromatogram obtained with reference solution (q).

B. *Mobile phase A*: *hexane R*.

Mobile phase B *methanol R, methylene chloride R* (5:95 *V/V*).

Application 10 µL of the test solution S23 and the reference solutions (r) and (s).

Development A Over a path of 13 cm with mobile phase A.

Drying A In air.

Development B Over a path of 10 cm with mobile phase B.

Drying B In air.

Detection Spray with a 40 g/L solution of *phosphomolybdic acid R* in *anhydrous ethanol R*. Heat in an oven at 120 °C until spots appear.

Limits Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S23 are similar in position (R_F = about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (r) and (s).

C. Polyethylene

1. Polyethylene Without Additives for Containers for Parenteral Preparations and for Ophthalmic Preparations

(Ph. Eur. method 3.1.4)

DEFINITION

Polyethylene without additives is obtained by polymerisation of ethylene under high pressure in the presence of oxygen or free-radical-forming initiators as catalyst.

CHARACTERS

Appearance

Beads, granules, powder or, after transformation, translucent sheets of varying thickness or containers.

Solubility

Practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in anhydrous ethanol, in hexane and in methanol.

It softens at temperatures beginning at 65 °C.

Relative density

0.910 to 0.937.

IDENTIFICATION

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. Infrared absorption spectrophotometry (*2.2.24*).

Preparation To 0.25 g add 10 mL of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride slide or on a disc of *potassium bromide R* and evaporate the solvent in an oven at 80 °C.

Alternatively, the spectrum may be recorded directly on a cut piece of suitable size (sheets), granules or hot pressed films by attenuated total reflection (ATR).

Absorption maxima *at some of the following wavenumbers (tolerance: ± 5 cm^{-1})*: at 2915 cm^{-1}, 2848 cm^{-1}, 1471 cm^{-1}, 1465 cm^{-1}, 729 cm^{-1} and 719 cm^{-1}.

The spectrum obtained is identical to that obtained with the material selected for the type sample (see chapter *3.2.2. Plastic containers and closures for pharmaceutical use* for the definition of 'type sample').

B. Additives (see Tests).

TESTS

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1

Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 mL of *water R* and heat under a reflux condenser for 5 h. Allow to cool and decant. Keep part of the solution for the test for appearance of solution. Filter the rest through a sintered glass filter (16) (*2.1.2*). Use within 4 h of preparation.

Solution S2

Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 mL of *toluene R* and boil under a reflux condenser with constant stirring for 90 min. Allow to cool to 60 °C and add, with contant stirring, 120 mL of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 mL of a mixture of 40 mL of *toluene R* and 60 mL of *methanol R*, add the rinsings to the filtrate and dilute to 250 mL with the same mixture of solvents. Prepare a blank solution.

Solution S3

Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 mL of *0.1 M hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution

Solution S1 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity

To 100 mL of solution S1 add 0.15 mL of *BRP indicator solution R*. Not more than 1.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue.

To 100 mL of solution S1 add 0.2 mL of *methyl orange solution R*. Not more than 1.0 mL of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*)

Maximum 0.2, determined between wavelengths of 220 nm and 340 nm on solution S1.

Reducing substances

To 20 mL of solution S1 add 1 mL of *dilute sulfuric acid R* and 20 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 mL.

Additives

Thin-layer chromatography (*2.2.27*).

Test solution Evaporate 50 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5 mL of *methylene chloride R*. Prepare a blank solution from the blank solution corresponding to solution S2.

Reference solution Dissolve 20 mg of *plastic additive 15 CRS* and 20 mg of *plastic additive 08 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent.

Plate *TLC silica gel G plate R.*

Mobile phase A *hexane R.*

Mobile phase B *methanol R, methylene chloride R* (5:95 *V/V*).

Application 10 µL.

Development A Over a path of 13 cm with mobile phase A.

Drying A In air.

Development B Over a path of 10 cm with mobile phase B.

Drying B In air.

Detection Spray with a 40 g/L solution of *phosphomolybdic acid R* in *ethanol (96 per cent) R* and heat at 120 °C until the spots appear in the chromatogram obtained with the reference solution.

System suitability Reference solution:

— the chromatogram shows 2 separated spots.

Limit No spot appears in the chromatogram obtained with the test solution, except for a spot which may be at the solvent front from the first development and which corresponds to oligomers. Disregard any spots corresponding to those obtained in the chromatogram with the blank solution.

Extractable heavy metals (*2.4.8*)

Maximum 2.5 ppm.

Evaporate 50 mL of solution S3 to about 5 mL on a water-bath and dilute to 20 mL with *water R*. 12 mL of solution complies with test A. Prepare the reference solution using 2.5 mL of *lead standard solution (10 ppm Pb) R*.

Sulfated ash (*2.4.14*)
Maximum 0.02 per cent, determined on 5.0 g.

2. Polyethylene With Additives for Containers for Parenteral Preparations and for Opthalmic Preparations

(Ph. Eur. method 3.1.5)

DEFINITION

Polyethylene with additives is obtained by polymerisation of ethylene under pressure in the presence of a catalyst or by copolymerisation of ethylene with not more than 25 per cent of higher alkene homologues (C_3 to C_{10}).

PRODUCTION

Depending on the intended use of the polymers, they may contain additives to optimise their processing or their chemical, physical and mechanical properties. Unless otherwise justified and authorised, these additives are chosen from the following list, which specifies for each substance the maximum permitted content.

Polyethylene may contain at most 3 antioxidants, 1 or several lubricants or antiblocking agents as well as titanium dioxide as an opacifying agent when the material must provide protection from light.

- butylhydroxytoluene (plastic additive 07): maximum 0.125 per cent;
- pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09): maximum 0.3 per cent;
- 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-*S*-triazine2,4,6(1*H*,3*H*,5*H*)-trione (plastic additive 13): maximum 0.3 per cent;
- octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate (plastic additive 11): maximum 0.3 per cent;
- ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08): maximum 0.3 per cent;
- dioctadecyl disulfide (plastic additive 15): maximum 0.3 per cent;
- 4,4′,4″-(2,4,6-trimethylbenzene-1,3,5-triyltrismethylene) tris[2,6-bis(1,1-dimethylethyl)phenol] (plastic additive 10): maximum 0.3 per cent;
- 2,2′-bis(octadecyloxy)-5,5′-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14): maximum 0.3 per cent;
- didodecyl 3,3′-thiodipropionate (plastic additive 16): maximum 0.3 per cent;
- dioctadecyl 3,3′-thiodipropionate (plastic additive 17): maximum 0.3 per cent;
- tris [2,4-bis(1,1-dimethylethyl)phenyl] phosphite (plastic additive 12): maximum 0.3 per cent.

The total of antioxidant additives listed above does not exceed 0.3 per cent.

- hydrotalcite: maximum 0.5 per cent;
- alkanamides: maximum 0.5 per cent;
- alkenamides: maximum 0.5 per cent;
- sodium silico-aluminate: maximum 0.5 per cent;
- silica (natural or synthetic, coated or uncoated): maximum 0.5 per cent;
- sodium benzoate: maximum 0.5 per cent;
- fatty acid esters or salts: maximum 0.5 per cent;
- trisodium phosphate: maximum 0.5 per cent;
- liquid paraffin: maximum 0.5 per cent;
- zinc oxide: maximum 0.5 per cent;
- magnesium oxide: maximum 0.2 per cent;
- calcium stearate or zinc stearate or a mixture of both: maximum 0.5 per cent;
- titanium dioxide only for materials for containers for ophthalmic use: maximum 4 per cent.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample (see chapter *3.2.2. Plastic containers and closures for pharmaceutical use* for the definition of 'type sample') is satisfactory for each production batch.

CHARACTERS

Appearance
Powder, beads, granules or, after transformation, translucent sheets of varying thicknesses or containers.

Solubility
Practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in anhydrous ethanol, in hexane and in methanol.

It softens at temperatures between 70 °C and 140 °C.

Relative density: 0.890 to 0.965.

IDENTIFICATION

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. Infrared absorption spectrophotometry (*2.2.24*).

Preparation To 0.25 g add 10 mL of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride slide or on a disc of *potassium bromide R* and evaporate the solvent in an oven at 80 °C.

Alternatively, the spectrum may be recorded directly on a cut piece of suitable size (sheets), granules or hot pressed films by attenuated total reflection (ATR).

Absorption maxima at some of the following wavenumbers (*tolerance:* ± *5 cm^{-1}*): at 2915 cm^{-1}, 2848 cm^{-1}, 1471 cm^{-1}, 1465 cm^{-1}, 729 cm^{-1} and 719 cm^{-1}.

The spectrum obtained is identical to that obtained with the material selected for the type sample.

B. It complies with the supplementary tests corresponding to the additives present (see Tests).

C. *(To be performed only on opacified material.)* In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulfate R* and heat until completely melted. Allow to cool and add 20 mL of *dilute sulfuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 mL of *phosphoric acid R* and 1 mL of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1
Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 mL of *water R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16) (*2.1.2*). Use within 4 h of preparation.

Solution S2
Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 mL of *toluene R* and boil under a reflux

condenser for 90 min with constant stirring. Allow to cool to 60 °C and add with continued stirring 120 mL of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 mL of a mixture of 40 mL of *toluene R* and 60 mL of *methanol R*, add the rinsings to the filtrate and dilute to 250 mL with the same mixture of solvents. Prepare a blank solution.

Solution S3

Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 mL of *0.1 M hydrochloric acid* and boil under a reflux condenser for 1 h with constant stirring. Allow to cool and decant the solution.

Appearance of solution

Solution S1 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity

To 100 mL of solution S1 add 0.15 mL of *BRP indicator solution R*. Not more than 1.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue.
To 100 mL of solution S1 add 0.2 mL of *methyl orange solution R*. Not more than 1.0 mL of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*)

Maximum 0.2, determined between wavelengths of 220 nm and 340 nm on solution S1.

Reducing substances

To 20 mL of solution S1 add 1 mL of *dilute sulfuric acid R* and 20 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 mL.

Extractable aluminium

Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength Use the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable chromium

Maximum 0.05 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *chromium standard solution (100 ppm Cr) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Wavelength Use the emission of chromium at 205.55 nm, the spectral background being taken as 205.50 nm.

Verify the absence of chromium in the hydrochloric acid used.

Extractable titanium

(not for materials opacified with titanium dioxide)

Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength Use the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable vanadium

Maximum 0.1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *vanadium standard solution (1 g/L V) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Wavelength Use the emission of vanadium at 292.40 nm, the spectral background being taken as 292.35 nm.

Verify the absence of vanadium in the hydrochloric acid used.

Extractable zinc

Maximum 1 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluting with *0.1 M hydrochloric acid*.

Source Zinc hollow-cathode lamp.

Wavelength 213.9 nm.

Atomisation device Air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Extractable zirconium

Maximum 0.1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *zirconium standard solution (1 g/L Zr) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Wavelength Use the emission of zirconium at 343.82 nm, the spectral background being taken as 343.92 nm.

Verify the absence of zirconium in the hydrochloric acid used.

Extractable heavy metals (*2.4.8*)

Maximum 2.5 ppm.

Evaporate 50 mL of solution S3 to about 5 mL on a water-bath and dilute to 20.0 mL with *water R*. 12 mL of the solution complies with test A. Prepare the reference solution using 2.5 mL of *lead standard solution (10 ppm Pb) R*.

Sulfated ash (*2.4.14*)

Maximum 1.0 per cent, determined on 5.0 g. This limit does not apply to material opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition of the material.

Phenolic antioxidants

Liquid chromatography (*2.2.29*).

Solvent mixture *acetonitrile R, tetrahydrofuran R* (50:50 *V/V*).

Test solution S21 Evaporate 50 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 mL of the solvent mixture. Prepare a blank solution from the blank solution corresponding to solution S2.

Of the following reference solutions, only prepare those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a) Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (b) Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (c) *Prepare immediately before use.* Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (d) Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (e) Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (f) Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (g) Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (h) Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (i) Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (j) *Prepare immediately before use.* Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

A. If the substance to be examined contains plastic additive 07 and/or plastic additive 08, proceed as follows.

Column:
- *size*: *l* = 0.25 m, Ø = 4.6 mm;
- *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase *water for chromatography R, acetonitrile R* (30:70 *V/V*).

Flow rate 2 mL/min.

Detection Spectrophotometer at 280 nm.

Injection 20 µL of test solution S21, the corresponding blank solution, reference solution (a), and either reference solution (d) or (e), or reference solutions (d) and (e).

Run time 30 min.

System suitability:
- *resolution*: minimum 5.0 between the peaks due to plastic additive 07 and plastic additive 08 in the chromatogram obtained with reference solution (a).

The chromatogram obtained with test solution S21 only shows peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatogram obtained with the blank solution.

Calculation of percentage contents:

For plastic additive 07 and/or 08, use the concentration of the corresponding reference substance in reference solutions (d) and/or (e).

Limits:
- *plastic additive 07*: maximum 0.125 per cent;
- *plastic additive 08*: maximum 0.3 per cent.

B. If the substance to be examined contains one or more of the following antioxidants:
- plastic additive 09;
- plastic additive 10;
- plastic additive 11;
- plastic additive 12;
- plastic additive 13;

proceed as described above with the following modifications.

Mobile phase *water for chromatography R, tetrahydrofuran R, acetonitrile R* (10:30:60 *V/V/V*).

Flow rate 1.5 mL/min.

Injection 20 µL of test solution S21, the corresponding blank solution, reference solution (b), reference solution (c) and the reference solutions of the antioxidants in the list above that are stated in the composition.

System suitability:
- *resolution*: minimum 2.0 between the peaks due to plastic additive 09 and plastic additive 10 in the chromatogram obtained with reference solution (b); minimum 2.0 between the peaks due to plastic additive 11 and plastic additive 12 in the chromatogram obtained with reference solution (c).

The chromatogram obtained with test solution S21 only shows peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatogram obtained with the blank solution.

Calculation of percentage contents:

For plastic additive 09, 10, 11, 12 and/or 13, use the concentration of the corresponding reference substance in reference solutions (g), (h), (i), (j) and/or (f).

Limits:
- *plastic additive 09*: maximum 0.3 per cent;
- *plastic additive 10*: maximum 0.3 per cent;
- *plastic additive 11*: maximum 0.3 per cent;
- *plastic additive 12*: maximum 0.3 per cent;
- *plastic additive 13*: maximum 0.3 per cent.

Non-phenolic antioxidants

Thin-layer chromatography (*2.2.27*).

Test solution S22 Evaporate 100 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 mL of *acidified methylene chloride R*.

Reference solution (k) Dissolve 60 mg of *plastic additive 14 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (l) Dissolve 60 mg of *plastic additive 15 CRS* in *methylene chloride R* and dilute to 10 mL

with the same solvent. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (m) Dissolve 60 mg of *plastic additive 16 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (n) Dissolve 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Reference solution (o) Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of this solution to 10 mL with *acidified methylene chloride R*.

Plate *TLC silica gel F_{254} plate R*.

Mobile phase A *hexane R*.

Mobile phase B *methylene chloride R*.

Application 20 µL of test solution S22, reference solution (o) and reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined.

Development A Over a path of 18 cm with mobile phase A.

Drying A In air.

Development B Over a path of 17 cm with mobile phase B.

Drying B In air.

Detection Examine in ultraviolet light at 254 nm, spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10-15 min.

System suitability Reference solution (o):
— the chromatogram shows 2 clearly separated spots.

Limits Any spots in the chromatogram obtained with test solution S22 are not more intense than the spots in the same positions in the chromatograms obtained with the reference solutions.

Amides and stearates

Thin-layer chromatography (*2.2.27*).

Test solution Use test solution S22 described in the test for non-phenolic antioxidants.

Reference solution (p) Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in *methylene chloride R* and dilute to 10 mL with the same solvent.

Reference solution (q) Dissolve 40 mg of *plastic additive 20 CRS* in *methylene chloride R* and dilute to 20 mL with the same solvent.

Reference solution (r) Dissolve 40 mg of *plastic additive 21 CRS* in *methylene chloride R* and dilute to 20 mL with the same solvent.

Plates *TLC silica gel F_{254} plate R* (2 plates).

A. *Mobile phase: anhydrous ethanol R, trimethylpentane R* (25:75 *V/V*).

Application 10 µL of test solution S22 and reference solution (p).

Development Over a path of 10 cm.

Drying In air.

Detection Spray with a 2 g/L solution of *dichlorophenolindophenol, sodium salt R* in *anhydrous ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots.

Limit Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S22 is similar in position (R_F = about 0.5) but not more intense than the corresponding spot in the chromatogram obtained with reference solution (p).

B. *Mobile phase A: hexane R*.

Mobile phase B *methanol R, methylene chloride R* (5:95 *V/V*).

Application 10 µL of test solution S22 and reference solutions (q) and (r).

Development A Over a path of 13 cm with mobile phase A.

Drying A In air.

Development B Over a path of 10 cm with mobile phase B.

Drying B In air.

Detection Spray with a 40 g/L solution of *phosphomolybdic acid R* in *anhydrous ethanol R* and heat in an oven at 120 °C until spots appear.

Limits Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with the test solution S22 are similar in position (R_F = about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (q) and (r).

D. Polypropylene for Containers and Closures for Parenteral Preparations and Ophthalmic Preparations

(Ph. Eur. method 3.1.6)

DEFINITION

Polypropylene consists of the homopolymer of propylene or of a copolymer of propylene with not more than 25 per cent of ethylene or of a mixture (alloy) of polypropylene with not more than 25 per cent of polyethylene. It may contain additives.

PRODUCTION

Depending on the intended use of the polymers, they may contain additives to optimise their processing or their chemical, physical and mechanical properties. Unless otherwise justified and authorised, these additives are chosen from the following list, which specifies for each substance the maximum permitted content.

Polypropylene may contain at most 3 antioxidants, 1 or several lubricants or antiblocking agents as well as titanium dioxide as an opacifying agent when the material must provide protection from light.

— butylhydroxytoluene (plastic additive 07): maximum 0.125 per cent;
— pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09): maximum 0.3 per cent;
— 1,3,5-tris(3,5-di-*tert*-butyl-4-hydroxybenzyl)-*s*-triazine-2,4,6(1*H*,3*H*,5*H*)-trione (plastic additive 13): maximum 0.3 per cent;
— octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate, (plastic additive 11): maximum 0.3 per cent;
— ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl]butanoate] (plastic additive 08): maximum 0.3 per cent;

— dioctadecyl disulfide (plastic additive 15): maximum 0.3 per cent;
— 2,2′,2″,6,6′,6″-hexa-*tert*-butyl-4,4′,4″-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol (plastic additive 10): maximum 0.3 per cent;
— 2,2′-bis(octadecyloxy)-5,5′-spirobi[1,3,2-dioxaphosphinane] (plastic additive 14): maximum 0.3 per cent;
— didodecyl 3,3′-thiodipropionate (plastic additive 16): maximum 0.3 per cent;
— dioctadecyl 3,3′-thiodipropionate (plastic additive 17): maximum 0.3 per cent;
— tris(2,4-di-*tert*-butylphenyl) phosphite (plastic additive 12): maximum 0.3 per cent.

The total of antioxidant additives listed above does not exceed 0.3 per cent.
— hydrotalcite: maximum 0.5 per cent;
— alkanamides: maximum 0.5 per cent;
— alkenamides: maximum 0.5 per cent;
— sodium silico-aluminate: maximum 0.5 per cent;
— silica (natural or synthetic, coated or uncoated): maximum 0.5 per cent;
— sodium benzoate: maximum 0.5 per cent;
— fatty acid esters or salts: maximum 0.5 per cent;
— trisodium phosphate: maximum 0.5 per cent;
— liquid paraffin: maximum 0.5 per cent;
— zinc oxide: maximum 0.5 per cent;
— talc: maximum 0.5 per cent;
— magnesium oxide: maximum 0.2 per cent;
— calcium stearate or zinc stearate or a mixture of both: maximum 0.5 per cent;
— titanium dioxide, only for materials for containers for ophthalmic use: maximum 4 per cent.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample (see chapter *3.2.2. Plastic containers and closures for pharmaceutical use* for the definition of 'type sample') is satisfactory for each production batch.

CHARACTERS

Appearance
Powder, beads, granules or, after transformation, translucent sheets of varying thicknesses or containers.

Solubility
Practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in anhydrous ethanol, in hexane and in methanol.

It softens at temperatures beginning at about 120 °C.

IDENTIFICATION

If necessary, cut the samples of material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

A. Infrared absorption spectrophotometry (*2.2.24*).

Preparation To 0.25 g add 10 mL of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride slide or on a disc of *potassium bromide R* and evaporate the solvent in an oven at 80 °C.

Alternatively, the spectrum may be recorded directly on a cut piece of suitable size (sheets), granules or hot pressed films by attenuated total reflection (ATR).

Absorption maxima at some of the following wavenumbers (tolerance: ± 5 cm^{-1}) At 1375 cm^{-1}, 1170 cm^{-1}, 995 cm^{-1} and 973 cm^{-1}.

The spectrum obtained is identical to that obtained with the material selected for the type sample.

B. It complies with the supplementary tests corresponding to the additives present (see Tests).

C. *(To be performed only on opacified material.)* In a platinum crucible, mix about 20 mg with 1 g of *potassium hydrogen sulfate R* and heat until completely melted. Allow to cool and add 20 mL of *dilute sulfuric acid R*. Heat gently. Filter the resulting solution. To the filtrate add 1 mL of *phosphoric acid R* and 1 mL of *strong hydrogen peroxide solution R*. If the substance is opacified with titanium dioxide, an orange-yellow colour develops.

TESTS

If necessary, cut the samples of material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1
Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 mL of *water R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16) (*2.1.2*). Use within 4 h of preparation.

Solution S2
Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 mL of *toluene R* and boil under a reflux condenser for 90 min, with constant stirring. Allow to cool to 60 °C and add, with constant stirring, 120 mL of *methanol R*. Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 mL of a mixture of 40 mL of *toluene R* and 60 mL of *methanol R*, add the rinsings to the filtrate and dilute to 250 mL with the same mixture of solvents. Prepare a blank solution.

Solution S3
Place 100 g in a conical borosilicate-glass flask with a ground-glass neck. Add 250 mL of *0.1 M hydrochloric acid* and boil under a reflux condenser with constant stirring for 1 h. Allow to cool and decant the solution.

Appearance of solution
Solution S1 is not more opalescent than reference suspension II (*2.2.1*) and is colourless (*2.2.2, Method II*).

Acidity or alkalinity
To 100 mL of solution S1 add 0.15 mL of *BRP indicator solution R*. Not more than 1.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue.
To 100 mL of solution S1 add 0.2 mL of *methyl orange solution R*. Not more than 1.0 mL of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*)
Maximum 0.2, determined between wavelengths of 220 nm to 340 nm on solution S1.

Reducing substances
To 20 mL of solution S1 add 1 mL of *dilute sulfuric acid R* and 20 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 mL.

Extractable aluminium
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength Use the emission of aluminium at 396.15 nm, the spectral background being taken as 396.25 nm.

Verify the absence of aluminium in the hydrochloric acid used.

Extractable chromium
Maximum 0.05 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *chromium standard solution (100 ppm Cr) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Wavelength Use the emission of chromium at 205.55 nm, the spectral background being taken as 205.50 nm.

Verify the absence of chromium in the hydrochloric acid used.

Extractable titanium
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength Use the emission of titanium at 336.12 nm, the spectral background being taken as 336.16 nm.

Verify the absence of titanium in the hydrochloric acid used.

Extractable vanadium
Maximum 0.1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *vanadium standard solution (1 g/L V) R*, diluting with a mixture of 2 volumes of *hydrochloric acid R* and 8 volumes of *water R*.

Wavelength Use the emission of vanadium at 292.40 nm, the spectral background being taken as 292.35 nm.

Verify the absence of vanadium in the hydrochloric acid used.

Extractable zinc
Maximum 1 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution Use solution S3.

Reference solutions Prepare the reference solutions using *zinc standard solution (10 ppm Zn) R*, diluting with *0.1 M hydrochloric acid*.

Source Zinc hollow-cathode lamp.

Wavelength 213.9 nm.

Atomisation device Air-acetylene flame.

Verify the absence of zinc in the hydrochloric acid used.

Extractable heavy metals (*2.4.8*)
Maximum 2.5 ppm.

Evaporate 50 mL of solution S3 to about 5 mL on a water-bath and dilute to 20.0 mL with *water R*. 12 mL of the solution complies with test A. Prepare the reference solution using 2.5 mL of *lead standard solution (10 ppm Pb) R*.

Sulfated ash (*2.4.14*)
Maximum 1.0 per cent, determined on 5.0 g. This limit does not apply to material that has been opacified with titanium dioxide.

SUPPLEMENTARY TESTS

These tests are to be carried out, in whole or in part, only if required by the stated composition of the material.

Phenolic antioxidants
Liquid chromatography (*2.2.29*).

Solvent mixture *acetonitrile R, tetrahydrofuran R* (50:50 *V/V*).

Test solution S21 Evaporate 50 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 mL of the solvent mixture. Prepare a blank solution from the blank solution corresponding to solution S2.

Of the following reference solutions, only prepare those that are necessary for the analysis of the phenolic antioxidants stated in the composition of the substance to be examined.

Reference solution (a) Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) and 60.0 mg of *plastic additive 08 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (b) Dissolve 60.0 mg of *plastic additive 09 CRS* and 60.0 mg of *plastic additive 10 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (c) *Prepare immediately before use.* Dissolve 60.0 mg of *plastic additive 11 CRS* and 60.0 mg of *plastic additive 12 CRS* in 10 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (d) Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07) in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (e) Dissolve 60.0 mg of *plastic additive 08 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (f) Dissolve 60.0 mg of *plastic additive 13 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (g) Dissolve 60.0 mg of *plastic additive 09 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (h) Dissolve 60.0 mg of *plastic additive 10 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (i) Dissolve 60.0 mg of *plastic additive 11 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

Reference solution (j) *Prepare immediately before use.* Dissolve 60.0 mg of *plastic additive 12 CRS* in 10.0 mL of the solvent mixture. Dilute 2.0 mL of this solution to 50.0 mL with the solvent mixture.

A. If the substance to be examined contains plastic additive 07 and/or plastic additive 08, proceed as follows.

Column:
— *size*: *l* = 0.25 m, Ø = 4.6 mm;

— *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase *water for chromatography R, acetonitrile R* (30:70 *V/V*).

Flow rate 2 mL/min.

Detection Spectrophotometer at 280 nm.

Injection 20 µL of test solution S21, the corresponding blank solution, reference solution (a), and either reference solution (d) or (e), or reference solutions (d) and (e).

Run time 30 min.

System suitability:

— *resolution*: minimum 5.0 between the peaks due to plastic additive 07 and plastic additive 08 in the chromatogram obtained with reference solution (a).

The chromatogram obtained with test solution S21 only shows peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatogram obtained with the blank solution.

Calculation of percentage contents:

For plastic additive 07 and/or 08, use the concentration of the corresponding reference substance in reference solutions (d) and/or (e).

Limits:

— *plastic additive 07*: maximum 0.125 per cent;

— *plastic additive 08*: maximum 0.3 per cent.

B. If the substance to be examined contains one or more of the following antioxidants:

— plastic additive 09;

— plastic additive 10;

— plastic additive 11;

— plastic additive 12;

— plastic additive 13;

proceed as described above with the following modifications.

Mobile phase *water for chromatography R, tetrahydrofuran R, acetonitrile R* (10:30:60 *V/V/V*).

Flow rate 1.5 mL/min.

Injection 20 µL of test solution S21, the corresponding blank solution, reference solution (b), reference solution (c) and the reference solutions of the antioxidants in the list above that are stated in the composition.

System suitability:

— *resolution*: minimum 2.0 between the peaks due to plastic additive 09 and plastic additive 10 in the chromatogram obtained with reference solution (b); minimum 2.0 between the peaks due to plastic additive 11 and plastic additive 12 in the chromatogram obtained with reference solution (c).

The chromatogram obtained with test solution S21 only shows peaks due to antioxidants stated in the composition and minor peaks that also appear in the chromatogram obtained with the blank solution.

Calculation of percentage contents:

For plastic additive 09, 10, 11, 12 and/or 13, use the concentration of the corresponding reference substance in reference solutions (g), (h), (i), (j) and/or (f).

Limits:

— *plastic additive 09*: maximum 0.3 per cent;

— *plastic additive 10*: maximum 0.3 per cent;

— *plastic additive 11*: maximum 0.3 per cent;

— *plastic additive 12*: maximum 0.3 per cent;

— *plastic additive 13*: maximum 0.3 per cent.

Non-phenolic antioxidants

Thin-layer chromatography (*2.2.27*).

Test solution S22 Evaporate 100 mL of solution S2 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 mL of *acidified methylene chloride R*.

Reference solution (k) Dissolve 60 mg of *plastic additive 14 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of the solution to 10 mL with *acidified methylene chloride R*.

Reference solution (l) Dissolve 60 mg of *plastic additive 15 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of the solution to 10 mL with *acidified methylene chloride R*.

Reference solution (m) Dissolve 60 mg of *plastic additive 16 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of the solution to 10 mL with *acidified methylene chloride R*.

Reference solution (n) Dissolve 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of the solution to 10 mL with *acidified methylene chloride R*.

Reference solution (o) Dissolve 60 mg of *plastic additive 16 CRS* and 60 mg of *plastic additive 17 CRS* in *methylene chloride R* and dilute to 10 mL with the same solvent. Dilute 2 mL of the solution to 10 mL with *acidified methylene chloride R*.

Plate *TLC silica gel F_{254} plate R*.

Mobile phase A *hexane R*.

Mobile phase B *methylene chloride R*.

Application 20 µL of test solution S22, reference solution (o) and reference solutions corresponding to all the phenolic and non-phenolic antioxidants mentioned in the type composition of the material to be examined.

Development A Over a path of 18 cm with mobile phase A.

Drying A In air.

Development B Over a path of 17 cm with mobile phase B.

Drying B In air.

Detection Examine in ultraviolet light at 254 nm; spray with *alcoholic iodine solution R* and examine in ultraviolet light at 254 nm after 10-15 min.

System suitability Reference solution (o):

— the chromatogram shows 2 clearly separated spots.

Limits Any spots in the chromatogram obtained with test solution S22 are not more intense than the spots in the same positions in the chromatograms obtained with the reference solutions.

Amides and stearates

Thin-layer chromatography (*2.2.27*).

Test solution Use test solution S22 described in the test for non-phenolic antioxidants.

Reference solution (p) Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in *methylene chloride R* and dilute to 10 mL with the same solvent.

Reference solution (q) Dissolve 40 mg of *plastic additive 20 CRS* in *methylene chloride R* and dilute to 20 mL with the same solvent.

Reference solution (r) Dissolve 40 mg of *plastic additive 21 CRS* in *methylene chloride R* and dilute to 20 mL with the same solvent.

Plate *TLC silica gel F_{254} plate R* (2 plates).

A. *Mobile phase*: *anhydrous ethanol R, trimethylpentane R* (25:75 *V/V*).

Application 10 µL of solution S22 and reference solution (p).

Development Over a path of 10 cm.

Drying In air.

Detection Spray with a 2 g/L solution of *dichlorophenolindophenol, sodium salt R* in *anhydrous ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots.

Limit Any spot corresponding to plastic additive 19 in the chromatogram obtained with test solution S22 is similar in position (R_F = about 0.5) but not more intense than the corresponding spot in the chromatogram obtained with reference solution (p).

B. *Mobile phase A*: *hexane R.*

Mobile phase B *methanol R, methylene chloride R* (5:95 *V/V*).

Application 10 µL of solution S22 and reference solutions (q) and (r).

Development A Over a path of 13 cm with mobile phase A.

Drying A In air.

Development B Over a path of 10 cm with mobile phase B.

Drying B In air.

Detection Spray with a 40 g/L solution of *phosphomolybdic acid R* in *anhydrous ethanol R*; heat in an oven at 120 °C until spots appear.

Limits Any spots corresponding to plastic additive 20 or plastic additive 21 in the chromatogram obtained with test solution S22 are similar in position (R_F = about 0.2) but not more intense than the corresponding spots in the chromatograms obtained with reference solutions (q) and (r).

E. Poly(Ethylene - Vinyl Acetate) for Containers and Tubing for Total Parenteral Nutrition Preparations

(Ph. Eur. method 3.1.7)

DEFINITION

Poly(ethylene - vinyl acetate), complying with the following requirements, is suitable for the manufacture of containers and tubing for total parenteral nutrition preparations. It is obtained by copolymerisation of mixtures of ethylene and vinyl acetate.

Content of vinyl acetate:

— *material used for containers*: a defined quantity of not more than 25 per cent;

— *material used for tubing*: a defined quantity of not more than 30 per cent.

PRODUCTION

Depending on the intended use of the polymers, they may contain additives to optimise their processing or their chemical, physical and mechanical properties. Unless otherwise justified and authorised, these additives are chosen from the following list, which specifies for each substance the maximum permitted content.

Poly(ethylene - vinyl acetate) may contain not more than 3 of the following antioxidants:

— butylhydroxytoluene (plastic additive 07): maximum 0.125 per cent;

— pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate] (plastic additive 09): maximum 0.2 per cent;

— octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate (plastic additive 11): maximum 0.2 per cent;

— tris(2,4-di-*tert*-butylphenyl) phosphite (plastic additive 12): maximum 0.2 per cent;

— 2,2′,2″,6,6′,6″-hexa-*tert*-butyl-4,4′,4″-[(2,4,6-trimethyl-1,3,5-benzenetriyl)trismethylene]triphenol (plastic additive 10): maximum 0.2 per cent.

It may also contain:

— oleamide (plastic additive 20): maximum 0.5 per cent;

— erucamide (plastic additive 21): maximum 0.5 per cent;

— calcium stearate or zinc stearate or a mixture of both: maximum 0.5 per cent;

— calcium carbonate or potassium hydroxide: maximum 0.5 per cent;

— colloidal silica: maximum 0.2 per cent.

The supplier of the material must be able to demonstrate that the qualitative and quantitative composition of the type sample (see chapter *3.2.2. Plastic containers and closures for pharmaceutical use* for the definition of 'type sample') is satisfactory for each production batch.

CHARACTERS

Appearance

Beads, granules or, after transformation, translucent sheets or tubing of varying thickness or samples of finished objects.

Solubility

Practically insoluble in water, soluble in hot aromatic hydrocarbons, practically insoluble in anhydrous ethanol, in methanol and in hexane, which dissolves, however, low molecular mass polymers.

It burns with a blue flame.

The temperature at which the substance softens changes with the vinyl acetate content: from about 100 °C for contents of a few per cent to about 70 °C for contents of 30 per cent.

IDENTIFICATION

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Infrared absorption spectrophotometry (*2.2.24*).

Preparation To 0.25 g add 10 mL of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a sodium chloride slide or on a disc of *potassium bromide R* and evaporate the solvent in an oven at 80 °C.

Alternatively, the spectrum may be recorded directly on a cut piece of suitable size (sheets), granules or hot pressed films by attenuated total reflection (ATR).

Absorption maxima (tolerance: ± 5 cm^{-1}) At 2920 - 2850 cm^{-1}, 1740 cm^{-1}, 1240 cm^{-1}, 1020 cm^{-1}, 720 cm^{-1} and 610 cm^{-1}.

The spectrum obtained is identical to that obtained with the material selected for the type sample.

TESTS

If necessary, cut the samples of the material to be examined into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S1

Place 2.0 g in a conical borosilicate-glass flask with a ground-glass neck. Add 80 mL of *toluene R* and boil under a reflux condenser for 90 min, with constant stirring. Allow to cool to 60 °C and add, with constant stirring, 120 mL of *methanol R.*

Filter the solution through a sintered-glass filter (16) (*2.1.2*). Rinse the flask and the filter with 25 mL of a mixture of 40 mL of *toluene R* and 60 mL of *methanol R*, add the rinsings to the filtrate and dilute to 250 mL with the same mixture of solvents.

Solution S2

Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 mL of *water R* and boil under a reflux condenser for 5 h. Allow to cool and decant. Reserve a portion of the solution for the test for appearance of solution and filter the rest through a sintered-glass filter (16) (*2.1.2*). Use within 4 h of preparation.

Appearance of solution

Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity

To 100 mL of solution S2 add 0.15 mL of *BRP indicator solution R*. Not more than 1.0 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To 100 mL of solution S2 add 0.2 mL of *methyl orange solution R*. Not more than 1.5 mL of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Absorbance (*2.2.25*)

Maximum 0.2, determined between wavelengths of 220 nm and 340 nm on solution S2.

Reducing substances

To 20 mL of solution S2 add 1 mL of *dilute sulfuric acid R* and 20 mL of *0.002 M potassium permanganate*. Boil under a reflux condenser for 3 min and cool immediately. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not more than 0.5 mL.

Amides and stearates

Thin-layer chromatography (*2.2.27*).

Test solution Evaporate 100 mL of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 2 mL of *acidified methylene chloride R*.

Reference solution (a) Dissolve 20 mg of *stearic acid CRS* (plastic additive 19) in 10 mL of *methylene chloride R*.

Reference solution (b) Dissolve 40 mg of *plastic additive 20 CRS* in 20 mL of *methylene chloride R*.

Reference solution (c) Dissolve 40 mg of *plastic additive 21 CRS* in 20 mL of *methylene chloride R*.

Plates *TLC silica gel F_{254} plate R* (2 plates).

A. *Mobile phase: anhydrous ethanol R, trimethylpentane R* (25:75 *V/V*).

Application 10 µL.

Development Over a path of 10 cm.

Drying In air.

Detection Spray with a 2 g/L solution of *dichlorophenolindophenol, sodium salt R* in *anhydrous ethanol R* and heat in an oven at 120 °C for a few minutes to intensify the spots.

Limit Any spot corresponding to plastic additive 19 in the chromatogram obtained with the test solution is not more intense than the spot in the chromatogram obtained with reference solution (a).

B. *Mobile phase A: hexane R.*

Mobile phase B *methanol R, methylene chloride R* (5:95 *V/V*).

Application 10 µL.

Development A Over a path of 13 cm with mobile phase A.

Drying A In air.

Development B Over a path of 10 cm with mobile phase B.

Drying B In air.

Detection Spray with a 40 g/L solution of *phosphomolybdic acid R* in *anhydrous ethanol R* and heat at 120 °C until spots appear.

Limit Any spots corresponding to plastic additive 21 or plastic additive 20 in the chromatogram obtained with the test solution are not more intense than the spots in the chromatograms obtained with reference solutions (b) and (c) respectively.

Phenolic antioxidants

Liquid chromatography (*2.2.29*).

Solvent mixture *acetonitrile R, tetrahydrofuran R* (50:50 *V/V*).

Test solution (a) Evaporate 50 mL of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 mL of the solvent mixture.

Test solution (b) Evaporate 50 mL of solution S1 to dryness *in vacuo* at 45 °C. Dissolve the residue in 5.0 mL of *methylene chloride R*.

Reference solution (a) Dissolve 25.0 mg of *butylhydroxytoluene CRS* (plastic additive 07), 40.0 mg of *plastic additive 10 CRS*, 40.0 mg of *plastic additive 09 CRS* and 40.0 mg of *plastic additive 11 CRS* in 10 mL of the solvent mixture. Dilute 2 mL of the solution to 50.0 mL with the solvent mixture.

Reference solution (b) Dissolve 40.0 mg of *plastic additive 11 CRS* and 40.0 mg of *plastic additive 12 CRS* in 10 mL of *methylene chloride R*. Dilute 2 mL of the solution to 50.0 mL with *methylene chloride R*.

Column:

— *size: l* = 0.25 m; Ø = 4.6 mm;

— *stationary phase: octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase *water R, tetrahydrofuran R, acetonitrile R* (10:30:60 *V/V/V*).

Flow rate 1.5 mL/min.

Detection Spectrophotometer at 280 nm.

Injection 20 µL of test solution (a) and reference solution (a).

System suitability Reference solution (a):

— *resolution:* minimum 2.0 between the peaks due to plastic additive 09 and plastic additive 10;

— *number of theoretical plates:* minimum 2500, calculated for the peak due to plastic additive 07.

Limits:

— the chromatogram obtained with test solution (a) shows only principal peaks corresponding to the peaks in the chromatogram obtained with reference solution (a) with a retention time greater than 2 min;

— the areas of the peaks in the chromatogram obtained with test solution (a) are not greater than those of the corresponding peaks in the chromatogram obtained with reference solution (a), except for the last peak eluted in the chromatogram obtained with reference solution (a).

If the chromatogram obtained with test solution (a) shows a peak with the same retention time as the last antioxidant

eluted from reference solution (a), carry out the test as described with the following modifications.

Mobile phase *water R, 2-propanol R, methanol R* (5:45:50 *V/V/V*).

Injection 20 µL of test solution (b) and reference solution (b).

System suitability Reference solution (b):
— *resolution*: minimum 2.0 between the peaks due to plastic additive 11 and plastic additive 12.

Limits:
— the chromatogram obtained with test solution (b) shows only principal peaks corresponding to the peaks in the chromatogram obtained with reference solution (b) with a retention time greater than 3 min;
— the areas of the peaks in the chromatogram obtained with test solution (b) are not greater than those of the corresponding peaks in the chromatogram obtained with reference solution (b).

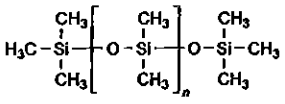
Sulfated ash (*2.4.14*)
Maximum 1.2 per cent, determined on 5.0 g.

ASSAY
Introduce 0.250 g to 1.000 g of the substance to be examined, according to the vinyl acetate content of the copolymer to be examined, into a 300 mL conical flask with a ground-glass neck containing a magnetic stirrer.
Add 40 mL of *xylene R*. Boil under a reflux condenser with stirring for 4 h. Stirring continuously, allow to cool until precipitation begins before slowly adding 25.0 mL of *alcoholic potassium hydroxide solution R1*. Boil again under a reflux condenser with stirring for 3 h. Allow to cool with continued stirring, rinse the condenser with 50 mL of *water R* and add 30.0 mL of *0.05 M sulfuric acid* to the flask. Transfer the contents of the flask into a 400 mL beaker; rinse the flask with 2 quantities, each of 50 mL, of a 200 g/L solution of *anhydrous sodium sulfate R* and 3 quantities, each of 20 mL, of *water R* and add all the rinsings to the beaker containing the initial solution. Titrate the excess sulfuric acid with *0.1 M sodium hydroxide*, determining the end-point potentiometrically (*2.2.20*). Carry out a blank titration.
1 mL of *0.05 M sulfuric acid* is equivalent to 8.609 mg of vinyl acetate.

F. Silicone

1. Silicone Oil Used as a Lubricant

(Ph. Eur. method 3.1.8)



DEFINITION
Silicone oil used as a lubricant is a poly(dimethylsiloxane) obtained by hydrolysis and polycondensation of dichlorodimethylsilane and chlorotrimethylsilane. Different grades exist which are characterised by a number indicating the nominal viscosity placed after the name.

Silicone oils used as lubricants have a degree of polymerisation (n = 400 to 1200) such that their kinematic viscosities are nominally between 1000 $mm^2 \cdot s^{-1}$ and 30 000 $mm^2 \cdot s^{-1}$.

CHARACTERS
Appearance
Clear, colourless liquid of various viscosities.

Solubility
Practically insoluble in water and in methanol, very slightly soluble in anhydrous ethanol, miscible with ethyl acetate, with methyl ethyl ketone and with toluene.

IDENTIFICATION
A. Kinematic viscosity at 25 °C (see Tests).

B. Infrared absorption spectrophotometry (*2.2.24*).

Comparison *silicone oil CRS*.

The region of the spectrum from 850-750 cm^{-1} is not taken into account since it may show slight differences depending on the degree of polymerisation.

C. Heat 0.5 g in a test-tube over a small flame until white fumes begin to appear. Invert the tube over a 2nd tube containing 1 mL of a 1 g/L solution of *chromotropic acid, sodium salt R* in *sulfuric acid R* so that the fumes reach the solution. Shake the 2nd tube for about 10 s and heat on a water-bath for 5 min. The solution is violet.

D. In a platinum crucible, prepare the sulfated ash (*2.4.14*) using 50 mg. The white powder obtained gives the reaction of silicates (*2.3.1*).

TESTS
Acidity
To 2.0 g add 25 mL of a mixture of equal volumes of *anhydrous ethanol R* and *ether R*, previously neutralised to 0.2 mL of *bromothymol blue solution R1*, and shake. Not more than 0.15 mL of *0.01 M sodium hydroxide* is required to change the colour of the solution to blue.

Viscosity (*2.2.10*)
Determine the dynamic viscosity at 25 °C. Calculate the kinematic viscosity taking the relative density to be 0.97. The kinematic viscosity is within the range 95 per cent to 105 per cent of the nominal viscosity stated on the label.

Mineral oils
Place 2 mL in a test-tube and examine in ultraviolet light at 365 nm. The fluorescence is not more intense than that of a solution containing 0.1 ppm of *quinine sulfate R* in *0.005 M sulfuric acid* examined in the same conditions.

Phenylated compounds
The refractive index (*2.2.6*) is not greater than 1.410.

Heavy metals
Maximum 5 ppm.

Solvent mixture *dilute ammonia R2*, 2 g/L solution of *hydroxylamine hydrochloride R* (1:9 *V/V*).

Mix 1.0 g with *methylene chloride R* and dilute to 20 mL with the same solvent. Add 1.0 mL of a freshly prepared 0.02 g/L solution of *dithizone R* in *methylene chloride R*, 0.5 mL of *water R* and 0.5 mL of the solvent mixture. At the same time, prepare the reference solution as follows: to 20 mL of *methylene chloride R* add 1.0 mL of a freshly prepared 0.02 g/L solution of *dithizone R* in *methylene chloride R*, 0.5 mL of *lead standard solution (10 ppm Pb) R* and 0.5 mL of the solvent mixture. Immediately shake each solution vigorously for 1 min. Any red colour in the test solution is not more intense than that in the reference solution.

Volatile matter
Maximum 2.0 per cent, determined on 2.00 g by heating in an oven at 150 °C for 24 h. Carry out the test using a dish 60 mm in diameter and 10 mm deep.

LABELLING

The label states:

— the nominal viscosity by a number placed after the name of the product;

— that the contents are to be used as a lubricant.

2. Silicone Elastomer for Closures and Tubing

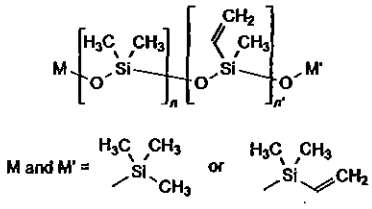
(Ph. Eur. method 3.1.9)

DEFINITION

Silicone elastomer complying with the following requirements is suitable for the manufacture of closures and tubing.

Silicone elastomer is obtained by cross-linking a linear polysiloxane constructed mainly of dimethylsiloxy units with small quantities of methylvinylsiloxy groups; the chain ends are blocked by trimethylsiloxy or dimethylvinylsiloxy groups.

The general formula of the polysiloxane is:



The cross-linking is carried out in the hot state:

— either with:

  — 2,4-dichlorobenzoyl peroxide for extruded products; or

  — 2,4-dichlorobenzoyl peroxide or dicumyl peroxide or *OO*-(1,1-dimethylethyl) *O*-isopropyl monoperoxycarbonate or 2,5-bis[(1,1-dimethylethyl) dioxy]-2,5-dimethylhexane for moulded products;

— or by hydrosilylation by means of polysiloxane with -SiH groups using platinum as a catalyst.

In all cases, appropriate additives are used such as silica and sometimes small quantities of organosilicon additives (α,ω-dihydroxypolydimethylsiloxane).

CHARACTERS

Appearance

Transparent or translucent material.

Solubility

Practically insoluble in organic solvents, some of which, for example cyclohexane, hexane and methylene chloride, cause a reversible swelling of the material.

IDENTIFICATION

A. Infrared absorption spectrophotometry (*2.2.24*) by the multiple reflection method for solids.

Comparison *silicone elastomer CRS.*

B. Heat 1.0 g in a test-tube over a small flame until white fumes begin to appear. Invert the tube over a 2nd tube containing 1 mL of a 1 g/L solution of *chromotropic acid, sodium salt R* in *sulfuric acid R* so that the fumes reach the solution. Shake the 2nd tube for about 10 s and heat on a water-bath for 5 min. The solution is violet.

C. 50 mg of the residue of combustion gives the reaction of silicates (*2.3.1*).

TESTS

If necessary, cut the material into pieces of maximum dimension on a side of not greater than 1 cm.

Solution S

Place 25 g in a borosilicate-glass flask with a ground-glass neck. Add 500 mL of *water R* and boil under a reflux condenser for 5 h. Allow to cool and decant the solution.

Appearance of solution

Solution S is clear (*2.2.1*).

Acidity or alkalinity

To 100 mL of solution S add 0.15 mL of *bromothymol blue solution R1*. Not more than 2.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To a further 100 mL of solution S, add 0.2 mL of *methyl orange solution R*. Not more than 1.0 mL of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator from yellow to orange.

Relative density (*2.2.5*)

1.05 to 1.25, determined using a density bottle with *anhydrous ethanol R* as the immersion liquid.

Reducing substances

To 20 mL of solution S add 1 mL of *dilute sulfuric acid R* and 20 mL of *0.002 M potassium permanganate*. Allow to stand for 15 min. Add 1 g of *potassium iodide R* and titrate immediately with *0.01 M sodium thiosulfate* using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration using 20 mL of *water R* instead of solution S. The difference between the titration volumes is not more than 1.0 mL.

Substances soluble in hexane

Maximum 3 per cent.

Evaporate 25 mL of the solution obtained in the test for phenylated compounds in a glass evaporating dish on a water-bath and dry in an oven at 100-105 °C for 1 h. The residue weighs not more than 15 mg.

Phenylated compounds

Place 2.0 g in a borosilicate-glass flask with a ground-glass neck and add 100 mL of *hexane R*. Boil under a reflux condenser for 4 h. Cool, then filter rapidly through a sintered-glass filter (16) (*2.1.2*). Collect the filtrate and close the container immediately to avoid evaporation.

At wavelengths from 250 nm to 340 nm, the absorbance (*2.2.25*) is not greater than 0.4.

Mineral oils

Place 2 g in a 100 mL conical flask containing 30 mL of a mixture of 5 volumes of *ammonia R* and 95 volumes of *pyridine R*. Allow to stand for 2 h, shaking frequently. Decant the pyridine solution and examine in ultraviolet light at 365 nm. The fluorescence is not greater than that of a solution containing 1 ppm of *quinine sulfate R* in *0.005 M sulfuric acid* examined in the same conditions.

Volatile matter

Maximum 0.5 per cent for silicone elastomer prepared using peroxides; maximum 2.0 per cent for silicone elastomer prepared using platinum.

Weigh 10.0 g of the substance previously stored for 48 h in a desiccator over *anhydrous calcium chloride R*. Heat in an oven at 200 °C for 4 h, allow to cool in a desiccator and weigh again.

Silicone elastomer prepared using peroxides complies with the following additional test:

Residual peroxides

Maximum 0.08 per cent calculated as dichlorobenzoyl peroxide.

Place 5 g in a borosilicate-glass flask, add 150 mL of *methylene chloride R* and close the flask. Stir with a mechanical stirrer for 16 h. Filter rapidly, collecting the

filtrate in a flask with a ground-glass neck. Replace the air in the container with *oxygen-free nitrogen R*, introduce 1 mL of a 200 g/L solution of *sodium iodide R* in *anhydrous acetic acid R*, close the flask, shake thoroughly and allow to stand protected from light for 30 min. Add 50 mL of *water R* and titrate immediately with *0.01 M sodium thiosulfate*, using 0.25 mL of *starch solution R* as indicator. Carry out a blank titration. The difference between the titration volumes is not greater than 2.0 mL.

Silicone elastomer prepared using platinum complies with the following additional test:

Platinum

Maximum 30 ppm.

In a quartz crucible, ignite 1.0 g of the material to be examined, raising the temperature gradually until a white residue is obtained. Transfer the residue to a graphite crucible. To the quartz crucible add 10 mL of a freshly prepared mixture of 1 volume of *nitric acid R* and 3 volumes of *hydrochloric acid R*, heat on a water-bath for 1-2 min and transfer to the graphite crucible. Add 5 mg of *potassium chloride R* and 5 mL of *hydrofluoric acid R* and evaporate to dryness on a water-bath. Add 5 mL of *hydrofluoric acid R* and evaporate to dryness again; repeat this operation twice. Dissolve the residue in 5 mL of *1 M hydrochloric acid*, warming on a water-bath. Allow to cool and add the solution to 1 mL of a 250 g/L solution of *stannous chloride R* in *1 M hydrochloric acid*, rinse the graphite crucible with a few millilitres of *1 M hydrochloric acid* and dilute to 10.0 mL with the same acid.

Prepare simultaneously the reference solution as follows: to 1 mL of a 250 g/L solution of *stannous chloride R* in *1 M hydrochloric acid*, add 1.0 mL of *platinum standard solution (30 ppm Pt) R* and dilute to 10.0 mL with *1 M hydrochloric acid*.

The colour of the test solution is not more intense than that of the standard.

LABELLING

The label states whether the material was prepared using peroxides or platinum.

G. Plastic Additives

(Ph. Eur. method 3.1.13)

DEFINITION

Plastic additives are chemical substances that are intentionally added to plastic materials to achieve a physical or chemical effect during processing of the plastic or in the final material or container. They may consist of a single chemical substance, a polymeric substance or a defined mixture of different components. Additives are intended to be present in the final material or container.

Substances present that have not been added intentionally are considered to be impurities and include reaction and degradation products, which may be limited by a suitable specification.

GENERAL REQUIREMENTS

Each plastic additive and, if likely to be present in the final material or container, its impurities and reaction and degradation products, must be toxicologically qualified, taking into account the maximum potential exposure as a result of leaching into the contents of the container and product contamination.

Acceptance criteria must be specified for the identity, physico-chemical characteristics, impurities and the assay for each component.

A plastic material contains no more than the strict minimum of additives, at the lowest effective concentration for the intended use and to ensure the stability and quality of the final material or container.

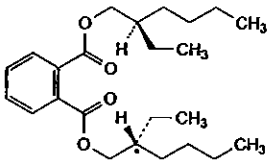
Additives specified for plastic materials described in the European Pharmacopoeia are stated below. Plastic additives other than those described in the Pharmacopoeia may be used subject to agreement on a case-by-case basis by the competent authority.

LIST

NOTE. The nomenclature according to IUPAC rules is given first. The synonym in bold corresponds to the name given in the texts of Chapter 3. The synonym according to Chemical Abstracts (CA) Index rules is also given.

plastic additive 01

$C_{24}H_{38}O_4$. [117-81-7].



its epimer at C* and its enantiomer

bis[(2*RS*)-2-ethylhexyl] benzene-1,2-dicarboxylate

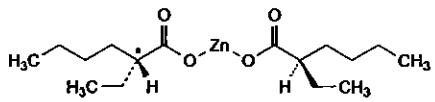
synonyms: — **di(2-ethylhexyl) phthalate,**

— 1,2-benzenedicarboxylic acid, bis(2-ethylhexyl) ester,

— DEHP.

plastic additive 02

$C_{16}H_{30}O_4Zn$. [136-53-8].



its epimer at C* and its enantiomer

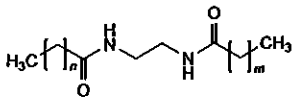
zinc bis[(2*RS*)-2-ethylhexanoate]

synonyms: — **zinc octanoate,**

— hexanoic acid, 2-ethyl, zinc salt (2:1),

— zinc 2-ethylcaproate.

plastic additive 03
[05518-18-3]/[00110-30-5].



N,N′-(ethane-1,2-diyl)dialcanamide (with *n* and *m* = 14 or 16)

synonyms: — ***N,N′*-diacylethylenediamines,**

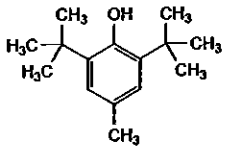
— *N,N′*-diacylethylenediamine (in this context acyl means in particular palmitoyl and stearoyl).

plastic additive 04
[8013-07-8].
epoxidised soya oil

plastic additive 05
[8016-11-3].
epoxidised linseed oil

plastic additive 06
[57455-37-5](TSCA)/[101357-30-6] (EINECS)/Pigment blue 29 (CI 77007)
ultramarine blue

plastic additive 07
$C_{15}H_{24}O$. [128-37-0]



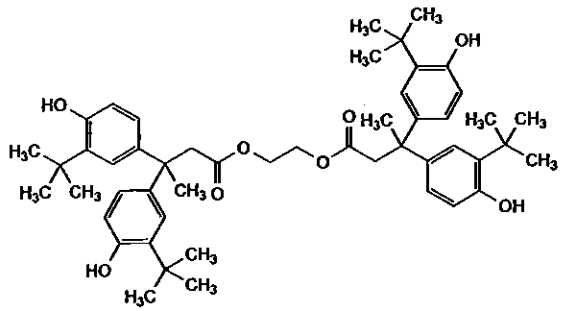
2,6-di-*tert*-butyl-4-methylphenol

synonyms: — **butylhydroxytoluene,**

— phenol, 2,6-bis(1,1-dimethylethyl)-4 methyl-

— 2,6-bis(1,1-dimethylethyl)-4-methylphenol.

plastic additive 08
$C_{50}H_{66}O_8$. [32509-66-3].



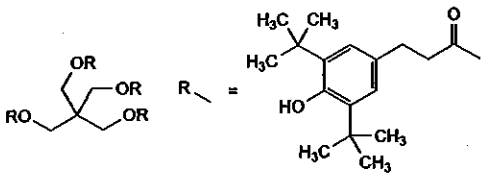
ethane-1,2-diyl bis[3,3-bis(3-*tert*-butyl-4-hydroxyphenyl)butanoate]

synonyms: — **ethylene bis[3,3-bis[3-(1,1-dimethylethyl)-4-hydroxyphenyl] butanoate],**

— benzenepropanoic acid, 3-(1,1-dimethylethyl)-β-[3-(1,1-dimethylethyl)-4-hydroxyphenyl]-4-hydroxy-β-methyl-, 1,1′-(1,2-ethanediyl) ester,

— ethylene bis[3,3-bis(3-*tert*-butyl-4-hydroxyphenyl)butyrate].

plastic additive 09
$C_{73}H_{108}O_{12}$. [6683-19-8].



2,2-bis[[[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propanoyl]oxy] methyl]propan-1,3-diyl bis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propanoate]

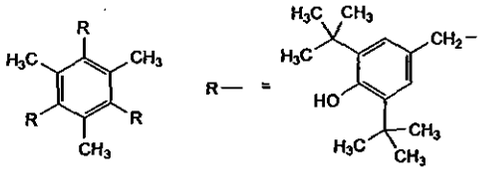
synonyms: — **pentaerythrityl tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate],**

— benzenepropanoic acid, 3,5-bis(1,1-dimethylethyl)-4-hydroxy-, 1,1′-[2,2-bis[[3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]-1-oxopropoxy]methyl]-1,3-propanediyl] ester,

— 2,2-bis[[[3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]propanoyl]oxy]methyl] propane-1,3-diyl 3-[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]propanoate,

— 2,2-bis(hydroxymethyl)propane-1,3-diol tetrakis[3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate].

plastic additive 10
$C_{54}H_{78}O_3$. [1709-70-2].



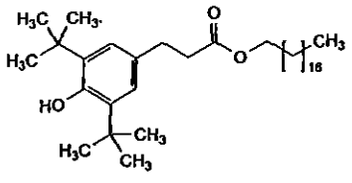
4,4′,4″-[(2,4,6-trimethylbenzene-1,3,5-triyl)tris (methylene)]tris(2,6-di-*tert*-butylphenol)

synonyms: — **2,2′,2″,6,6′,6″-hexa-*tert*-butyl-4,4′,4″-[(2,4,6-trimethyl-1,3,5-benzenetriyl) trismethylene]triphenol,**

— phenol, 4,4′,4″-[(2,4,6-trimethyl-1,3,5-benzenetriyl)tris(methylene)]tris[2,6- bis(1,1-dimethylethyl)-,

— 1,3,5-tris[3,5-di-*tert*-butyl-4-hydroxybenzyl]-2,4,6-trimethylbenzene.

plastic additive 11
$C_{35}H_{62}O_3$. [2082-79-3].

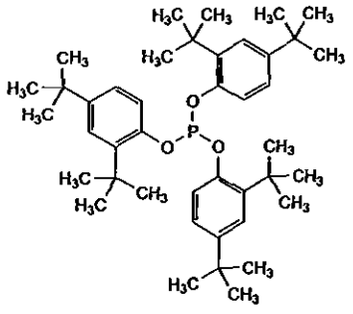


octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propanoate

synonyms: — **octadecyl 3-(3,5-di-*tert*-butyl-4-hydroxyphenyl)propionate,**

— benzenepropanoic acid, 3,5-bis(1,1-dimethylethyl)-4-hydroxy-, octadecyl ester.

plastic additive 12
$C_{42}H_{63}O_3P$. [31570-04-4].



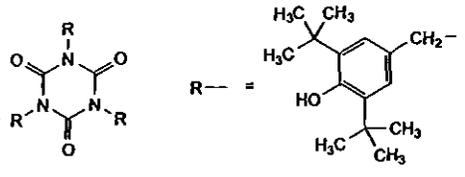
tris(2,4-di-*tert*-butylphenyl) phosphite

synonyms: — **tris(2,4-di-*tert*-butylphenyl) phosphite,**

— phenol, 2,4-bis(1,1-dimethylethyl)-, 1,1′,1″-phosphite,

— 2,4-bis(1,1-dimethylethyl)phenyl, phosphite.

plastic additive 13
$C_{48}H_{69}N_3O_6$. [27676-62-6].



1,3,5-tris[(3,5-di-*tert*-butyl-4-hydroxyphenyl)methyl]-1,3,5-triazine-2,4,6(1*H*,3*H*,5*H*)-trione

bis[(2*RS*)-2-ethylhexyl] benzene-1,4-dicarboxylate

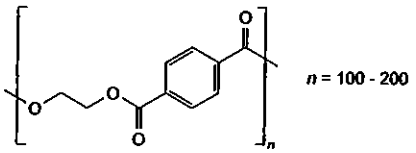
synonyms: — **bis(2-ethylhexyl) terephthalate,**

— 1,4-benzenedicarboxylic acid,

— 1,4-bis(2-ethylhexyl) ester.

H. Polyethylene Terephthalate for Containers for Preparations not for Parenteral Use

(Ph. Eur. method 3.1.15)



DEFINITION

Polyethylene terephthalate is obtained from the polymerisation of terephthalic acid or dimethyl terephthalate with ethylene glycol. Isophthalic acid, dimethyl isophthalate, 1,4-bis(hydroxymethyl)cyclohexane (cyclohexane-1,4-dimethanol) or diethylene glycol may be used in the polymerisation. It may contain not more than 0.5 per cent of silica or silicates and colouring matter approved by the competent authority.

PRODUCTION

The manufacturing process is validated to demonstrate that the residual acetaldehyde content is not greater than 10 ppm in the granules.

CHARACTERS

Appearance

Clear or opaque granules.

Solubility

Practically insoluble in water, in ethanol (96 per cent) and in methylene chloride. It is hydrolysed by strong bases.

IDENTIFICATION

A. Place 0.10 g of the material to be examined into a borosilicate glass flask with a ground-glass neck. Add 25 mL of a 200 g/L solution of *potassium hydroxide R* in a 50 per cent *V/V* solution of *anhydrous ethanol R*. Reflux for 30 min. Allow to cool and dilute to 100 mL with *water R*. Filter if necessary. Dilute 1.0 mL of the filtrate to 100 mL with *water R*. Examined between 210 nm and 330 nm (*2.2.25*), the solution shows an absorption maximum at 240 nm.

B. Dissolve 0.05 g of the material to be examined in 2 mL of *1,1,1,3,3,3-hexafluoropropan-2-ol R*. Apply to a glass plate on a water-bath in a fume cupboard several drops of the solution to produce a film of about 15 mm by 15 mm. Allow the solvent to evaporate and remove the film using a stream of water and a scraper. Dry in an oven at 100-105 °C for 1-2 h. Examine the film by infrared absorption spectrophotometry (*2.2.24*). The spectrum of the material to be examined shows maxima in particular at 1725 cm^{-1}, 1410 cm^{-1}, 1265 cm^{-1}, 1120 cm^{-1}, 1100 cm^{-1}, 1020 cm^{-1}, 875 cm^{-1}, 725 cm^{-1}. The spectrum obtained, in addition, is identical to that of the material selected for the type sample.

TESTS

If necessary, cut out samples for testing to a maximum size of 1 cm per side.

Solution S1

Place 10.0 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 200 mL of *water R* and heat at 50 °C for 5 h. Allow to cool and decant the solution. *Use solution S1 within 4 h of its preparation.*

Solution S2

Place 10 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 100 mL of *ethanol (96 per cent) R* and heat at 50 °C for 5 h. Allow to cool and decant the solution. *Use solution S2 within 4 h of its preparation.*

Solution S3

Place 20 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 50 mL of *0.1 M hydrochloric acid* and heat at 50 °C for 5 h. Allow to cool and decant the solution. *Use solution S3 within 4 h of its preparation.*

Solution S4

Place 20 g of the material to be examined into a borosilicate glass flask with a ground-glass neck. Add 50 mL of *0.01 M sodium hydroxide* and heat at 50 °C for 5 h. Allow to cool and decant. *Use solution S4 within 4 h of its preparation.*

Appearance of solution S1

Solution S1 is clear (*2.2.1*).

Appearance of solution S2

Solution S2 is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity

To 50 mL of solution S1 add 0.15 mL of *BRP indicator solution R*. The solution turns yellow. Not more than 0.5 mL of *0.01 M sodium hydroxide* is required to change the colour of the indicator to blue. To another 50 mL of solution S1 add 0.2 mL of *methyl orange solution R*. The solution turns yellow. Not more than 0.5 mL of *0.01 M hydrochloric acid* is required to reach the beginning of the colour change of the indicator to orange.

Absorbance of solution S1 (*2.2.25*)

Maximum 0.20 between 220 nm and 340 nm. In addition, for coloured polyethylene terephthalate: maximum 0.05 between 400 nm to 800 nm.

Absorbance of solution S2 (*2.2.25*)

Maximum 0.05 between 400 nm and 800 nm.

Reducing substances

Add 2 mL of *0.5 M sulfuric acid* and 20.0 mL of *0.002 M potassium permanganate* to 20.0 mL of solution S1. Boil for 3 min. Cool immediately to ambient temperature. Add 1 g of *potassium iodide R*, 0.25 mL of *starch solution R* as indicator and titrate with *0.01 M sodium thiosulfate*. Perform a blank titration using 20.0 mL of *water R*. The difference in volume used in the 2 titrations is not greater than 0.5 mL.

Substances soluble in dioxan

Maximum 3 per cent.

Place 2 g of the material to be examined in a borosilicate glass flask with a ground-glass neck. Add 20 mL of *dioxan R* and heat under reflux for 2 h. Evaporate 10 mL of the solution to dryness on a water-bath and then dry the residue at 100-105 °C. The residue weighs a maximum of 30 mg.

Extractable aluminium

Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S3.

Reference solutions Prepare the reference solutions using *aluminium standard solution (200 ppm Al) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength 396.15 nm, the spectral background being taken at 396.25 nm.

Verify the absence of aluminium in the *0.1 M hydrochloric acid* used.

Extractable antimony
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S4.

Reference solutions Prepare the reference solutions using *antimony standard solution (100 ppm Sb) R*, diluting with *0.01 M sodium hydroxide*.

Wavelength 231.15 nm or 217.58 nm, the spectral background being taken at 231.05 nm.

Extractable barium
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S3.

Reference solutions Prepare the reference solutions using *barium standard solution (50 ppm Ba) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength 455.40 nm, the spectral background being taken at 455.30 nm.

Verify the absence of barium in the *0.1 M hydrochloric acid* used.

Extractable cobalt
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S3.

Reference solutions Prepare the reference solutions using *cobalt standard solution (100 ppm Co) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength 228.62 nm, the spectral background being taken at 228.50 nm.

Verify the absence of cobalt in the *0.1 M hydrochloric acid* used.

Extractable germanium
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S4.

Reference solutions Prepare the reference solutions using *germanium standard solution (100 ppm Ge) R*, diluting with *0.01 M sodium hydroxide*.

Wavelength 206.87 nm or 265.12 nm, the spectral background being taken at 206.75 nm.

Extractable manganese
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S3.

Reference solutions Prepare the reference solutions using *manganese standard solution (100 ppm Mn) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength 257.61 nm, the spectral background being taken at 257.50 nm.

Verify the absence of manganese in the *0.1 M hydrochloric acid* used.

Extractable titanium
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S3.

Reference solutions Prepare the reference solutions using *titanium standard solution (100 ppm Ti) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength 323.45 nm or 334.94 nm, the spectral background being taken at 323.35 nm.

Verify the absence of titanium in the 0.1M hydrochloric acid used.

Extractable zinc
Maximum 1 ppm.

Inductively coupled plasma-atomic emission spectrometry (*2.2.57*).

Test solution Solution S3.

Reference solutions Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluting with *0.1 M hydrochloric acid*.

Wavelength 213.86 nm, the spectral background being taken at 213.75 nm.

Verify the absence of zinc in the *0.1 M hydrochloric acid* used.

Sulfated ash (*2.4.14*)
Maximum 0.5 per cent determined on 1.0 g.

Appendix XXI

A. Abbreviated Titles

In accordance with the General Notices the main title of each monograph may be abbreviated using the following abbreviations. An abbreviated title has the same significance as the main title.

Cations

Alum.	Aluminium
Ammon.	Ammonium
Bism.	Bismuth
Calc.	Calcium
Ferr.	Ferrous
Mag.	Magnesium
Pot.	Potassium
Sod.	Sodium

Anions

Acet.	Acetate
Benz.	Benzoate
Brom.	Bromide
Chlor.	Chloride
Cit.	Citrate
Dihydrochlor.	Dihydrochloride
Fumar.	Fumarate
Hydrobrom.	Hydrobromide
Hydrochlor.	Hydrochloride
Hydrox.	Hydroxide
Iod.	Iodide
Lact.	Lactate
Mal.	Maleate
Methonit.	Methonitrate
Methylsulf.	Methylsulfate
Metilsulf.	Metilsulfate
Nit.	Nitrate
Ox.	Oxide
Phenylprop.	Phenylpropionate
Phos.	Phosphate
Prop.	Propionate
Succin.	Succinate
Sulf.	Sulfate
Tart.	Tartrate

Adjectives

Ammon.	Ammoniated
Arom.	Aromatic
Camph.	Camphorated
Co.	Compound
Conc.	Concentrated
Cryst.	Crystalline
Efferv.	Effervescent
Emulsif.	Emulsifying
Liq.	Liquefied; Liquid
Prep.	Prepared
Simp.	Simple

Preparations

Applic.	Application
Caps.	Capsules
Ext.	Extract
Inf.	Infusion
Inj.	Injection
Lin.	Liniment
Lot.	Lotion
Mixt.	Mixture
Oint.	Ointment
Pess.	Pessaries
Soln.	Solution
Suppos.	Suppositories
Tabs.	Tablets
Tinct.	Tincture

B. Approved Synonyms

Where the English title at the head of a monograph in the European Pharmacopoeia is different from that at the head of the text incorporated into the British Pharmacopoeia or the British Pharmacopoeia (Veterinary), an Approved Synonym (or Approved Synonyms) is created on the recommendation of the British Pharmacopoeia Commission.

In accordance with the General Notice on Titles, the name or names given in the right-hand column of the list below are Approved Synonyms for the name at the head of the monograph of the European Pharmacopoeia given in the left-hand column. Where there is more than one entry in the right-hand column, the first entry is used as the title of the monograph in the British Pharmacopoeia or the British Pharmacopoeia (Veterinary) and the remaining entries are included as subsidiary titles.

Approved Synonyms and subsidiary titles have the same significance as the main title and are thus official titles.

Names made by changing the order of the words in an Approved Synonym, with the addition of a preposition when necessary, are also Approved Synonyms.

Where square brackets are used in a title these may be replaced by round brackets, and *vice versa*. The words 'per cent' may be replaced by the symbol '%'.

Where the word 'Injection' appears in the title or synonym of a monograph in the European Pharmacopoeia, the abbreviation 'Inj.' is declared to be an Approved Synonym for that part of the title.

Monographs included in the British Pharmacopoeia (Veterinary) are identified by means of a superscript number:[1].

Anhydrous Sodium Sulfate	Natrium Sulfuricum
Valerian Root	Valeriana
Zinc Sulfate	Zincum Sulfuricum

C. Eye drops

Codes for eye drops in single-dose containers

The following codes are approved for use on single unit doses of eye drops where the individual container may be too small to bear all of the appropriate labelling information (see the general monograph for Eye Drops).

The inclusion of a preparation in this list does not necessarily mean that a monograph is or will be included in the *British Pharmacopoeia*.

Eye Drops	Code	Eye Drops	Code
Adrenaline / Epinephrine	ADN / EPN	Lidocaine and Fluorescein	LIDFLN
Apraclonidine	ACD	Metipranolol	MPR
Atropine Sulfate	ATR	Moxisylyte	MOX
Betamethasone	BET	Neomycin	NEO
Carbachol	CAR	Oxybuprocaine	OXB
Castor Oil	CASOIL	Phenylephrine	PHNL
Chloramphenicol	CPL	Phenylephrine and Cyclopentolate	PHNCYC
Cocaine	CCN	Pilocarpine	PIL
Cyclopentolate	CYC	Povidone-Iodine	PVI
Diclofenac	DICL	Prednisolone	PRED
Fluorescein	FLN	Proxymetacaine	PROX
Dexamethasone Sodium Phosphate	DSP	Proxymetacaine and Fluorescein	PROXFLN
Gentamicin	GNT	Rose Bengal	ROS
Homatropine	HOM	Sodium Chloride	SALINE[1]
Hydrocortisone	HCOR	Sodium Cromoglicate	SCG
Hydroxyethylcellulose and Sodium Chloride	HECL	Sulfacetamide	SULF
		Tetracaine	TET
Hyoscine	HYO	Timolol	TIM
Hypromellose	HPRM	Tropicamide	TRO
Lachesine	LAC	Zinc Sulfate	ZSU

[1] The term 'Saline' indicates the contents of the container are a 0.9% w/v solution of Sodium Chloride.

Appendix XXII

A. Viral Safety

(Ph. Eur. general texts 5.1.7)

This chapter provides general requirements concerning the viral safety of medicinal products whose manufacture has involved the use of materials of human or animal origin. Since viral safety is a complex issue, it is important that a risk assessment is carried out. Requirements to be applied to a specific medicinal product are decided by the competent authority.

Where the risk of viral contamination exists, complementary measures are used as appropriate to assure the viral safety of medicinal products, based on:

- selection of source materials and testing for viral contaminants;
- testing the capacity of the production process to remove and/or inactivate viruses;
- testing for viral contamination at appropriate stages of production.

Where appropriate, one or more validated procedures for removal or inactivation of viruses are applied.

Further detailed recommendations on viral safety, including validation studies, are provided, in particular, by the *Note for guidance on virus validation studies: the design, contribution and interpretation of studies validating the inactivation and removal of viruses (CPMP/BWP/268/95)* of the Committee for Proprietary Medicinal Products, and the *ICH guideline Q5A: Viral safety evaluation of biotechnology products derived from cell lines of human or animal origin* (including any subsequent revisions of these documents).

Requirements concerning immunological products for veterinary use are dealt with in the monographs *Vaccines for veterinary use (0062)* and *Immunosera for veterinary use (0030)* and related general chapters.

Risk assessment

A risk assessment with respect to viral safety is carried out where materials of human or animal origin are used as ingredients of medicinal products or in the manufacture of active substances, excipients or medicinal products.

The principle of the risk assessment is to consider various factors that may influence the potential level of infectious particles in the medicinal product and factors related to the use of the medicinal product that determine or influence the viral risk to the recipients.

The risk assessment takes into consideration relevant factors, for example:

- the species of origin;
- the organ, tissue, fluid of origin;
- the potential contaminants in view of the origin of the raw material and the history of the donor(s), preferably including epidemiological data;
- the potential contaminants from the manufacturing process (for example, from risk materials used during manufacture);
- the infectivity and pathogenicity of the potential contaminants for the intended recipients of the medicinal product, taking account of the route of administration of the medicinal product;
- the amount of material used to produce a dose of medicinal product;
- controls carried out on the donor(s), on the raw material, during production and on the final product;
- the manufacturing process of the product and its capacity to remove and/or inactivate viruses.

The risk assessment can be based mainly on the manufacturing conditions if these include rigorous inactivation steps (for example, for gelatin etc., and products terminally sterilised by steam or dry heat as described in the general texts on sterility (*5.1*)).

B. Minimising the Risk of Transmitting Animal Spongiform Encephalopathy Agents Via Human and Veterinary Medicinal Products

(Ph. Eur. general texts 5.2.8)

This chapter is identical with the Note for Guidance on Minimising the Risk of Transmitting Animal Spongiform Encephalopathy Agents via Human and Veterinary Medicinal Products – Revision 3, (EMA/410/01 rev. 3).

CONTENTS

1. INTRODUCTION

6-8. Amino acids
6-9. Peptones

1 INTRODUCTION

1-1 SCIENTIFIC BACKGROUND

Transmissible Spongiform Encephalopathies (TSEs) are chronic degenerative nervous diseases characterised by the accumulation of an abnormal isoform of a cellular glycoprotein (known as PrP or prion protein). The abnormal

isoform of PrP (PrP^{TSE}) differs from normal PrP (PrPc) in being highly resistant to protease and heat denaturation treatments. PrP^{TSE} is considered to be the infective agent responsible for transmitting TSE disease.

TSE diseases in animals include:
- bovine spongiform encephalopathy (BSE) in cattle,
- scrapie in sheep and goats,
- chronic wasting disease (CWD) in cervids (deer and elk),
- transmissible mink encephalopathy (TME) in farmed mink,
- feline spongiform encephalopathy (FSE) in felids (specifically domestic cats and captive large cats), and
- spongiform encephalopathy of exotic ungulates in zoos.

In humans, spongiform encephalopathies include different forms of Creutzfeldt-Jakob Disease (CJD), Kuru, Gerstmann-Sträussler-Scheinker Syndrome (GSS), and Fatal Familial Insomnia (FFI).

Iatrogenic transmission of spongiform encephalopathies has been reported. In sheep, scrapie has been accidentally transmitted by the use of Louping Ill vaccine prepared from pooled, formaldehyde treated ovine brain and spleen in which material from scrapie-infected sheep had been inadvertently incorporated. Also, transmission of scrapie to sheep and goats occurred following use of a formol-inactivated vaccine against contagious agalactia, prepared with brain and mammary gland homogenates of sheep infected with *Mycoplasma agalactiae.* In man, cases of transmission of CJD have been reported which have been attributed to the parenteral administration of growth hormone and gonadotropin derived from human cadaveric pituitary glands. Cases of CJD have also been attributed to the use of contaminated instruments in brain surgery and with the transplantation of human dura mater and cornea.

Interspecies TSE transmission is restricted by a number of natural barriers, transmissibility being affected by the species of origin, the prion strain, dose, route of exposure and, in some species, the host allele of the PRNP gene. Species barriers can be crossed under appropriate conditions.

BSE was first diagnosed in the United Kingdom in 1986 and a large number of cattle and individual herds have been affected. It is clear that BSE is a food borne disease associated with feed (e.g. meat and bone meal) derived from TSE affected animals. Other countries have experienced cases of BSE, either in animals imported from the United Kingdom or in indigenous animals. There is convincing evidence to show that the variant form of CJD (vCJD) is caused by the agent which is responsible for BSE in cattle. Therefore, a cautious approach continues to be warranted if biological materials from species naturally affected by TSE diseases, especially bovine species, are used for the manufacture of medicinal products.

In the course of active surveillance programs, two previously unrecognized forms of atypical BSE (BSE-L, also named BASE, and BSE-H) have been identified in rare sporadic cases from Europe, North America, and Japan. The 'L' and 'H' identify the higher and lower electrophoretic positions of their protease-resistant PrP^{TSE} isoforms. It is noteworthy that atypical cases have been found in countries that did not experience classical BSE so far, like Sweden, or in which only few classical BSE cases have been found like Canada or USA. The atypical BSE agent has been experimentally transmitted to transgenic mice expressing the human prion protein and to a cynomolgus monkey.

Scrapie occurs worldwide and has been reported in most European countries. It has the highest incidence in Cyprus.

While humans have been exposed to naturally occurring scrapie for over 250 years, there is no epidemiological evidence directly linking scrapie to spongiform encephalopathies in humans[1]. However, there remains a theoretical and currently unquantifiable risk that some BSE-contaminated protein supplement may have been fed to sheep. Further, it should also be assumed that any BSE agent introduced into the small ruminant population via contaminated feed is likely to be recycled and amplified[2].

There is interest in infecting cells with TSE agents to develop assays and for basic scientific reasons. Some success has been reported, usually but not always with neural cell lines. The conditions needed to infect a cell are not well understood and the process is difficult requiring particular combinations of agent and cell. It is not considered appropriate to make specific recommendations in terms of cell substrates to be used for production of biological/biotechnology-derived substances. Nevertheless, the possibility of infection of cell lines with TSE agents should be taken into account in risk assessments.

1-2 REGULATORY COMPLIANCE

Risk assessment

Since the use of animal-derived materials is unavoidable for the production of some medicinal products and that complete elimination of risk at source is rarely possible, the measures taken to manage the risk of transmitting animal TSEs via medicinal products represent risk minimisation rather than risk elimination. Consequently, the basis for regulatory compliance should be based on a risk assessment, taking into consideration all pertinent factors as identified in this chapter (see below).

Legal basis

The note for guidance is published by the European Commission following
- Annex I, part I, module 3, section 3.2: *Content: basic principles and requirements*, point (9) of Directive 2001/83/EC of the European Parliament and of the Council of 6 November 2001 on the Community code relating to medicinal products for human use[3], as amended, and
- Annex I, Title I, part 2, section C *Production and control of starting material* of Directive 2001/82/EC of the European Parliament and of the Council of 6 November 2001 on the Community code relating to veterinary medicinal products[4], as amended.

These directives require that applicants for marketing authorisation for human and veterinary medicinal products must demonstrate that medicinal products are manufactured in accordance with the latest version of this note for guidance published in the *Official Journal of the European Union.* This is a continuing obligation after the marketing authorisation has been granted.

By definition, the principle of Specified Risk Materials as defined in Regulation (EC) No 999/2001 of the European Parliament and of the Council[5] does not apply to medicinal

[1] *This is currently being assessed by EFSA and ECDC. For updated information, please refer to the following link: http://registerofquestions.efsa.europa.eu/roqFrontend/questionsListLoader?mandate=M-2009-0221*

[2] *In January 2005, after confirmation of BSE in a goat in France, additional legislative measures were taken related to monitoring and an increased testing of small ruminants. The increased surveillance did not identify additional cases of BSE in sheep and goats in the EU.*

[3] *OJ L 311, 28.11.2001, p. 67.*

[4] *OJ L 311, 28.11.2001, p. 1.*

[5] *OJ L 147, 31.5.2001, p. 1.*

products. However, Regulation (EC) No 1774/2002 of the European Parliament and of the Council[6], which applies since 1st May 2003, lays down health rules concerning animal by-products not intended for human consumption. As a general rule, and unless properly justified, all animal by-products used as starting materials in the manufacture of medicinal products should be 'Category 3 (i.e. safe) materials or equivalent', as defined in Regulation (EC) No 1774/2002. Justification for the use of substances derived from other, high infectivity materials must follow an appropriate benefit/risk evaluation (see further below).

The note for guidance should be read in conjunction with the various EU legal instruments including Commission decisions progressively implemented since 1991. Where appropriate, references to these decisions are given in the text. Position statements and explanatory notes made by the Committee for Medicinal Products for Human Use (CHMP) and Committee for Medicinal Products for Veterinary Use (CVMP) are still applicable for the purpose of regulatory compliance unless otherwise superseded by the note for guidance.

The general monograph *Products with risk of transmitting agents of animal spongiform encephalopathies* of the European Pharmacopoeia refers to this chapter, which is identical with the note for guidance. The monograph forms the basis for issuing Certificates of Suitability as a procedure for demonstrating TSE compliance for substances and materials used in the manufacture of human and veterinary medicinal products.

Clarification of note for guidance

As the scientific understanding of TSEs, especially the pathogenesis of the diseases, is evolving, from time to time CHMP and its Biologics Working Party in collaboration with CVMP and its Immunologicals Working Party may be required in the future to develop supplementary guidance in the form of position statements or explanatory notes for the purpose of clarifying the note for guidance.

The supplementary guidance shall be published by the Commission and on the website of the European Medicines Agency and taken into consideration accordingly in the scope of the certification of the European Directorate for the Quality of Medicines & HealthCare (EDQM).

2 SCOPE

TSE-RELEVANT ANIMAL SPECIES

Cattle, sheep, goats and animals that are naturally susceptible to infection with transmissible spongiform encephalopathy agents or susceptible to infection through the oral route other than humans[7] and non-human primates are defined as "TSE-relevant animal species"[8].

MATERIALS

This chapter is concerned with materials derived from "TSE-relevant animal species" that are used for the preparation of:

— active substances,

— excipients and adjuvants, and

— raw and starting materials and reagents used in production (e.g. bovine serum albumin, enzymes, culture media including those used to prepare working cell banks, or new master cell banks for medicinal products which are subject to a new marketing authorisation).

This chapter is also applicable to materials that come into direct contact with the equipment used in manufacture of the medicinal product or that come in contact with the medicinal product and therefore have the potential for contamination.

Materials used in the qualification of plant and equipment, such as culture media used in media fill experiments to validate the aseptic filling process, shall be considered in compliance with this chapter provided that the constituent or constituents are derived from tissues with no detectable infectivity (category IC tissues), where the risk of cross-contamination with potentially infective tissues has been considered (see section 3-3) and where the materials are sourced from countries with negligible BSE risk or controlled BSE risk (Categories A and B, respectively – see section 3-2). Such information shall be provided in the dossier for a marketing authorisation and verified during routine inspection for compliance with Good Manufacturing Practice (GMP).

Other materials such as cleaning agents, softeners and lubricants that come into contact with the medicinal product during its routine manufacture or in the finishing stage or in the primary packaging are considered in compliance with this chapter if they are tallow derivatives prepared using the rigorous physicochemical processes as described in section 6.

SEED LOTS, CELL BANKS AND ROUTINE FERMENTATION/PRODUCTION[9]

For the purpose of regulatory compliance, master seeds or master cell banks in marketing authorisation applications lodged after 1 July 2000 (for human medicinal products) or 1 October 2000 (for veterinary medicinal products) shall be covered by the note for guidance.

Master seeds and master cell banks,

— for vaccine antigens,

— for a biotechnology-derived medicinal product as described in the Annex to Regulation (EC) No 726/2004 of the European Parliament and of the Council[10], and

— for other medicinal products using seed lots or cell banking systems in their manufacture,

that have already been approved for the manufacture of a constituent of an authorised medicinal product shall be considered in compliance with the note for guidance even if they are incorporated in marketing authorisation applications lodged after 1 July 2000 (for human medicinal products) or 1 October 2000 (for veterinary medicinal products).

Master cell banks and master seeds established before 1 July 2000 (for human medicinal products) or 1 October 2000 (for veterinary medicinal products), but not yet approved as a constituent of an authorised medicinal product shall demonstrate that they fulfil the requirements of the note for guidance. If, for some raw or starting materials or reagents used for the establishment of these cell banks or seeds, full documentary evidence is no longer available, the

[6] *OJ L 273, 10.10.2002, p. 1. Regulation (EC) 1774/2002 has been repealed by Regulation (EC) 1069/2009 that will apply from 4 March 2011 (OJ L 300, 14.11.2009, p. 1).*

[7] *Regulatory guidance and position papers have been issued by the Committee for Medicinal Products for Human Use and its Biologics Working Party on human tissue derived medicinal products in relation to CJD and vCJD. Such guidance can be found on http://www.ema.europa.eu*

[8] *Pigs and birds, which are animal species of particular interest for the production of medicinal products, are not naturally susceptible to infection via the oral route. Therefore they are not TSE-relevant animal species within the meaning of this chapter. Also dogs, rabbits and fish are non TSE-relevant animal species within the meaning of this chapter.*

[9] *See also: Position paper on the assessment of the risk of transmission of animal spongiform encephalopathy agents by master seed materials used in the production of veterinary vaccines (EMEA/CVMP/019/01-February 2001 adopted by the Committee for Medicinal Products for Veterinary Use (CVMP) in July 2001, (OJ C 286, 12.10.2001, p. 12)).*

[10] *OJ L 136, 30.4.2004, p. 1.*

applicant should present a risk assessment as described in Section 4 of the note for guidance.

Established working seeds or cell banks used in the manufacture of medicinal products authorised before 1 July 2000 (human medicines) or 1 October 2000 (veterinary medicines), which have been subjected to a properly conducted risk assessment by a Competent Authority of the Member States or the European Medicines Agency and declared to be acceptable, shall also be considered compliant.

However, where materials derived from the "TSE-relevant animal species" are used in fermentation/routine production processes or in the establishment of working seeds and working cell banks, the applicant must demonstrate that they fulfil the requirements of the note for guidance.

3 GENERAL CONSIDERATIONS

3-1 SCIENTIFIC PRINCIPLES FOR MINIMISING RISK

When manufacturers have a choice, the use of materials from "non TSE-relevant animal species" or non-animal origin is preferred. The rationale for using materials derived from "TSE-relevant animal species" instead of materials from "non-TSE-relevant species" or of non-animal origin should be given. If materials from "TSE-relevant animal species" have to be used, consideration should be given to all the necessary measures to minimise the risk of transmission of TSE.

Readily applicable diagnostic tests for TSE infectivity *in vivo* are not yet available. Diagnosis is based on post-mortem confirmation of characteristic brain lesions by histopathology and/or detection of PrP^{TSE} by Western blot or immunoassay. The demonstration of infectivity by the inoculation of suspect tissue into target species or laboratory animals is also used for confirmation. However, due to the long incubation periods of all TSEs, results of *in vivo* tests are available only after months or years.

Several immunochemical tests have been developed for the detection of PrP^{TSE} in post-mortem samples and some are now considered to be extremely sensitive. However, their ability to detect an infected animal depends on the timing of sample collection in relation to timing of exposure, the type of tissue collected and infectious dose acquired, together with consequential timing of onset of clinical disease. There is currently insufficient information on how this might be affected by strain variations.

Although screening of source animals by *in vitro* tests may prevent the use of animals at late stages of incubation of the disease and may provide information about the epidemiological status of a given country or region, none of the tests are considered suitable to unambiguously confirm the negative status of an animal.

Minimising the risks of transmission of TSE is based upon three complementary parameters:

— the source animals and their geographical origin,
— nature of animal material used in manufacture and any procedures in place to avoid cross-contamination with higher risk materials,
— production process(es) including the quality assurance system in place to ensure product consistency and traceability.

3-2 ANIMAL SOURCE

The source materials used for the production of materials for the manufacture of medicinal products shall be derived from animals fit for human consumption following ante- and post-mortem inspection in accordance with EU or equivalent (third country) conditions, except for materials derived from live animals, which should be found healthy after clinical examination.

3-2-1 Geographical sourcing

3-2-1-1 Bovine materials

The World Organisation for Animal Health (OIE)[11] lays down the criteria for the assessment of the status of countries in the chapter of the International Animal Health Code on bovine spongiform encephalopathy. Countries or regions are classified as follows:

A. countries or regions with a negligible BSE risk;
B. countries or regions with a controlled BSE risk;
C. countries or regions with an undetermined BSE risk.

As stipulated in Commission Regulation (EC) No 999/2001, as amended[12], the classification of countries or regions thereof according to their BSE risk, based on the rules laid down by OIE, is legally binding in the EU since 1 July 2007. Commission Decision 2007/453/EC[13] as amended, provides the classification of countries or regions according to their BSE risk.

Previously, the European Commission Scientific Steering Committee (SSC)[14] had established a temporary system for classifying the countries according to their geographical BSE risk (GBR)[15].

For the purposes of this chapter the BSE classification based on the OIE rules should be used. If a country, which was previously classified in accordance to the SSC GBR criteria, has not been classified yet according to the OIE rules, the GBR classification can be used until OIE classification has taken place, provided that there is no evidence of significant change in its BSE risk[16].

Where there is a choice, animals should be sourced from countries with the lowest possible BSE risk (negligible BSE risk countries (Category A)) unless the use of material from countries with a higher BSE risk is justified. Some of the materials identified in Section 6, "Specific Conditions" can be sourced from countries with controlled BSE risk (Category B) and, in some cases, from countries with

---

[12] *Regulation (EC) No 722/2007 (OJ L 164, 26.6.2007, p. 7)*

[13] *OJ L 172, 30.6.2007, p. 84*

[14] *The Scientific Steering Committee established by Commission Decision 97/404/EC (OJ L 169, 27.6.1997, p. 85) shall assist the Commission to obtain the best scientific advice available on matters relating to consumer health. Since May 2003, its tasks have been taken over by the European Food Safety Authority (EFSA): http://www.efsa.europa.eu*

[15] *The European Scientific Steering Committee classification for geographical BSE risk (GBR) gives an indication of the level of likelihood of the presence of one or more cattle clinically or pre-clinically infected with BSE in a given country or region. A definition of the four categories is provided in the following Table.*

GBR level	Presence of one or more cattle clinically or pre-clinically infected with BSE in a geographical region/country
I	Highly unlikely
II	Unlikely but not excluded
III	Likely but not confirmed or confirmed at a lower level
IV	Confirmed at a higher level (≥ 100 cases/1 Million adult cattle per year)

Reports of the GBR assessment of the countries are available on the SSC website (http://ec.europa.eu/food/fs/sc/ssc/outcome_en.html)

[16] *Experts consider that the GBR classification system is stable enough, so that it can continue to be used, during the interim period, for the demonstration of compliance with this chapter.*

undetermined BSE risk (Category C), provided that the controls and requirements as specified in the relevant sections below are applied. Apart from these exceptions, animals must not be sourced from countries with undetermined BSE risk (Category C), and justifications for the use of animals from countries with undetermined BSE risk (Category C) must always be provided.

3-2-1-2. Sheep and goats (small ruminants)

Naturally occurring clinical scrapie cases have been reported in a number of countries worldwide. As BSE in sheep and goats could possibly be mistaken for scrapie, as a precautionary measure, sourcing of materials derived from small ruminants shall take into account the prevalence of both BSE and scrapie in the country and the tissues from which the materials are derived.

The principles related to "BSE negligible risk (closed) bovine herds" (see section 3-2-2) could equally be applied in the context of small ruminants in order to develop a framework to define the TSE status of a flock of small ruminants.
For sheep, because of the concern over the possibility of BSE in sheep, the use of a genotype(s) showing resistance to BSE/scrapie infection could be considered in establishing TSE free flocks[17]. However, the possibility that genotypes resistant to scrapie could be susceptible to BSE (experimental oral exposure) or atypical scrapie (natural cases) should also be taken into account. Goats have not been studied sufficiently with regard to a genotype specific sensitivity.

Material of small ruminant origin should preferably be sourced from countries with a long history of absence of scrapie. Justification shall be required if the material is sourced from some other origin.

3-2-2 BSE negligible risk (closed) bovine herds

The safest sourcing is from countries or regions with a negligible risk (Category A countries). Other countries may have or have had cases of BSE at some point in time and the practical concept of "Negligible risk (closed) bovine herds" has been developed by the SSC and endorsed by the CHMP and CVMP. Criteria for establishing and maintaining a "BSE negligible risk (closed) bovine herd" can be found in the SSC opinion of 22-23 July 1999[18].

For the time being it is not possible to quantify the reduction of the geographical BSE risk for cattle from BSE 'negligible risk (closed) bovine herds'. However, it is expected that this risk reduction is substantial. Therefore, sourcing from such closed bovine herds shall be considered in the risk assessment in conjunction with the OIE classification of the country.

3-3 ANIMAL PARTS, BODY FLUIDS AND SECRETIONS AS STARTING MATERIAL

In a TSE infected animal, different organs and secretions have different levels of infectivity. If materials from 'TSE-relevant animal species' have to be used, consideration should be given to use materials of the lowest category of risk. The tables given in the Annex of this chapter[19] summarise current data about the distribution of infectivity and PrP^{TSE} in cattle with BSE, and in sheep and goats with scrapie[20].

The information in the tables is based exclusively upon observations of naturally occurring disease or primary experimental infection by the oral route (in cattle) but does not include data on models using strains of TSE that have been adapted to experimental animals, because passaged strain phenotypes can differ significantly and unpredictably from those of naturally occurring disease. Because immunohistochemical and/or Western blot detection of misfolded host protein (PrP^{TSE}) have proven to be a surrogate marker of infectivity, PrP^{TSE} testing results have been presented in parallel with bioassay data. Tissues are grouped into three major infectivity categories, irrespective of the stage of disease:

Category IA	**High-infectivity tissues** **central nervous system (CNS) tissues that attain a high titre of infectivity in the later stages of all TSEs, and certain tissues that are anatomically associated with the CNS**
Category IB	**Lower-infectivity tissues** peripheral tissues that have tested positive for infectivity and/or PrP^{TSE} in at least one form of TSE
Category IC	**Tissues with no detectable infectivity** tissues that have been examined for infectivity, without any infectivity detected, and/or PrP^{TSE}, with negative results

Category IA tissues and substances derived from them shall not be used in the manufacture of medicinal products, unless justified (see Section 5).

Although the category of lower risk tissues (category IB tissues) almost certainly includes some (e.g. blood) with a lower risk than others (e.g. lymphoreticular tissues), the data about infectivity levels in these tissues are too limited to subdivide the category into different levels of risk. It is also evident that the placement of a given tissue in one or another category can be disease and species specific, and subject to revision as new data emerge.

For the risk assessment (see section 4), manufacturers and/or marketing authorisation holders/applicants shall take into account the tissue classification tables in the Annex to this chapter.

The categories in the tables are only indicative and it is important to note the following points.

— In certain situations there could be **cross-contamination** of tissues of different categories of infectivity.
The potential risk will be influenced by the circumstances in which tissues were removed, especially by contact of tissues with lower-infectivity tissues or no detectable infectivity (categories IB and IC tissues) with high-infectivity tissues (category IA tissues). Thus, cross-contamination of some tissues may be increased if infected animals are slaughtered by brain stunning (penetrative or non penetrative) or if the brain and/or spinal cord is sawed. The risk of cross-contamination will be decreased if body fluids are collected with minimal damage to tissue and cellular components are removed, and if foetal blood is collected without contamination

[17] *Opinion of the Scientific Panel on Biological Hazards on 'the breeding programme for TSE resistance in sheep': http://www.efsa.europa.eu/EFSA/efsa_locale-1178620753812_1178620775678.htm*

[19] *The tissue classification tables are based upon the most recent WHO Guidelines on Tissue Infectivity Distribution in Transmissible Spongiform Encephalopathies (2010) http://www.who.int/bloddproducts/tablestissueinfectivity.pdf*

[20] *A Scientific opinion on BSE/TSE infectivity in small ruminant tissues is currently being reviewed by EFSA (Question No EFSA-Q-2010-052). For updated information please follow this link: http://registerofquestions.efsa.europa.eu/roqFrontend/questionsListLoader?mandate=M-2010-0041*

from other maternal or foetal tissues including placenta, amniotic and allantoic fluids. For certain tissues, it is very difficult or impossible to prevent cross-contamination with category IA tissues (e.g. skull). This has to be considered in the risk assessment.

— For certain classes of substances the **stunning/slaughtering techniques** used may be important in determining the potential risk[21] because of the likelihood of disseminating the brain particles into the peripheral organs, particularly to the lungs. Stunning/slaughtering techniques should be described as well as the procedures to remove high infectivity tissues. The procedures to collect the animal tissues/organs to be used and the measures in place to avoid cross-contamination with a higher risk material must also be described in detail.

— The risk of contamination of tissues and organs with BSE-infectivity potentially harboured in central nervous material as a consequence of the stunning method used for cattle slaughtering depends on the following factors:
  — the amount of BSE-infectivity in the brain of the slaughtered animal,
  — the extent of brain damage,
  — the dissemination of brain particles in the animal body.

These factors must be considered in conjunction with the OIE/GBR classification of the source animals, the age of the animals in the case of cattle and the *post-mortem* testing of the cattle using a validated method.

The underlying principles indicated above would be equally applicable to sheep and goats.

The risk posed by cross-contamination will be dependent on several complementary factors including:

— measures adopted to avoid contamination during collection of tissues (see above),
— level of contamination (amount of the contaminating tissue),
— amount and type of materials collected at the same time.

Manufacturers or the marketing authorisation holders/applicants should take into account the risk with respect to cross-contamination.

3-4 AGE OF ANIMALS

As the TSE infectivity accumulates in bovine animals over an incubation period of several years, it is prudent to source from young animals.

Presence of infectious material has essentially been reported in the central nervous system and related tissues, as well as in the lymphoreticular system, depending on the TSE agent (BSE in cattle or scrapie in sheep and goat). The exact time course of infectivity in the respective body parts and tissues, from the date of infection, is not known in both species and, as such, it is difficult to give clear guidance on the age above which the various tissues may be infected and should not be collected. The initial recommendation to collect tissues in the youngest age is still valid. In addition, it is noteworthy that the age criteria depend also on the geographical origin. Age is a more important parameter for materials from countries where the risk is higher (Category B and C countries), than from countries with a negligible BSE risk (Category A countries).

3-5 MANUFACTURING PROCESS

The assessment of the overall TSE risk reduction of a medicinal product shall take into account the control measures instituted with respect to:

— sourcing of the raw/starting materials, and
— the manufacturing process.

Controlled sourcing is a very important criterion in achieving acceptable safety of the product, due to the documented resistance of TSE agents to most inactivation procedures.

A quality assurance system, such as ISO 9000 certification, HACCP[22] or GMP, must be put in place for monitoring the production process and for batch delineation (i.e. definition of batch, separation of batches, cleaning between batches). Procedures shall be put in place to ensure traceability as well as self-auditing and to auditing suppliers of raw/starting materials.

Certain production procedures may contribute considerably to the reduction of the risk of TSE contamination, e.g. procedures used in the manufacture of tallow derivatives (see section 6). As such rigorous processing cannot be applied to many products, processes involving physical removal, such as precipitation and filtration to remove prion-rich material, are likely to be more appropriate than chemical treatments. A description of the manufacturing process, including in-process controls applied, shall be presented and the steps that might contribute to reduction or elimination of TSE contamination should be discussed. Whenever different manufacturing sites are involved, the steps performed at each site shall be clearly identified. The measures in place in order to ensure traceability of every production batch to the source material should be described.

Cleaning process

Cleaning of process equipment may be difficult to validate for the elimination of TSE agents. It is reported that after exposure to high titre preparations of TSE agent, detectable infectivity can remain bound to the surface of stainless steel. The removal of all adsorbed protein by the use of 1 M sodium hydroxide or chlorine releasing disinfectants (e.g. 20 000 ppm chlorine for 1 h) have been considered acceptable approaches where equipment that cannot be replaced has been exposed to potentially contaminated material. Milder treatments with limited concentrations of alkali or stabilized bleach, when properly formulated with detergents and used at specified temperatures, have been shown to exhibit similar efficiency for removing prions as did classical NaOH or chlorine treatments. A system based on vaporised hydrogen peroxide also appeared to be efficient for inactivating TSE agents. These new treatments are more compatible with delicate materials and may be suitable for practical use[23].

If risk materials are used in the manufacture of a product, cleaning procedures, including control measures, shall be put in place in order to minimise the risk of cross-contamination between production batches. This is especially important if materials from different risk categories are handled in the same plant with the same equipment. In the case of using

[21] *SSC opinion on stunning methods and BSE risk (The risk of dissemination of brain particles into the blood and carcass when applying certain stunning methods), adopted at the meeting of 10-11 January 2002. http://ec.europa.eu/food/fs/sc/ssc/out245_en.pdf. Report of the EFSA Working group on BSE risk from dissemination of brain particles in blood and carcass. Question No EFSA-Q-2003-122, adopted on 21 October 2004, http://www.efsa.europa.eu/EFSA/efsa_locale-1178620753812_1178620777397.htm*

[22] *Hazard Analysis Critical Control Point.*

[23] *WHO Guidelines on Tissue Infectivity Distribution in Transmissible Spongiform Encephalopathies (2006) http://www.who.int/bloodproducts/tse/WHO%20TSE%20Guidelines%20FINAL-22%20JuneupdatedNL.pdf*

category IA materials in the manufacture of a product, dedicated equipment shall be used, unless otherwise justified.

Further research is needed to develop and validate new decontamination procedures to lower the risk of cross-contamination for material and devices which are not compatible with WHO-recommended procedures.

Removal/Inactivation validation

Validation studies of removal/inactivation procedures for TSEs can be difficult to interpret. It is necessary to take into consideration the nature of the spiked material and its relevance to the natural situation, the design of the study (including scaling-down of processes) and the method of detection of the agent (*in vitro* or *in vivo* assay). Further research is needed to develop an understanding of the most appropriate "spike preparation" for validation studies. Therefore, validation studies are currently not generally required. However, if claims are made for the safety of the product with respect to TSEs based on the ability of manufacturing processes to remove or inactivate TSE agents, they must be substantiated by appropriate investigational studies[24].

In addition to appropriate sourcing, manufacturers are encouraged to continue their investigations into removal and inactivation methods to identify steps/processes that would have benefit in assuring the removal or inactivation of TSE agents. In any event, a production process wherever possible shall be designed taking account of available information on methods which are thought to inactivate or remove TSE agents.

For certain types of products (see section 6-3 Bovine blood and blood derivatives), where validated removal/inactivation is not readily applicable, process evaluation might be required. This should be based on the starting material and any published data on TSE risk.

4 RISK ASSESSMENT OF MATERIALS OR SUBSTANCES USED IN THE MANUFACTURE AND PREPARATION OF A MEDICINAL PRODUCT IN THE CONTEXT OF REGULATORY COMPLIANCE

The assessment of the risk associated with TSE needs careful consideration of all of the parameters as outlined in section 3-1 (Scientific Principles for Minimising Risk).

As indicated in the introduction to this chapter, regulatory compliance is based on a favourable outcome from a risk assessment. The risk assessments, conducted by the manufacturers and/or the marketing authorisation holders or applicants for the different materials or substances from "TSE-relevant animal species" used in the manufacture of a medicinal product shall show that all TSE risk factors have been taken into account and, where possible, risk has been minimised by application of the principles described in this chapter. TSE Certificates of suitability issued by the EDQM may be used by the marketing authorisation holders or applicants as the basis of the risk assessments.

An overall risk assessment for the medicinal product, conducted by the marketing authorisation holders or applicants, shall take into account the risk assessments for all the different materials from "TSE-relevant animal species" and, where appropriate, TSE reduction or inactivation by the manufacturing steps of the active substance and/or finished product.

The final determination of regulatory compliance rests with the competent authority.

It is incumbent upon the manufacturers and/or the marketing authorisation holders or applicants for both human and veterinary medicinal products to select and justify the control measures for a given "TSE-relevant animal species" derivative, taking into account the latest scientific and technical progress.

5 BENEFIT/RISK EVALUATION

In addition to the parameters as mentioned in sections 3 (that may be covered by a TSE Certificate of Suitability issued by the EDQM) and 4, the acceptability of a particular medicinal product containing materials derived from a "TSE-relevant animal species", or which as a result of manufacture could contain these materials, shall take into account the following factors:

- route of administration of the medicinal product,
- quantity of animal material used in the medicinal product,
- maximum therapeutic dosage (daily dose and duration of treatment),
- intended use of the medicinal product and its clinical benefit,
- presence of a species barrier.

High-infectivity tissues (category IA tissues) and substances derived thereof shall not be used in manufacture of medicinal products, their starting materials and intermediate products (including active substances, excipients and reagents), unless justified. A justification why no other materials can be used shall be provided. In these exceptional and justified circumstances, the use of high-infectivity tissues could be envisaged for the manufacture of active substances, when, after performing the risk assessment as described in Section 4 of this chapter, and taking into account the intended clinical use, a positive benefit/risk assessment can be presented by the marketing authorisation applicant. Substances from category IA materials, if their use is justified, must be produced from animals of countries with negligible BSE risk (Category A).

6 SPECIFIC CONSIDERATIONS

The following materials prepared from "TSE-relevant animal species" are considered in compliance with this chapter provided that they meet at least the conditions specified below. The relevant information or a certificate of suitability granted by the EDQM shall be provided by the marketing authorisation applicant/holder.

6-1 COLLAGEN

Collagen is a fibrous protein component of mammalian connective tissue.

For collagen, documentation to demonstrate compliance with this chapter needs to be provided taking into account the provisions listed in sections 3 to 5. In addition, consideration should be given to the following.

- For collagen produced from bones, the conditions specified for gelatin are applicable (see below). Lower inactivation capacity is expected from the collagen manufacturing process than from that of gelatin. Therefore, sourcing becomes a more critical aspect to consider.
- Collagen produced from tissues such as hides, skins, tendons and sinews do not usually present a measurable TSE risk provided that contamination with potentially infected materials, for example spillage of blood and/or central nervous tissues, is avoided during procurement. Therefore, hides represent a safer raw material for human implants derived from collagen. However, cross-contamination with brain material released during the

[24] *Guideline on the investigation of manufacturing process for plasma-derived medicinal products with regard to vCJD risk CPMP/BWP/5136/03*

slaughtering process that may have dried on the surface of hides would be difficult to eliminate. This is another aspect to consider in the evaluation of safety of this source material.

The collagen manufacturing process can have some steps in common with the manufacture of gelatin such as alkaline and sodium sulphate treatment, calcium hydroxide and sodium hydroxide treatments or enzyme treatment. However, even these common steps can differ in duration and pH condition which can result in significant differences in their inactivation capacity. Manufacturers should at least conduct a process evaluation based on the similarities of the collagen processing steps, as compared to known inactivation steps in the manufacture of gelatin, in order to support the safety of the product. In addition to processing, differences also exist in the final use of the material and, consequently, in their risk assessment, while gelatin is widely used for oral administration, many collagen applications are in the form of surgical implants. This aspect should also be considered in the final risk assessment.

6-2 GELATIN

Gelatin is a natural, soluble protein, gelling or non-gelling, obtained by the partial hydrolysis of collagen produced from bones, hides and skins of animals.

For gelatin, documentation to demonstrate compliance with this chapter needs to be provided taking into account the provisions listed in sections 3 to 5. In addition, consideration should be given to the following[25].

The source material used

Gelatin used in medicinal products can be manufactured from bones or hides.

Hides as the starting material On the basis of current knowledge, hides used for gelatin production represent a safer source material as compared to bones. However, it is highly recommended that measures should be put in place to avoid cross-contamination with potentially infected materials during procurement.

Bones as the starting material Where bones are used to manufacture gelatin, the quality of the starting materials needs to be controlled as an additional parameter to ensure the safety of the final product. Therefore, the following should be applied.

1. Skulls and spinal cord shall be removed from the collected bones (raw/starting material) independent of the age or the country of origin of the cattle.
2. Vertebrae shall be removed from the raw/starting materials from cattle over 30 months from countries with a controlled or an undetermined BSE risk (Categories B or C).
3. Gelatin for parenteral use should only be manufactured from bones coming from countries with a negligible or a controlled BSE risk (Category A and B, respectively). Gelatin for oral use can be manufactured from bones from countries with a negligible, a controlled or an undetermined BSE risk (Category A, B and C, respectively).
4. Gelatin shall be manufactured using one of the manufacturing methods described below.

Manufacturing methods

Hides No specific measures with regard to the processing conditions are required for gelatin produced from hides provided that control measures are put in place to avoid cross-contamination both during the procurement of the hides and during the manufacturing process.

Bones Where bones are used as the starting material, the mode of manufacture will be the second parameter that will ensure the safety of gelatin.

- Gelatin can be manufactured from bones from countries with a negligible, a controlled or an undetermined BSE risk (Categories A, B or C) sourced in accordance with the conditions described in section 6-2 under The source material used, using the acid, alkaline or heat/pressure manufacturing process.
- The manufacturing process shall be taken into consideration when performing the risk assessment as described in Section 4 of this chapter. Both the acid and the alkaline manufacturing methods have shown similar overall inactivation/removal of TSE infectivity in the gelatin validation experiments. Studies have shown that an additional alkaline treatment (pH 13, 2 h) of the bones/ossein further increases the TSE inactivation/removal capacity of the manufacturing process. Other processing steps such as filtration, ion-exchange chromatography and UHT sterilisation also contributes to the safety of gelatin.
- For a typical alkaline manufacturing process, bones are finely crushed, degreased with hot water and demineralised with dilute hydrochloric acid (at a minimum of 4 per cent and pH < 1.5) over a period of at least 2 days to produce the ossein. This is followed by an alkaline treatment with saturated lime solution (pH at least 12.5) for a period of at least 20 days.
- Bovine bones may also be treated by an acid process. The liming step is then replaced by an acid pre-treatment where the ossein is treated at pH < 3.5 for a minimum of 10 hours.
- A "flash" heat treatment (sterilisation) step at 138 °C minimum for 4 s at least is applied to both acid and alkaline manufacturing process.
- In the heat/pressure process, the dried degreased crushed bones are autoclaved with saturated steam at a pressure greater than 3 bar and a minimum temperature of 133 °C, for at least 20 min, followed by extraction of the protein with hot water.

The finishing steps are similar for the alkaline, acid and heat/pressure process and include extraction of the gelatine, washing, filtration and concentration.

6-3 BOVINE BLOOD AND BLOOD DERIVATIVES

Foetal bovine serum is commonly used in cell cultures. Foetal bovine serum should be obtained from foetuses harvested in abattoirs from healthy dams fit for human consumption and the womb should be completely removed and the foetal blood harvested in dedicated space or area by cardiac puncture into a closed collection system using aseptic technique.

Newborn calf serum is obtained from calves under 20 days old and calf serum from animals under the age of 12 months. In the case of donor bovine serum, given that it may be derived from animals less than 36 months old, the TSE negative status of the donor herd shall be well defined and documented. In all cases, serum shall be collected according

[25] *Based on the Opinion of the Scientific Panel on Biological Hazards of the European Food Safety Authority on the 'Quantitative assessment of the human BSE risk posed by gelatine with respect to residual BSE risk'. The EFSA Journal, 312, (1-28). http://www.efsa.europa.eu/EFSA/efsa_locale-1178620753812_1178620776107.htm*
The requirements for source material selection and manufacture are appropriate for oral or parenteral gelatin for use in human and veterinary medicinal products.

to specified protocols by personnel trained in these procedures to avoid cross-contamination with higher risk tissues.

For bovine blood and blood derivatives, documentation to demonstrate compliance with this chapter needs to be provided taking into account the provisions listed in sections 3 to 5. In addition, consideration should be given to the following.

Traceability

Traceability to the slaughterhouse must be assured for each batch of serum or plasma. Slaughterhouses must have available lists of farms from which the animals are originated. If serum is produced from living animals, records must be available for each serum batch which assures the traceability to the farms.

Geographical origin

Whilst tissue infectivity of BSE in cattle is more restricted than scrapie, as a precautionary measure bovine blood should be sourced from Category A countries. Bovine blood from Category B countries is also acceptable provided that there is no risk for cross-contamination of blood with brain material from the slaughter of animals over 21 months[26] of age.

Stunning methods

If it is sampled from slaughtered animals, the method of slaughter is of importance to assure the safety of the material. It has been demonstrated that stunning by captive bolt stunner with or without pithing as well as by pneumatic stunner, especially if it injects air, can destroy the brain and disseminate brain material into the blood stream. Non-penetrative stunning is no more considered as an alternative to penetrative stunning because contamination of blood with brain material has been demonstrated[27]. Negligible risk can be expected from electro-narcosis[28], but this even does not provide strict safety because, when unsuccessful, animals may have to be additionally stunned. The stunning methods must therefore be described for the bovine blood collection process.

Whenever a risk of cross-contamination of blood with brain cannot be avoided at routine slaughtering in countries with a controlled BSE risk (Category B), safety measures such as restriction of the age of the cattle and/or reduction of infectious agents during manufacture have to be applied.

Age

For countries with a controlled BSE risk (Category B), a precautionary age limit of 21 months shall apply for bovine blood or blood derivatives where no significant reduction of TSE agents can be assumed from manufacture. An age limit of 30 months is considered sufficient for blood derivatives where significant reduction of TSE agents can be demonstrated as described below.

Reduction of TSE agents during manufacture

For blood derivatives, the capacity of the manufacturing process to reduce/eliminate TSE agents should be estimated from investigational studies. The estimation may be based on published data or in house data whenever it can be shown that such data is relevant to the specific manufacturing process. If it cannot be concluded that the reduction capacity is comparable, it is recommended that manufacturers undertake product-specific investigational studies. Investigations using biochemical assay may be sufficient if there is scientific evidence that this assay correlates with infectivity data. General guidance for investigational studies on reduction of TSE agents has been outlined[29]. Brain-derived spike preparations are appropriate for studies investigating the risk from brain-contaminated blood.

6-4 TALLOW DERIVATIVES

Tallow is fat obtained from tissues including subcutaneous, abdominal and inter-muscular areas and bones. Tallow used as the starting material for the manufacture of tallow derivatives shall be 'Category 3 material or equivalent', as defined in Regulation (EC) No 1774/2002 of the European Parliament and of the Council of 3 October 2002 laying down health rules concerning animal by-products not intended for human consumption.

Tallow derivatives, such as glycerol and fatty acids, manufactured from tallow by rigorous processes are thought unlikely to be infectious and they have been the subject of specific consideration by CHMP and CVMP. For this reason, such materials manufactured under the conditions at least as rigorous as those given below shall be considered in compliance for this chapter, irrespective of the geographical origin and the nature of the tissues from which tallow derivatives are derived. Examples of rigorous processes are:

- trans-esterification or hydrolysis at not less than 200 °C for not less than 20 min under pressure (glycerol, fatty acids and fatty acid esters production),
- saponification with 12 M NaOH (glycerol and soap production):
  - batch process: at not less than 95 °C for not less than 3 h,
  - continuous process: at not less than 140 °C, under pressure for not less than 8 min, or equivalent,
- distillation at 200 °C.

Tallow derivatives manufactured according to these conditions are unlikely to present any TSE risk and shall therefore be considered compliant with this chapter.

Tallow derivatives produced using other conditions must demonstrate compliance with this chapter.

6-5 ANIMAL CHARCOAL

Animal charcoal is prepared by carbonisation of animal tissues, such as bones, using temperatures higher than 800 °C. Unless otherwise justified, the starting material for the manufacture of animal charcoal shall be Category 3 material or equivalent, as defined in Regulation (EC) No 1774/2002 of the European Parliament and of the Council of 3 October 2002 laying down health rules concerning animal by-products not intended for human consumption. Irrespective of the geographical origin and the nature of the tissue, for the purpose of regulatory compliance, animal charcoal shall be considered in compliance with this chapter.

Charcoal manufactured according to these conditions is unlikely to present any TSE risk and shall therefore be considered compliant with this chapter. Charcoal produced using other conditions must demonstrate compliance with this chapter.

Table 5.2.8.-1. – *Concept for acceptance of bovine blood/sera and derivatives*

Product	Foetal bovine serum	Donor calf serum	Adult bovine donor serum	Calf serum	Adult bovine serum / plasma	Adult bovine serum / plasma / serum derivative	Adult bovine serum derivative	Adult bovine serum derivative
Geographical origin of cattle	Cat. A and B	Cat. A and B	Cat. A and B[1]	Cat. A and B	Cat. A	Cat. B	Cat. A	Cat. B
Age of cattle	unborn	< 1 year	< 36 months	< 1 year	No limit	< 21 months[2]	No limit	< 30 months
Slaughtering/cross-contamination of blood with CNS material	No risk of cross-contamination			Risk of cross-contamination				
Demonstration of Prion reduction during manufacture	No			No				Yes[3]

1. When sourced in Category B countries, cattle should be from well-defined and documented herds.
2. A higher age may be allowed if cross-contamination of blood with CNS material can be clearly ruled out (e.g. halal slaughter).
3. Demonstration of prion reduction may not be required if cross-contamination of blood with CNS material can be clearly ruled out (e.g. halal slaughter).

6-6 MILK AND MILK DERIVATIVES

In the light of the current scientific knowledge and irrespective of the geographical origin, bovine milk is unlikely to present any risk of TSE contamination[30].

Certain materials, including lactose, are extracted from whey, the spent liquid from cheese production following coagulation. Coagulation can involve the use of calf rennet, an extract from abomasum, or rennet derived from other ruminants. The CHMP/CVMP have performed a risk assessment for lactose and other whey derivatives produced using calf rennet and concluded that the TSE risk is negligible if the calf rennet is produced in accordance with the process described in the risk assessment report[31].
The conclusion was endorsed by the SSC[32] which has also performed an assessment of the TSE risk of rennet in general[33].

Bovine milk derivatives manufactured according to the conditions described below are unlikely to present any TSE risk and shall therefore be considered compliant with this chapter.

— The milk is sourced from healthy animals in the same conditions as milk collected for human consumption, and
— no other ruminant materials, with the exception of calf rennet, are used in the preparation of such derivatives (e.g. pancreatic enzyme digests of casein).

Milk derivatives produced using other processes or rennet derived from other ruminant species must demonstrate compliance with this chapter.

6-7 WOOL DERIVATIVES

Derivatives of wool and hair of ruminants, such as lanolin and wool alcohols derived from hair shall be considered in compliance with this chapter, provided the wool and hair are sourced from live animals.

Wool derivatives produced from wool which is sourced from slaughtered animals declared "fit for human consumption" and the manufacturing process in relation to pH, temperature and duration of treatment meets at least one of the stipulated processing conditions listed below are unlikely to present any TSE risk and shall therefore be considered compliant with this chapter.

— Treatment at pH $\geq$ 13 (initial; corresponding to a NaOH concentration of at least 0.1 M NaOH) at 60 °C for at least 1 h. This occurs normally during the reflux stage of the organic-alkaline treatment.
— Molecular distillation at $\geq$ 220 °C under reduced pressure.

Wool derivatives produced using other conditions must demonstrate compliance with this chapter.

6-8 AMINO ACIDS

Amino acids can be obtained by hydrolysis of materials from various sources.

Unless otherwise justified, the starting material for the manufacture of amino acids shall be 'Category 3 material or equivalent', as defined in Regulation (EC) No 1774/2002 of the European Parliament and of the Council of 3 October 2002 laying down health rules concerning animal by-products not intended for human consumption.

Amino acids prepared using the following processing conditions are unlikely to present any TSE risk and shall be considered compliant with this chapter:

— amino acids produced from hides and skins by a process which involves exposure of the material to a pH of 1 to 2, followed by a pH of > 11, followed by heat treatment at 140 °C for 30 min at 3 bar,
— the resulting amino acids or peptides must be filtered after production, and
— analysis is performed using a validated and sensitive method to control any residual intact macromolecules, with an appropriate limit set.

Amino acids prepared using other conditions must demonstrate compliance with this chapter.

6-9 PEPTONES

Peptones are partial hydrolysates of protein, achieved by enzymic or acid digestion. They are used in microbiological culture media to support the nutritional requirements of micro-organisms, which might be used as seed stocks or in industrial scale fermentations for the production of human and veterinary medicinal products, including vaccines. There

[30] *For milk and milk derivatives from small ruminants, please see EFSA opinion on Question No EFSA-Q-2008-310, adopted on 22 October 2008, http://www.efsa.europa.eu/en/scdocs/scdoc/849.htm*

[31] *Committee for Medicinal Products for Human Use and its Biologics Working Party conducted a risk and regulatory assessment of lactose prepared using calf rennet. The risk assessment included the source of the animals, the excision of the abomasums and the availability of well-defined quality assurance procedures. The quality of any milk replacers used as feed for the animals from which abomasums are obtained is particularly important. The report can be found on http://www.ema.europa.eu/pdfs/human/press/pus/057102.pdf*

[32] *Provisional statement on the safety of calf-derived rennet for the manufacture of lactose, adopted by the SSC at its meeting of 4-5 April 2002 (http://ec.europa.eu/food/fs/sc/ssc/out255_en.pdf)*

[33] *The SSC issued an opinion on the safety of animal rennet in regard to risks from animal TSE and BSE in particular, adopted at its meeting of 16 May 2002 (http://ec.europa.eu/food/fs/sc/ssc/out265_en.pdf)*

is considerable interest in the use of vegetable protein as an alternative to animal sourced protein. However:

— where gelatin is used as the protein source material, reference is made to section 6-2 Gelatin, of this chapter,
— where casein is used as the protein source material, reference is made to section 6-6 Milk and milk derivatives, of this chapter,
— where tissue of TSE-relevant animal species is the protein source material, the tissue must be sourced from animals fit for consumption (see section 3-2 Source animals, of this chapter) with a maximum age of 30 months old for cattle from countries with a controlled BSE risk (Category B). The age of animals is of minimal concern for animals from countries with a negligible BSE risk (Category A).

ANNEX: MAJOR CATEGORIES OF INFECTIVITY

The tables below are taken from the *WHO Guidelines on Tissue Infectivity Distribution in Transmissible Spongiform Encephalopathies (2010)*.

Data entries are shown as follows:

+	=	Presence of infectivity or PrP^{TSE}
–	=	Absence of detectable infectivity or PrP^{TSE}
NT	=	Not tested
NA	=	Not applicable
?	=	Uncertain interpretation
0	=	Limited or preliminary data
[]	=	Infectivity or PrP^{TSE} data based exclusively on bioassays in transgenic (Tg) mice over-expressing the PrP-encoding gene or PRP^{TSE} amplification methods

1. Infectivity bioassays of human tissues have been conducted in either primates or mice (or both), bioassays of cattle tissues have been conducted in either cattle or mice (or both), and most bioassays of sheep and/or goat tissues have been conducted only in mice. In regard to sheep and goats not all results are consistent for both species, for example, two goats (but no sheep) have contracted BSE naturally [Eurosurveillance, 2005, Jeffrey et al., 2006]. Similarly, most of the results described for CWD were derived from studies in deer, and findings may not be identical in elk or other cervids.

2. In experimental models of TSE, the optic nerve has been shown to be a route of neuroinvasion, and contains high titres of infectivity.

3. No experimental data about infectivity in pituitary gland or dura mater in humans with all forms of human TSE have been reported, but cadaveric dura mater patches, and growth hormone derived from cadaveric pituitaries have transmitted disease to hundreds of people and therefore must be included in the category of high-risk tissues. PrP^{TSE} was detected by immunoblot in the dura mater of a vCJD patient who died in the US after an unusually long incubation period (see also Table IB for other positive tissues: skin, kidney, liver, pancreas, ovary and uterus) [Notari et al., 2010]. It must be mentioned that earlier studies of numerous cases examined in the UK reported all of these tissues to be negative [Ironside et al., 2002, Head et al., 2004].

4. In cattle, PrP^{TSE} is reported to be inconsistently present in the enteric plexus in the distal ileum, but immunohistochemical examination of tissues from a single 'fallen stock' case of BSE in Japan suggested (albeit equivocally) involvement of myenteric plexuses throughout the small and large intestine [Kimura and Haritani, 2008].

5. In vCJD, PrP^{TSE} is limited to gut-associated lymphoid and nervous tissue (mucosa, muscle, and serosa are negative).

6. Ruminant fore stomachs (reticulum, rumen, and omasum) are widely consumed, as is the true stomach (abomasum). The abomasum of cattle (and sometimes sheep) is also a source of rennet.

7. When a large BSE oral dose was used to infect cattle experimentally, infectivity was detected in the jejunum and the ileo-caecum junction in Tg mice overexpressing PrP [courtesy of Dr M Groschup]. PrP^{TSE} was detected at low incidence in lymphoid tissue of ileum [Terry et al., 2003] and has been detected at an even lower frequency in jejunal lymphoid tissue of cattle similarly infected by the oral route [EFSA, 2009].

8. A single report of transmission of sporadic CJD infectivity from human placenta has never been confirmed and is considered improbable.

9. PrP^{TSE} has been detected in scrapie-infected sheep with chronic mastitis, but not from infected sheep without mastitis [Ligios et al., 2005].

10. Studies in hamsters orally infected with scrapie revealed that PrP^{TSE} deposition in skin was primarily located within small nerve fibres. Also, apical skin 'velvet' from the antlers of CWD-infected deer is reported to contain PrP^{TSE} and infectivity [Angers et al., 2009].

11. PrP^{TSE} detected by immunocytochemistry in the renal pelvis of scrapie-infected sheep [Siso et al., 2006], and in lymphoid follicles within connective tissue adjacent to the renal pelvis in CWD-infected mule deer [Fox et al., 2006].

12. A single positive marrow in multiple transmission attempts from cattle orally dosed with BSE-infected brain [Wells et al., 1999, Wells et al., 2005, Sohn et al., 2009].

13. Muscle homogenates have not transmitted disease to primates from humans with sporadic CJD, or to cattle from cattle with BSE. However, intra-cerebral inoculation of a semitendinosus muscle homogenate (including nervous and lymphatic elements) from a single cow with clinical BSE has transmitted disease to transgenic mice that overexpress PrP at a rate indicative of trace levels of infectivity [Buschmann and Groschup, 2005]. Also, recent published and unpublished studies have reported the presence of PrP^{TSE} in skeletal muscle in experimental rodent models of scrapie and vCJD [Beekes et al., 2005], in experimental and natural scrapie infections of sheep and goats [Andreoletti et al., 2004], in sheep orally dosed with BSE [Andreoletti, unpublished data], and in humans with sporadic, iatrogenic, and variant forms of CJD [Glatzel et al., 2003, Kovacs et al., 2004, Peden et al., 2006]. Bioassays of muscle in transgenic mice expressing cervid PrP have documented infectivity in CWD-infected mule deer [Angers et al., 2006], and experiments are underway to determine whether detectable PrP^{TSE} in other forms of TSE is also associated with infectivity.

14. In cattle, bioassay of infectivity in the tongue was negative, but the presence of infectivity in palatine tonsil has raised concern about possible infectivity in lingual tonsillar tissue at the base of the tongue that may not be removed at slaughter [Wells et al., 2005, EFSA, 2008]. In sheep naturally infected with scrapie, 7 of 10 animals had detectable PrP^{TSE} in the tongue [Casalone et al., 2005, Corona et al., 2006].

15. Limited chiefly to regions involved in olfactory sensory reception.

16. Because only one case of iatrogenic CJD has been certainly attributed to a corneal transplant among hundreds of thousands of recipients (one additional case is considered probable, and another case only possible), cornea has been categorized as a lower-risk tissue, other anterior chamber tissues (lens, aqueous humour, iris, conjunctiva) have been tested with a negative result both in vCJD and other human TSEs, and there is no epidemiological evidence that they have been associated with iatrogenic disease transmission.

17. A wealth of data from studies of blood infectivity in experimental rodent models of TSE have been extended by recent studies documenting infectivity in the blood of sheep with naturally occurring scrapie and in sheep transfused with blood from BSE-infected cattle [Houston et al., 2008], of deer with naturally occurring CWD [Mathiason et al., 2006], and (from epidemiological observations) in the red cell fraction (which includes significant amounts of both plasma and leukocytes) of four blood donors in the pre-clinical phase of vCJD infections [reviewed in Brown, 2006, Hewitt et al., 2006]. Plasma Factor VIII administration has also been potentially implicated in a subclinical case of vCJD in a haemophilia patient [Peden et al., 2010]. Blood has not been shown to transmit disease from humans with any form of 'classical' TSE [Dorsey et al., 2009], or from cattle with BSE (including fetal calf blood). A number of laboratories using new, highly sensitive methods to detect PrP^{TSE} are reporting success in a variety of animal and human TSEs. However, several have experienced difficulty obtaining reproducible results in plasma, and it is not yet clear that positive results imply a potential for disease transmissibility, either because of false positives, or of 'true' positives that are due to sub-transmissible concentrations of PrP^{TSE}. Because of these considerations (and the fact that no data are yet available on blinded testing of specimens from naturally infected humans or animals) the expert group felt that it was still too early to evaluate the validity of these tests with sufficient confidence to permit either a negative or positive conclusion.

18. Evidence that infectivity is not present in milk from BSE-infected bovines includes temporo-spatial epidemiologic observations failing to detect maternal transmission to calves suckled for long periods, clinical observations of over a hundred calves suckled by infected cows that have not developed BSE, and experimental observations that milk from infected cows reared to an age exceeding the minimum incubation period has not transmitted disease when administered intra-cerebrally or orally to mice [Middleton and Barlow, 1993, Taylor et al., 1995]. Also, PrP^{TSE} has not been detected in milk from cattle incubating BSE following experimental oral challenge [SEAC, 2005]. However, low levels (µg to ng/L) of normal PrP have been detected in milk from both animals and humans [Franscini et al., 2006]. PrP^{TSE} has been detected in the mammary glands of scrapie-infected sheep with chronic mastitis [Ligios et al., 2005], and very recently it has been reported that milk (which in some cases also contained colostrum) from scrapie-infected sheep transmitted disease to healthy animals [Konold et al., 2008, Lacroux et al., 2008].

19. A mixed inoculum of urine and faeces from naturally infected CWD deer did not transmit disease during an 18-month observation period after inoculation of healthy deer with a heterozygous (96 G/S) PRNP genotype [Mathiason et al., 2006]. However, recent bioassays in Tg mice have transmitted disease from both urine [Haley et al., 2009] and faeces [Tamgüney et al., 2009]. In addition, mice with lymphocytic nephritis that were experimentally infected with scrapie shed both PrP^{TSE} and infectivity in urine, when bioassayed in Tg mice [Seegeret al., 2005]. Very low levels of infectivity have also been detected in the urine (and histologically normal kidneys) of hamsters experimentally infected with scrapie [Gregori and Rohwer, 2007, Gonzalez-Romero et al., 2008]. Finally, in an experimental scrapie-hamster model, oral dosing resulted in infectious faeces when bioassayed in Tg mice over-expressing PrP [Safar et al., 2008].

20. Embryos from BSE-affected cattle have not transmitted disease to mice, but no infectivity measurements have been made on fetal calf tissues other than blood (negative mouse bioassay) [Fraser and Foster, 1994]. Calves born of dams that received embryos from BSE- affected cattle have survived for observations periods of up to seven years, and examination of the brains of both the unaffected dams and their offspring revealed no spongiform encephalopathy or PrP^{TSE} [Wrathall et al., 2002].

21. Early reports of transmission of sporadic CJD infectivity from human cord blood and colostrum have never been confirmed and are considered improbable. A bioassay from a cow with BSE in transgenic mice over-expressing bovine PrP gave a negative result [Buschmann and Groschup, 2005], and PrP^{TSE} has not been detected in colostrum from cattle incubating BSE following experimental oral challenge [SEAC, 2005].

Appendix XXIII

BRP	Biological reference preparation (see Appendix I E).
BS	British Standard.
$CCID_{50}$	Cell culture infective dose (the dose of the micro-organism that infects 50% of the cell cultures inoculated).
CIP*	Collection de Bactéries de l'Institut Pasteur.
CRS	Chemical reference substance (see Appendix I E).
DNA	Deoxyribonucleic acid.
EID_{50}	Egg embryos infective dose (the dose of the micro-organism that infects 50% of the embryonated eggs inoculated).
EPBRP	European Pharmacopoeia Biological Reference Preparation (see Appendix I E).
EPCRS	European Pharmacopoeia Chemical Reference Substance (see Appendix I E).
FIP	International Pharmaceutical Federation.
g	Acceleration due to gravity.
HIV	Human immunodeficiency virus
ID_{50}	Infective dose 50 (the dose of the micro-organism that infects 50% of the animals inoculated).
IMI*	Commonwealth Mycological Institute.
IP*	Collection Nationale de Cultures de Microorganismes (CNCM).
ISO	International Organization for Standardization.
IU	International Unit
IUPAC	International Union of Pure and Applied Chemistry.
LD_{50}	Lethal dose 50 (the dose of the preparation or organism that kills 50% of the animals inoculated).
MID	Minimum infective dose.
MLD	Minimum lethal dose.
MRI	Magnetic resonance imaging.
NCIMB*	National Collection of Industrial and Marine Bacteria.
NCPF*	National Collection of Pathogenic Fungi.
NCTC*	National Collection of Type Cultures.
NCYC*	National Collection of Yeast Cultures.
PD_{50}	Protective dose 50 (the dose of the preparation that protects 50% of the animals inoculated).
ppm	Parts per million by weight.
SI	International System of Units.
SN_{50}	Serum neutralising dose 50 (the amount of serum that will protect 50% of the cultures against the specified amount of virus).
SSI	Statens Serum Institut (Copenhagen).
THM	Traditional Herbal Medicine.
THMP	Traditional Herbal Medicinal Product.
VS	Volumetric solution (see Appendix I B).
µkat	Microkatal: the enzyme activity that, under defined conditions, produces 1 micromole of the reaction product per second or consumes one micromole of the reaction substrate per second.

*Strains of the micro-organisms referred to in the Pharmacopoeia may be obtained from:

Appendix XXV

Names, Symbols and Atomic Weights of Elements

The following atomic weights are those published in 2001 by the International Union of Pure and Applied Chemistry (*Pure Appl. Chem.* 2003, 75, 1107).

Element	Symbol	Atomic Weight	Element	Symbol	Atomic Weight
Actinium	Ac	[227]	Molybdenum	Mo	95.94
Aluminium	Al	26.981538	Neodymium	Nd	144.24
Americium	Am	[243]	Neon	Ne	20.1797
Antimony	Sb	121.760	Neptunium	Np	[237]
Argon	Ar	39.948	Nickel	Ni	58.6934
Arsenic	As	74.92160	Niobium	Nb	92.90638
Astatine	At	[210]	Nitrogen	N	14.0067
Barium	Ba	137.327	Nobelium	No	[259]
Berkelium	Bk	[247]	Osmium	Os	190.23
Beryllium	Be	9.012182	Oxygen	O	15.9994
Bismuth	Bi	208.98038	Palladium	Pd	106.42
Bohrium	Bh	[264]	Phosphorus	P	30.973761
Boron	B	10.811	Platinum	Pt	195.078
Bromine	Br	79.904	Plutonium	Pu	[244]
Cadmium	Cd	112.411	Polonium	Po	[209]
Caesium	Cs	132.90545	Potassium	K	39.0983
Calcium	Ca	40.078	Praseodymium	Pr	140.90765
Californium	Cf	[251]	Promethium	Pm	[145]
Carbon	C	12.0107	Protactinium	Pa	231.03588
Cerium	Ce	140.116	Radium	Ra	[226]
Chlorine	Cl	35.453	Radon	Rn	[222]
Chromium	Cr	51.9961	Rhenium	Re	186.207
Cobalt	Co	58.933200	Rhodium	Rh	102.90550

Supplementary Chapters

Introduction

Supplementary Chapters contain no standards, tests or assays nor any other mandatory specifications with respect to any Pharmacopoeial article. They comprise explanatory and other ancillary texts and are provided for the assistance and information of users of the Pharmacopoeia.

Contents of the Supplementary Chapters

SUPPLEMENTARY CHAPTER I A731
Basis of Pharmacopoeial Requirements A731
A. Control of Impurities A732
B. Polymorphism A735
C. Bacterial Endotoxin Testing A736
D. Excipients A741
E. Dissolution Testing of Solid Oral Dosage Forms A741
F. Declaration of Content A744
G. Labelling A744
H. Biological Assays and Tests A745
J. Efficacy of Antimicrobial Preservation A746
K. Stereochemistry A747
L. Microbiological Assay of Antibiotics A747
M. Microbial Contamination A750
N. Particulate Contamination A751
O. Inhaled Products A753

SUPPLEMENTARY CHAPTER II A754
Names of Medicinal Substances and Preparations A754
A. Changes in Monograph Titles A754
B. Monograph Titles for Formulated Preparations A754
C. Structures and Nomenclature of Substances of Natural or Semi-synthetic Origin A756

SUPPLEMENTARY CHAPTER III A762
Pharmacopoeial Organisation A762
A1. Contact Points A762
A2. Expert Advisory Groups A762
B. Monograph Development: Mechanism A763
C. Monograph Development: Guidance to Manufacturers A763
D. Monograph Development: Methods of Analysis A766

I. Chromatograms for Information *(Transferred to BP website* www.pharmacopoeia.com)

J. Control of Impurities in Substances for Pharmaceutical Use A820
K. Characters Section in Monographs A824
L. Alternative Methods for Control of Microbiological Quality A824
M. Reference Standards A834
N. Gene Transfer Medicinal Products for Human Use A838
O. Functionality-related Characteristics of Excipients A851
P. Guidelines for Using the Test for Sterility A853
Q. Elemental Impurities A854
R. Chemometric Methods Applied to Analytical Data A854
S. Raw Materials of Biological Origin for the Production of Cell-based and Gene Therapy Medicinal Products A873
T. Depyrogenation of Items used in the Production of Parenteral Preparations A877
U. Multivariate Statistical Process Control A878

SUPPLEMENTARY CHAPTER V A884
Unlicensed Medicines A884
A. Monograph Selection: Unlicensed Medicines A886
B. Preservative-free Unlicensed Medicines A886
C. Bioequivalence of Oral Liquids A887
D. Storage and Stability of Unlicensed Medicines A887
E. Extemporaneous Preparations A888
F. Aseptic Preparations of Unlicensed Medicines A888

SUPPLEMENTARY CHAPTER VI A896
Pharmacopoeial Quantitative Analysis A896
A. Pharmacopoeial Calculations A896
B. Titrimetric Analysis A898
C. Indicator Colour Changes A899

SUPPLEMENTARY CHAPTER VII A903
A. Traditional Herbal Medicines A903
B. Names of Herbal Drugs Used in Traditional Chinese Medicine A903
C. Monographs on Herbal Drug Extracts A905
D. DNA Barcoding as a Tool for Identification of Herbal Drugs A907
E. Methods of Pretreatment for Preparing Traditional Chinese Drugs: General Information A911

SUPPLEMENTARY CHAPTER VIII A914
Materials for use in the Manufacture of Homoeopathic Preparations A914

SUPPLEMENTARY CHAPTER IX A915
Similar Biological Medicinal Products A915

SUPPLEMENTARY CHAPTER X A917
Supplementary Chapter on the use of Analytical Quality by Design concepts for analytical procedures A917

Supplementary Chapter I

Basis of Pharmacopoeial Requirements

Introduction

This chapter provides explanatory text and guidance on the pharmacopoeial approach to a range of subjects.

Separate, lettered sections of this chapter explain the current approach to a particular aspect of pharmacopoeial control and, where appropriate, give an indication of future developments. The British Pharmacopoeia Commission's policies continue to evolve and these sections will be updated as and when necessary to reflect further developments.

While these texts outline general policies that are adopted in the Pharmacopoeia, each monograph is considered individually. Departures from the general rule are accepted where justified and are accommodated by appropriate statements in the individual monographs.

In providing these texts to users of the Pharmacopoeia it is emphasised that the specifications of the Pharmacopoeia are one facet of the overall control of the quality of medicinal products and their constituents. Those concerned with the manufacture of medicinal substances and those responsible for their incorporation into pharmaceutical dosage forms must also pay due attention to the requirements and recommendations of other competent authorities. Within the European Community the information required for marketing authorization is laid down in the relevant Directives, Notice to Applicants and associated Notes for Guidance available from the Commission of the European Communities as the series 'The Rules Governing Medicinal Products in the European Community'.

Dialogue with users is an essential element of pharmacopoeial development and the British Pharmacopoeia Commission hopes that this chapter will provide insight into certain features of pharmacopoeial requirements.
The Commission places great value on the assistance it receives from manufacturers and others with the necessary knowledge to assist it in its work. It welcomes suggestions for improvement of published texts and constructive comment on any issues of interest and concern to users.

General considerations

1. A proper understanding of the basis on which the requirements of the Pharmacopoeia are established is essential to the correct interpretation of the requirements.

2. The Pharmacopoeia contributes significantly to the overall control of the quality of medicinal products and provides a publicly available statement concerning the quality that a product or a component of a product is expected to meet at any time during its period of use. Pharmacopoeial specifications are used within licensing systems and by manufacturers, suppliers, purchasers and those acting on behalf of consumers of medicinal products.

3. A manufacturer must recognise that a product or material may be challenged at any time during its claimed period of use by the methods of the Pharmacopoeia and that it must then comply with the pharmacopoeial requirements. These requirements allow for acceptable levels of change that may occur during storage and distribution and reject articles showing unacceptable levels of change. Frequently a manufacturer will need to apply more stringent test limits at the time of release of a batch of the product or material in order to ensure compliance. As stated in the General Notices, a manufacturer may assure himself that the requirements of the Pharmacopoeia will be met by means other than routinely performing all of the tests prescribed in the Pharmacopoeia. It is emphasised that the circumstances under which, and the frequency with which, tests of the Pharmacopoeia should be performed by a manufacturer as part of his overall quality assurance are ultimately matters for agreement between the manufacturer and the competent authority.

4. The requirements included in a monograph, other than any instructions given under the side-heading Production, are designed to provide the means by which an independent judgement can be made as to the overall quality of a particular article. A manufacturer in possession of detailed knowledge of the manufacturing process may have no need to carry out certain tests. The example of some impurity tests in monographs for formulated preparations is discussed in more detail in section A of this chapter. The methods described in the Pharmacopoeia must be robust because they are intended to be used by analysts in a wide range of laboratories, sometimes on an infrequent basis.
Understandably, a manufacturer may wish to use other methods that may be more suitable for frequent use or automation and is entitled to do so. However in the event of any doubt or dispute as to whether or not a material is of pharmacopoeial quality, as the General Notice on Assays and Tests makes clear, the methods of the Pharmacopoeia alone are authoritative.

5. This view of pharmacopoeial requirements is also significant when considering the size of sample to be taken for test. In an overall programme designed to give assurance of quality of a manufactured product, the statistical validity of any sampling programme must be beyond doubt.
The standards of the Pharmacopoeia, on the other hand, are intended to apply to the sample available, perhaps the container of dispensed tablets provided to a patient in accordance with a prescription. The Pharmacopoeia requires that twenty of those tablets should meet the test for Uniformity of weight. A manufacturer establishing a sampling and testing protocol designed to ensure ultimate compliance with the pharmacopoeial requirements will need to operate at a level designed to show with an acceptable degree of confidence that any twenty tablets, taken at random from a given batch, will meet the requirements.

6. Pharmacopoeial methods and limits are set with the intention that they should be used as compliance requirements and not as requirements to guarantee total quality assurance. An article is not of pharmacopoeial quality if any sample of the size stipulated in the monograph taken at any time during storage, distribution and use within the accepted shelf-life fails to meet all of the requirements.

7. Arising from this it may be useful to underline that compliance of a product with pharmacopoeial requirements demands that the product meets *all* mandatory aspects of the appropriate monograph and that those requirements shall be interpreted in the light of any relevant General Notices.
In certain cases individual requirements of particular tests may seem to be incompatible with those of other tests; where this is apparently the case such requirements have been framed intentionally. For example, the requirement for the overall content of active ingredient in a tablet preparation, as determined on a powdered sample of twenty tablets, might be 95.0 to 105.0% of the stated amount. Thus an assay result of 96.0% would indicate compliance. For the Uniformity of content test a further ten tablets might be

individually examined, each tablet being required to contain between 85 and 115% of the mean value, with the possibility of a single exception between 75 and 125%. Thus if nine out of ten tablets fall within the range (assuming the mean to be 96.0%) 81.6 and 110.4% and the tenth falls within the range 72.0 to 120.0% then the tablets examined comply with that requirement. For the Dissolution test each tablet examined might be required to yield at least 70% of the labelled claim into solution within 45 minutes. It has been suggested that since a single outlier tablet might contain as little as 72.0% of the labelled claim and yet still fall within the acceptance limits for content, the requirements for dissolution should be relaxed to take this into account. In framing requirements, however, the view is taken that it is neither realistic nor profitable to attempt to compound the results of various tests in this way. Each test in a pharmacopoeial monograph and the acceptance limit is therefore framed as an individual entity with requirements based on values encountered in practice; compliance with the monograph requires compliance with each and every test.

8. The philosophy outlined above has an important bearing on the construction of a monograph for the Pharmacopoeia. To achieve maximum benefit from the examination of a product the recommended approach is that, wherever possible, a variety of different analytical techniques should be employed. The monographs of the British Pharmacopoeia are, therefore, usually constructed to use fundamentally different procedures for assay and for the examination for impurities. For a medicinal substance the general approach has been to employ spectrophotometric or other appropriate techniques for identification, chromatographic techniques for the control of impurities and a precise, albeit non-specific method for assay. It has been held that this approach confers greater confidence in the verification of the identity and quality of the substance and in the detection of unexpected impurities than would be the case in using, for example, a single stability-indicating liquid chromatographic method for all three purposes. The British Pharmacopoeia Commission recognises, however, that as chromatographic methods become more precise it will become increasingly possible to use them for assay purposes thereby combining precision with specificity and economising upon analytical effort and time. For dosage forms this concept has already been adopted and more specific assay methods, such as those employing liquid chromatography, are being employed increasingly.

9. A discussion of the basis of pharmacopoeial requirements would be incomplete without reminding users that any article described by a name at the head of a monograph in the current edition of the Pharmacopoeia, *whether or not it is referred to as 'BP'*, must comply with that monograph. The name at the head of a monograph is to be interpreted in accordance with the General Notice on Titles. In particular, a formulated preparation that is labelled with a title that includes the full nonproprietary name of the active ingredient, where this is not included in the title of the monograph, must also comply with the monograph. Thus, for example, a preparation labelled Labetalol Hydrochloride Tablets must comply with the monograph for Labetalol Tablets.

A. Control of Impurities

This section provides a guide to the pharmacopoeial approach to the control of impurities in medicinal substances and formulated preparations. Other guidance relevant to manufacturers is provided in, for example, ICH guidelines on impurities in new drug substances (Q3A) and new drug preparations (Q3B) and VICH guidelines on impurities in new veterinary drug substances (GL10) and new veterinary medicinal products (GL11).

1. This section relates primarily to totally synthetic organic medicinal substances and those substances obtained by synthetic modification of a naturally-produced precursor. It is not necessarily applicable to other organic substances (e.g., those of plant or animal origin), inorganic substances and excipients.

Certain additional information of specific relevance to impurity control in the formulated preparation monographs of the British Pharmacopoeia is also provided.

2. The control provided by chemical tests limiting the levels of particular impurities or classes of impurities is often augmented by physical tests such as absorbance, specific optical rotation, melting point and clarity and colour of solution and, for a liquid, refractive index, boiling point range and weight per mL.

3. Tests such as sulfated ash and loss on drying are non-specific but they contribute to an assurance of the general quality of the material, the use of good pharmaceutical manufacturing practice in its production, the avoidance of contamination especially by inorganic substances and the removal of volatile solvents. Typical limits are 0.1% for sulfated ash and 0.5% for loss on drying.

4. Tests for purity are intended to provide appropriate limitation of known potential or actual impurities rather than to provide against all possible impurities. The tests are not necessarily designed to detect any adventitious contaminants or adulteration. Material found to contain an impurity not detectable by means of the prescribed tests is not of pharmacopoeial quality if the nature or amount of the impurity found is incompatible with good pharmaceutical practice.

5. Some medicinal substances are mixtures of closely related compounds. Where these components have similar activity they are not usually regarded as impurities and may indeed contribute to the result obtained in the assay. Examples include Erythromycin, Gentamicin Sulfate and Sodium Lauryl Sulfate. It may however be appropriate to control the relative amounts of such components, e.g., gentamicins C_1, C_{1a}, C_2, C_{2a} and C_{2b} in Gentamicin Sulfate in order to ensure batch to batch consistency for material from one manufacturer and uniformity between supplies of the same substance from different manufacturers.

6. Many medicinal substances already on the market have been made available as racemic mixtures with little or nothing known about the biological activities of the separate isomers. This has been reflected in the monograph in the Pharmacopoeia and a test to show that the substance is the racemic mixture has not usually been included unless it was known that at least one of the separate enantiomers was also available commercially. Nevertheless, with increasing concern by regulatory authorities for substances to be made available as single isomers, tests for enantiomeric composition will become more common. When a medicinal substance is a racemate, an indication is given by means of the graphic formula [see also Supplementary Chapter I K; Stereochemistry].

Related Substances

7. It is usual to include a test for related substances in a monograph for a medicinal substance. These may be manufacturing impurities (intermediates or by-products) or degradation products or both. When preparation of a monograph is initiated the manufacturer is asked to provide information concerning the nature of such impurities, the reason for their presence, the amounts that may be encountered in material prepared under conditions of good pharmaceutical manufacturing practice and the manner in which proportions may vary on storage, together with an indication of the toxicity of any impurities in relation to that of the substance itself. Where there is only one manufacturer of a substance, pharmacopoeial limits are set in the knowledge that the level of impurities in production batches of the substance will have been accepted by the registration authority after a full consideration of the toxicity studies and clinical trials carried out before the granting of a licence. Such studies and trials will have been carried out on material with an impurity profile that is qualitatively and quantitatively similar to that of subsequent production batches.
Any subsequent changes to the manufacturing process by the original manufacturer or the introduction of material from another manufacturer utilising a different route of synthesis will be subject to the need to demonstrate essential similarity or to provide equivalent data to the relevant registration authority. In some cases a change in production or source may give rise to impurities that are not adequately controlled by the published pharmacopoeial monograph. Appropriate revision of the monograph will be carried out provided that the pharmacopoeial authority is notified of the need and that it is supplied with the relevant information [see paragraph 28 below].

8. Tests for related substances may be specific or general.

9. **Specific tests for named impurities** A specific test is included where a particular impurity arising from the manufacturing process or from degradation needs to be limited on grounds of toxicity or for another special reason. Where an impurity is known to be particularly toxic, this is taken into account in setting the limit; for example, a limit of 1 ppm is specified for hydrazine in the monograph for Povidone.

9.1 Such specific tests usually employ a chromatographic or colorimetric comparison with a sample of the named substance, for example, 4-chloroaniline in Chlorhexidine Irrigation Solution and 4-aminophenol in Benorilate Tablets.

9.2 Where a specimen of the impurity is required in the test, this will be made available as a Chemical Reference Substance unless it is known that specimens of the requisite quality can readily be obtained through the usual suppliers of chemical reagents.

9.3 Specific control may be included within a more general test controlling other impurities; an example is 4-epianhydrotetracycline in the monograph for Lymecycline.

9.4 In other cases, an absolute method is more appropriate. Such a test may be for a group of potentially toxic impurities, e.g., polycyclic aromatic hydrocarbons in Liquid Paraffin.

9.5 Sometimes an impurity may be named in the Pharmacopoeia because it is necessary to use a named substance in its control for analytical reasons, such as different response factors in the specified test method. Examples are iminodibenzyl in Imipramine Tablets, and dibenzosuberone in Amitriptyline Tablets. Typical wording is as follows:

Any spot corresponding to [x] in the chromatogram obtained with solution (1) is not more intense than the principal spot in the chromatogram obtained with solution (2). [Solution (1) contains the substance being examined and solution (2) contains a named impurity [x].]

10. **General tests for unnamed impurities** It is unusual for the Pharmacopoeia to require the absence of a visible spot in a thin-layer chromatogram or the absence of a peak in a liquid chromatogram. Reasons for this include the difficulty of interpreting and defining absence that is a consequence of variations in the sensitivity of a method when performed in different laboratories by different analysts. It is more usual to limit the levels of impurities. This may be done in a simple test by comparison with a spot or peak obtained with a dilute solution of the substance being examined. An example is Methyl Nicotinate:

Any secondary spot in the chromatogram obtained with solution (1) is not more intense than the spot in the chromatogram obtained with solution (2). [Solutions (1) and (2) contain the substance being examined at high and low concentrations respectively.]

10.1 In the absence of evidence that the limit for a particular impurity needs to be set on the basis of its toxicity, control is often provided by a two-level test requiring, say, not more than one related substance at a nominal concentration of up to 0.5% and any others at nominal concentrations of up to 0.1%. The actual limits may be chosen on the basis of batch data for material manufactured in accordance with good pharmaceutical manufacturing practice and will take account of a number of factors, including the dose regimen of the substance and the number of impurities commonly present. An example is Oxetacaine:

Any secondary spot in the chromatogram obtained with solution (1) is not more intense than the spot in the chromatogram obtained with solution (2) (0.5%) and not more than one such spot is more intense than the spot in the chromatogram obtained with solution (3) (0.1%).

Another example, with different limits, is Phenindione:

Any secondary spot in the chromatogram obtained with solution (1) is not more intense than the spot in the chromatogram obtained with solution (2) (2%) and not more than one such spot is more intense than the spot in the chromatogram obtained with solution (3) (0.5%).

10.2 Where it is known that several impurities are likely to be present at significant concentrations, a three-level test may be appropriate. An example is Pentazocine Injection:

By each method of visualisation, in the chromatogram obtained with solution (1) any secondary spot is not more intense than the spot in the chromatogram obtained with solution (2) (1%), not more than one such spot is more intense than the spot in the chromatogram obtained with solution (3) (0.5%) and not more than four such spots are more intense than the spot in the chromatogram obtained with solution (4) (0.25%).

10.3 General tests with an 'open' design such as those described above have the great advantage that they provide a means of limiting the levels of related substances that may arise from modified or alternative synthetic routes not in use at the time the test was elaborated. In this context, thin-layer chromatography

has the advantage over liquid chromatography and gas chromatography that it allows detection of impurities completely retained or those not retained at all by the stationary phase.

11. **Total impurity limits** In gas chromatographic and liquid chromatographic tests, it is increasingly common to limit the total areas of peaks due to related substances. In monographs currently in force the limit for the sum is commonly in the range 1 to 2% but these values are applicable at the end of the shelf-life. This procedure is rarely adopted in thin-layer chromatographic tests, because of the semi-quantitative nature of estimating individual spots and resulting imprecision in expression of results for the totals. This apparent drawback to the use of thin-layer chromatography is largely overcome by means of two- and three-level tests as described in paragraphs 10.1 and 10.2, above.

12. In response to requests from users of the Pharmacopoeia, statements of the approximate real or nominal levels of impurities controlled by tests for impurities have been widely introduced, where appropriate, for information [see paragraphs 14 and 15 below]. Conformity with the requirements will still be determined on the basis of compliance or otherwise with the stated test.

Test design and expression of limits

13. For **identified impurities**, several aspects are taken into account in designing the test. These include the nature of the impurity, its toxicity and the levels likely to be found in routine production. Analytical considerations such as the correction factor (defined in paragraph 16) for the impurity and practical issues such as availability of the impurity as a reference material or reagent also influence the test design.

14. If a major and/or toxic impurity in a material is known to have a significantly different response (more than ±25%) from that of the main peak in the substance being examined in the conditions of the test, the preferred manner of limiting this impurity is to use a reference substance of the impurity. If this is not possible, a reference solution of the substance being examined containing a known amount of the impurity may be used. Using either of these approaches, the concentration limit indicated in the monograph for information in parentheses expresses the approximate limit as a real percentage of the impurity in question. This is also referred to as % w/w. When neither of these approaches is possible, a dilution of the solution of the substance being examined may be used as a reference solution. This approach is also commonly used in tests where an impurity that is known (but not named within the test) has a response within ±25% of that of the main peak in the substance being examined.

15. Unless explicitly stated otherwise, an indication of the approximate concentration limit provided in any test where a dilution of the substance being examined is used as the reference solution should be interpreted as an expression in terms of a nominal percentage of the substance being examined (in accordance with the General Notices) rather than as a real percentage of the impurity.

16. No reference is made in a test to a **correction factor** for an identified impurity unless unavoidable. When used, the term is defined as follows:

> The correction factor ($1/k$) is a relative term, being the reciprocal of the peak response of equal concentrations of one substance relative to that of another in the conditions described in the test.

In the context of a related substances test where a correction factor is quoted for an impurity, unless otherwise stated, this is the expected correction for that impurity in relation to a response of unity for the substance being examined. The way in which a correction factor is to be used in any subsequent calculation is stated in the monograph.

17. Correction factors of less than 0.2 or more than 5 are not generally used. If the difference between the response of an impurity and that of the substance being examined is outside these limits, a different method of determination, such as a different detection wavelength (λ) or a different method of visualisation, is used.

18. For a correction factor quoted in a pharmacopoeial test, the following points are observed:

(a) the peak to which the factor applies is identified unambiguously, recognising the difficulties associated with such identification in chromatograms showing peaks of similar retention times [the use of a sample containing an unquantified amount of the relevant impurity can sometimes be used to assist such identification],

(b) the correction factor quoted is a confirmed value and preferably is based on relative peak areas of equal concentrations of the impurity and the sample under the conditions of the test [alternatively the reciprocal of an absolute figure based on the A(1%, 1 cm) for the detection wavelength used (or similar for other methods of detection) of the impurity and the sample may be used],

(c) the correction factor is stated in a way that does not imply an unrealistic or misleading degree of precision [declaration to several significant figures is not meaningful when placed in context of the nature of the test and the amount of the impurity likely to be present (typically, less than 0.5%) (e.g., 1.4, 2.5, 3.0, 0.5) or 1 decimal place (e.g., 1.4, 7.5) are generally appropriate],

(d) older monographs of the BP may contain the term response factor. The term will be revised to correction factor as these monographs are updated.

19. Identification of peaks is generally not based on absolute retention times since these may be too 'system dependent'; however, advice such as 'the principal peak has a retention time of about x minutes' may be given. In some cases, for example, where a simple chromatogram is expected to show a limited number of impurities, an expected *relative* retention may be given to designate impurities. In other cases where potential impurities have similar retention, a sample containing the components of interest and a sample chromatogram may be provided.

20. **Unidentified impurities** may be limited by reference to a dilution of the solution of the substance being examined used as a reference solution together with an open design of statement limiting 'any' or 'any other' *secondary peak* or *spot*. Such a reference solution may be used in addition to those containing named impurities (any other secondary peak/spot) or, in some simple tests, control of unspecified and specified (but unnamed) impurities may be exerted by means of a comparison between the sample solution and a dilution of this solution (any secondary peak/spot).

21. An indication of the approximate limit concentration for an unidentified impurity would only be given in terms of a nominal percentage of the substance being examined (see paragraph 15) since no assumption can be made about the response of an unidentified impurity. While such nominal

limits are not quantitatively fully transparent and caution is needed in attempting to use them to set a total impurity limit, their use is less misleading than quoting an arbitrary/assumed correction factor of 1 for an unidentified impurity.

Formulated Preparations

22. Many monographs for formulated preparations in the British Pharmacopoeia and the British Pharmacopoeia (Veterinary) also include tests for impurities. In general, wherever possible a test for impurities based on that in the monograph for the active ingredient is included with any necessary modification.

23. Wider limits and/or additional controls may be required for impurities arising on manufacture or storage of the dosage form.

24. Tests for impurities in monographs for formulated preparation are used to control not only degradation products but also by-products of the synthetic route used for manufacture of the active ingredient. It has been argued, for example in the ICH guideline Q3B, that by-products of synthesis have been controlled already during examination of the substance before formulation and that further testing for these impurities is unnecessary. Clearly it would be repetitious and wasteful of resources for tests, often complex in nature, to be repeated routinely simply to demonstrate acceptably low levels of impurities that could arise only during synthesis (as opposed to degradation) of the active ingredient. However, this information is available only to those who know the detailed attributes of the active raw material that has been used. For an analyst who has access only to the dosage form, the profile of synthesis-related impurities offers one means of establishing whether or not the dosage form has been prepared from an active ingredient of pharmacopoeial quality. It is for this reason that such tests are included in British Pharmacopoeia and British Pharmacopoeia (Veterinary) monographs for formulated preparations [see paragraph 3 of General considerations in the introduction to Supplementary Chapter I].

Current and future developments

25. **Transparency** A statement giving the identities of impurities that are known to be limited by the specifications is being added to appropriate monographs for medicinal substances and formulated preparations. For example the monograph for Diamorphine Hydrochloride contains the following information at the end of the monograph:

> *IMPURITIES The impurity limited by the this monograph is:* 6-O-acetylmorphone

This increase in the transparency of pharmacopoeial specifications is of assistance to licensing authorities and others when considering whether the standards in the monograph are appropriate to a new source of supply. It is emphasised that other, unnamed impurities may also be limited. The Commission is actively seeking information that will allow the statements to be extended in future.

26. **System suitability** In chromatographic tests increasing use is being made of system suitability tests to enable the analyst to confirm that performance of the chosen column or plate is satisfactory under the chosen conditions. In liquid chromatographic and gas chromatographic tests, peak separation between impurities and the substance being examined is generally considered to offer the best indication of performance of the system.

27. **Residual solvents** A general test for residual solvents has been included in the European Pharmacopoeia (Appendix VIII L) together with guidelines on its application (Supplementary Chapter IV D). At present, a test for solvent residues is included in a specific monograph only where variation in levels of known solvents requires control, e.g., methanol in Gentamicin Sulfate.

28. The British Pharmacopoeia Commission welcomes suggestions for improving the monographs. In particular, where it is found that significant impurities are not controlled by the monograph, the Commission would be glad to receive details of validated methods that can be considered for adoption.

B. Polymorphism

1. Polymorphism (the occurrence of more than one morphic form) is a function of the internal structure of crystalline solids. Its occurrence cannot be predicted and, as it can be induced in many materials in appropriate conditions, its absence is difficult to demonstrate using a single, specific test. Different polymorphs may exhibit different physicochemical properties such as melting point, dissolution rate and infrared absorption spectrum. In some cases these may affect the handling characteristics of the material, the stability of formulated preparations and bioavailability. Control of morphic form by a manufacturer is necessary during processing of active ingredients and excipients and during production of a formulated product to ensure the correct physical characteristics of the product. Its main importance to the control of medicinal products is in the areas of bioavailability and stability.

2. The morphic form of a readily soluble starting material that is incorporated into a solution, for example, an injection, an oral solution or eye drops, is not usually important. (An exception to this statement might be if the concentration of the solution is such that it is close to the limit of solubility of one of the possible polymorphs.) The morphic form may be important when the material is included in a solid dosage form or as a suspension in a liquid dosage form when the characteristics of the different polymorphs are such as to affect the bioavailability of the material.

3. **Pharmaceutical and medicinal substances** For most substances it will not usually be appropriate or necessary for the monograph to control the morphic form. There are, however, a few monographs that restrict the substance to a single form. This may be done by permitting no deviation from the spectrum/form of the reference substance prescribed or by restricting the melting point range. An example is Carbamazepine where the infrared spectrum is determined without prior treatment of the sample and the melting range permitted excludes the polymorph of lower melting point.

4. Where it is known that the substance exists in more than one morphic form a statement is frequently included in the monographs of the Pharmacopoeia under Characteristics, for example, the monographs for Dextropropoxyphene Napsilate and Spironolactone. In the absence of such a statement, the existence of polymorphism may sometimes be deduced from the tests of the monograph. The most common example is found in infrared identification tests where the analyst may be instructed to prepare a solution spectrum or recrystallise the sample if the spectrum obtained is not concordant with the reference spectrum or spectrum of a reference substance, for example, Prednisolone Sodium Phosphate. This procedure recognises polymorphism but does not limit the form permitted.

5. It is intended to extend the inclusion of explicit statements in monographs for pharmaceutical and medicinal substances as information on the occurrence of polymorphism becomes available. The Commission would welcome information from users of the Pharmacopoeia in order that such statements can be added in appropriate cases.

6. **Formulated preparations** Polymorphism is a potential problem in solid dosage forms, such as tablets, or in liquid or semi-solid preparations where the active ingredient is present as a solid, for example, in oral suspensions. In most cases it is difficult to demonstrate that the material contains the desired polymorph as the process of extracting a sufficient sample of the material in question for analysis may itself change the form of the material. For a solid dosage form where the active ingredient is known to exist in forms with significant differences in solubility, a dissolution test may be the method of choice.

7. Where the active ingredient is known to exist in more than one morphic form and the choice of polymorph is critical with regard to bioavailability and/or stability, the method of manufacture should ensure the presence of the correct amount of the desired polymorph in the preparation.
In future the side heading 'Production' will be used to draw attention to control of morphic form during manufacture in cases where control of morphic form is known to be important.

8. Such Production statements might also include reference to the need during product development to examine drug sensitivity to polymorphic change due to granulation conditions or compressional forces and to make appropriate processing adjustments to control potential variation.

9. The Commission would find it helpful to be advised of instances where control of morphic form is important so that a suitable Production statement may be added. In such cases it would also appreciate receiving details of any validated test methods that will appropriately limit the undesirable form.

C. Bacterial Endotoxin Testing

This section provides an exposition of the Commission's policy and information on its implementation. The guidelines of the European Pharmacopoeia are included as an Annex.

The test for bacterial endotoxins of the European Pharmacopoeia (Ph Eur) is included as Appendix XIV C of the British Pharmacopoeia. This text has been prepared in collaboration with the Japanese Pharmacopoeia and the United States Pharmacopeia.

1. This *in vitro* test is being progressively applied in appropriate monographs of both the British and European Pharmacopoeia in place of the *in vivo* test for pyrogens.

2. Methods for the detection of Gram-negative bacterial endotoxins are based on the use of a lysate of amoebocytes from the horseshoe crab *(Limulus polyphemus* or *Tachypleus tridentatus)*. Addition of endotoxin to this lysate may result in gelation, precipitation or turbidity. The method used in the monographs of the European and British Pharmacopoeias is, unless otherwise stated, that using a gelation end-point.

3. A European Pharmacopoeia Biological Reference Preparation (BRP) of Endotoxin calibrated in International Units (IU) has been established for use in this test.
The current BRP (batch 5) was established following an international collaborative study. It consists of endotoxin from the same bulk as the Third International Standard established by the World Health Organization and the current standard established by the Food and Drug Administration and the United States Pharmacopeia for use in the United States of America (EC-7). Following adoption of the recommendations in the report of the collaborative study[1] global harmonisation of endotoxin unitage has been maintained[2], that is, the FDA/USP Endotoxin Unit (EU) is equivalent to the International Unit (IU).

General policy

4. In any individual monograph only one test is required, either that for pyrogens or that for bacterial endotoxins.

5. In the absence of evidence to the contrary, the test for bacterial endotoxins is preferred, since it is considered usually to provide equal or better protection to the patient.

6. Before including a test for bacterial endotoxins in a monograph, evidence is required that a test, as described in Appendix XIV C, can be applied satisfactorily to the item in question.

7. The necessary information is sought from manufacturers. Companies are invited to provide any validation data that they have concerning the applicability of the test for bacterial endotoxins to the substances and formulations of interest.

7.1 Such data should include details of sample preparation and of any procedures necessary to eliminate interfering factors.

7.2 In addition, any available parallel data for rabbit pyrogen testing that would contribute to an assurance that the replacement of a rabbit pyrogen test by the test for bacterial endotoxin is appropriate, should be provided.

7.3 For formulated preparations, a distinction should be made between any sample treatment necessitated by excipients included in a particular product and any required due to the nature of the active constituent. Attention should also be drawn to any manipulation normally required for the active constituent that is rendered redundant by the composition of the formulation, for example, pH adjustment.

8. In order to set an appropriate limit for bacterial endotoxins it is necessary to know the intended route of parenteral administration (in particular, if the substance may be administered intrathecally) together with the maximum dose as recommended in relevant product data sheets.
The limit for a given material or preparation is expressed as the endotoxin limit (EL) or endotoxin limit concentration (EL). The EL may be expressed in IU of endotoxin per millilitre *for a defined solution* of the material or preparation, or, for some medicinal substances, in IU of endotoxin in relation to a defined quantity of the material (that is, per milligram or, for biologically assayed materials, per IU) of material. The limit, which is stated in the monograph, is usually established on the following basis:

$EL = K/M$

8.1 K, sometimes referred to as the minimum pyrogenic dose, is the maximum number of IU of endotoxin which the patient may receive without suffering toxic
